

GARDENING

Illustrated.
For Town & Country.

A Weekly Journal for Amateurs and Gardeners.

FOUNDED BY W. ROBINSON,

*Author of "The English Flower Garden," "The Wild Garden," "Humble Flowers," "Alpine Flowers," etc.
Founder of "The Garden" and "Even and Home."*

"YOU SEE, SWEET MAID, WE MARRY
A GENTLE SCION TO THE WILDEST STOCK;
AND MAKE CONCEIVE A BARK OF RABER KIND
BY BID OF NOBLER RACE: THIS IS AN ART
WHICH DOES MEND NATURE—CHANGE IT RATHER: BUT
THE ART ITSELF IS NATURE."—*Shakespeare.*

"CALL THE VALES AND BID THEM HITHER COME
THEIR BELLS AND FLOWERETS OF A THOUSAND HUES."—*Milton.*

VOL. XXIV., FEBRUARY 28, 1903.

LONDON:
OFFICE—17, FURNIVAL STREET, HOLBORN, W.C.H

INDEX TO VOL. XXIV.

Comprising Numbers from March 1st, 1902, to February 28th, 1903.

ILLUSTRATIONS IN ITALICS.

A

ABUTILON *indigo*, 184
Saritol, 578
ditrifolium, 301
 Abutilons, the best, 4
A. arnata, 580
A. indica, 512
 culture of, 274
 from seed, 660
Achrocnema atropos, 298
Achillea reptans, 20
agryfolia, 20
aurea, 20
Chamaea, 20
Huteri, 20
moschata, 20
nana, 20
rupestris, 20
tomentosa, 20
umbellata, 20
Achillea, 25, 514, 676
A. chlorhydric, 285
Achilleum, 135
Achilleum cuneatum, growing, 304
 Farleyense in hanging-basket, 611
truncatum var. Farleyense, 220
 trapenlorate, how to treat, 171
Elthonema cordifolium, 80
Elthonemas, 80
 Acapan huts and Crinum, 409
 bloom stems malformed, 407
Azathra caelestis, 288, 502
Agrostemma eupatorioides Walkeri, 532
Agrostis pulchella, 373
 An roots on Vines, 244
 Alkali caustic solution, spraying with, 61
 Almond-tree, pruning an, 457
 Aloe, treatment of, 165
 Alouca Warszewiczii, 454
 Aloysia citrodora, propagating, 310
 Alstromerias, 6, 30, 310, 311
 growing, 620
 in pots, 323
 Alou water for Hydrangeas, 88
 Amaranthus, Globe, 261
 Amaranth, 495
 Belladonna, 537
 growing, 40, 618
 Johnsoni, 439
 leaf diseased, 564
 potting, 600
 Ambrosia mexicana, 604
Androschier canadensis, 460
 American blight in various stages of development, 602
 Anemone, 611
 Anemopsis velvety, increasing, 68
 Anemopsis nana, 161
 Anemopsis species, 342
 Anemone, a fine form of the Wood, 256
caucasiensis, 5
 fulgens from seed, 281; planting over, 174
 Japanese Queen Charlotte, 620
 nemorosa, 256; n. major, 255
 the Peacock, 119
 the Poppy, 5
 terminal, 21
 Wood, 235
 Anemones, 185
 Clusker Cup fungus on, 179
 Crown, in Scotland, 474
 forcing, 499
 hybrid Japan, 421
 Poppy, 412; from seed, 35
 St. Bridget, flowering in early spring of Grasshill, 191
Angraecum sesquipedale, 672
 Annuals, 295
 and perennials, 28
 etc. for early flowering, 418
 for the flower garden, 309
 for town gardens, 58
 hardy, 469; and other flowers, starting, 58
 in pots, culture of, 75
 in the garden, 300
 mulching, 95
 pretty, 311
 Anagallis breviflora, 612
 Anomatheca crenata, 171, 173
 Anona squamosa, 54
Asteriscus rostratus, 613
 Asteriscus and Festschenons, 518
 Ancharium Scherzerianum, 451
 Ast, the common, 672
 Asta, 392
 black, destroying Cyclidius on

Ants, destroying, 105, 171
 in a Rose-bed, 345
 in greenhouse, 263
 in lawn, 234
 plague of, 112
 Apiary, seasonable work in the, 53, 181
 Aponegeton distachyon, 497
 Apparatus, heating, 568
 Apple, a good hardy, 640
 a good late, 560
 Allington Pippin, bush-trees of, 478
 and Pear trees, London, 301; insects on, 229
 aphid, the, 268
Autumn Pearmain, 531
Belle du Bois, 637
Blenheim Orange, said to be an open cross, 437, 486, 573
 blossom, thinning, 97; weevil, 658
 Cox's Pomona and ranker, 183
 culture in S. Wales, 517
 Dutch Codlin, 42
 English Codlin, 42
 Fire-crowned Pippin, 508
 Franklin's Golden Pippin, 630
Gibson's Scarlet, 604
Gibson Mundi, 657
 Kewick Codlin, 42
Lane's Prince Albert, 500
 leaves, mildew on, 198
 London Pippin, 508
 Lord Grosvenor, 42
 Lord Suffield, 42
 Manks' Codlin, 42
Mex de Manque, 643
 Newton Wonder, 501
Pontwood's Autumn, 548
 Ripper, 660
Sandringham, 481
 shoots and bloom diseased, 212
 the Custard, 64

 Transparent, 12
 Warner's King, 625
 Wyken Pippin, 643
 Apples and Pears, late, 601; thinning, 229
 bush, for small gardens, 11
 Codlin, a good crop of, 42
 cordon, 37
 espalier, 432
 for Exmoor, 606
 gathering, 394
 green, rooking, 96
 highly-coloured, early, 604
 injured, 105
 keeping, 11, 345
 late-keeping rooking, 410
 planting, 658
 scarcity of, 416
 six good eating, 407
 some good Codlin, 42
 spotted, 580
 table, 616
 the larger, 625
 twelve leaves, 38
 twelve varieties of aromatic, 174
 weighing & measuring, 500
 Apple-tree, insect on, 320
 leaves, grub on, 202; insects on, 232, 320
 standard, transplanting, 11
 unhealthy, 635
 Apple-trees, American blight on, 96, 391, 438, 477, 533
 bush, planting, 606
 cankered, 122, 531, 607
 decaying, 101
 diseased, 183
 espalier, training, 506
 insects on, 105, 259, 272
 manuring, 544
 mistle scale on, 32
 producing small fruit, 642
 pruning, 446; three-year-old, 555
 spraying, 108; with Paris green, 64
 trained, 628
 unhealthy, 208, 402
 Apricot, four-year-old, 112
Moorpark, 401
 Apricots, Cherries, and Peaches, wash for, 608
 falling, 466
 fruitless, 383
 pruning, 638
 stopping and disinching, 93
 Apple-tree, a grass growing, 112
 canker on, 406
 Apple-trees not blossoming, 434
 April Rose, 600

Aquatic, a pretty, 580
 soil for, 652
Aquilegia alpina, 138
 Bertoloni, 138
 pulchella, 138
 canadensis, 138
 chrysantha, 138
 caerulea, 138
 fragrans, 139
 glauca, 139
 glauca, 139
 leptoceras, 139
 Skinneri, 139
 Stuarti, 139
 viridiflora, 139
 vulgaris, 139
Arcadia albida, 650
 Aralia Sieboldii, propagating, 261; in a water-lactary, 28
 Arumaria excelsa for furnishing, 206
 falling, 544
 lifting, 607
 Arumia albena, 316
 Arum, a Rose-covered, 661
 Arch, climber for, 100
 Arches, pillars for, 640
 Arctostaphylos, 386, 425, 453
 Aristochia pycnantha, raising, from seed, 25
 Arrangement, bedding, 652
 Artichokes, cultivating, 109
 disease, 64
 globe, 367; from seed, 555; protecting, 369
 Artichokes, Jerusalem, 2; and the globe, 64
 Arum leaf damaged, 62
 Lily, decaying, 106; leaves turning brown, 39
Pelle von Stuttgart, 230
 lilies, 288, 672; and Spiraea, summer treatment of, 180
 small-flowered, 230
 Arums, lifting, 445
 yellow, growing, 139
 Arundo donax at Boscombe, 157
 Donax, 157; D. persicolor, 157
 Arum, 157
 Asclepias tuberosa, 149
 Asparagus, 392, 618
 and other Kales, 221
 bed weedy, 262
 beds in winter, 570; manuring, 610
 beetle, the, 285, 102
 culture, 336
 cutting, 96
 feeding, 40, 221
 lifting light green, 671
 lifting, 613, 684
 French system of growing, 249
 newly-planted, 150
 ultrae of soil for, 275
 on the French system, 250
 planting, 108, 147, 573
 plumous from seed, 696
 rotting, 183
 securing the stems of, 105
 seeds, sowing, 123, 183
 Sprenger, 102, 161; seeds, 303
 summer treatment of, for forcing, 251
 Aspidistra, 652
 falling, 17
 leaves splitting, 49, 236, 348
 Aspidistra, 321, 601
 potting, 431
 with short leaf-stalks, 622
 Aspidium flaccidum, 11
Vitis australiensis, 649
 Aster acris, 521
 Chim, in border, 305
 Townsendi and A. hispidus, 130
 Aster, a bed of China, 309
 China, 265
 destroyed by insects, 216
 falling, 303
 outdoor sown, 109
 Aubrietias, 435
 increasing, 419
 Aucubas, berried, 586
 raising, 32
 Auriclea, an alpine, 373
 treatment of, 115
 seed, sowing, 198
 Auriculas, 201, 373
 alpine, 223
 in pots, growing, 523
 outdoor, 185
 Autumn, the mild, and its effect on vegetables, 656
 Avary, outdoor, 620

A. indica, a cuttably grown, 181
 India, 110; after flowering, 152; falling, 160
 leaves turning brown, 288
 radialis, 152, 230; after flowering, 82, 122; in pots, 506
 Azaleas, 239, 267
 and Camellias, potting, 165
 and greenhouse, 166
 good hardy, 456
 hardy, 274
 in leaf-condition, 108
 India, 254; for linnse furnishing, 612
 not flowering, 321
 planting, 406
 potting newly imported, 573
 thrip on, 53

B

BALCONY garden, a beautiful, 498
 Balsams, 3
 in pots, 159
 Bamboos for the conservatory, 261
 Bank, peat, plants suitable for a, 111
 sandy, stony, plants for, 31
 steep, covering a, 497
 Banks transformed, 371
 Raspberry berries, 490
 rutinum, 580
 Bark of trees splitting, 309, 429, 630
 Baskets, Ferns and bulbs in, 622
 hanging, 286
 Bean, broad-leaf, 449
 Johnson's Wonderful, 56
 Beans and Broccoli, 317
 Broad, 84; falling, 247; or Long Poi, 613
 dwarf, forcing, 583
 early Runner, 136
 for exhibition, 236
 French, forcing, 1; Runner, 234
 Kijiner, 421; preserving, 419
 large Runner, 108
 Runner, 519
 Bedding, plants for, 587
 Bed, along, 211
 plants for, 58
 shaded, plants for, 186
 utilizing a shade, 426
 Beds and borders, 370; clearing, 621
 for hardy flowers, 387
 Beech Coccus, the felted, 468
 Beech-trees, plants under, 189
 Bee-lead, 543
 keeping, starting, 235
 Best autumn treatment of, 414
 foreign, 492, 517
 in bank, 145
 Bert, Crinum Globe, 25
 sowing and thinning, 121
 Sponck, 84, 290
 Sutton's Globe, 571
 Beetroot and Carrots, 513
 falling, 628
 Beetroot, storing, 416
 Begonia, a double-flowered, 502
 a fine, for hanging-basket, 191
 a fine-leaved, 320
 double, Dorothy Hardwick, 451
 fuchsoides, 512
 glaucophylla, 100
 Gloire de Hollande, 17, 142, 573; in-creasing, 197, 612

VEGETABLES.

FORCING FRENCH BEANS.

Or all French Beans for growing under glass there is none to equal Osborn's Forcing. There are various ways of sowing the seed and bringing the young plants forward, but modes of doing this which might be the best in April or May would not answer very well during the shortest days. For instance, when the spring is well advanced the seed may be sown in boxes or in 8-inch or 10-inch pots, in which the plants will bear pods; but if this were done now many of the seeds would be liable to decay before they germinated, and the plants would not grow so strongly or rapidly as they will if the seed is sown in small pots, from which the plants will be transferred into larger ones as soon as large enough to handle. Our plan at this season is to fill a number of 3-inch pots half full of a light rough mixture of loam and horse-droppings, and to put six or eight seeds into each. The soil is pressed down as firmly as possible, and some of it is placed on the top of the seeds to the depth of 3/4-inch or so. They are then placed in a house or pit in which the temperature ranges about 60 degs., and here they get little or no water until the first leaves are formed and a few roots have been made. This treatment prevents all damping or decaying, which must be guarded against at this season. When efficiently advanced in growth to bear and require water they have a plentiful supply, and then they grow freely. It is a great advantage to have them near the light and in rather a dry atmosphere.

As soon as the plants are 5 inches or 6 inches high, and have made half-a-dozen leaves each, it will be found that the small pots are well crammed with roots, and they should then be shifted into larger pots. The 8-inch ones are the best. They should be well drained, and the potting mixture should consist of rough loam and horse-droppings. Fine soil should be avoided. After potting they may be returned to their old quarters, but water should be given sparingly until the roots have taken possession

of the new soil, when more must be given. Those who wish to keep up a constant supply of Beans should sow a quantity every fortnight. At times we have placed only one of the small pots of young plants into the 8-inch one, but where space was limited we have put three small pots into this size. When this can be conveniently done it is a profitable way of growing them, as a great many more Beans are secured from the pots with the most plants than the others, and the space required for both is just about the same.

When in bloom the flowers should be kept as dry as possible, as the fruit forms with more certainty than when the blooms are damp. We never allow any of the growths to fall over the sides of the pots, as this checks them; but when any of them are so tall or weak as not to be able to stand without support, pieces of birch from old brooms are put in to hold them up. Osborn's Bean does not, however, require so much attention in this way as such kinds as Canadian Wonder, which cannot be grown without support. As soon as any of the pods become large enough to gather they should be removed from the plants at once, as there is nothing so much against the production of a long succession of fruit from the same plants as allowing some of the first formed pods to become old. Liberal quantities of liquid manure assist old plants to keep on fruiting, but we do not approve of this, as plants are so very easily raised, and young vigorous ones are always the most fruitful.

LEEKs.

WHEN Leeks are grown to produce large, long blanched stems to present at exhibitions, the trouble involved in such production usually greatly exceeds the results, except for such particular object. But no one wants such huge stems for table use as these show plants commonly are. As a rule, judges ignore the requirements of the table, and think only of size of stem, if allied to considerable blanched length and whiteness. But for table use, stems equally well blanched and pure in colour, that are but one half the dimensions are best—that is, instead of being as big round as a broom-handle, more

nearly represent the size of a whip handle, as these are so much more tender when cooked, and are for that reason so much more enjoyable. The exhibition stems are the product generally of very early sowing, early planting in trenches half filled with manure, frequently, later, liberally watered with liquid-manure, and blanched with bands of brown paper. Even then the stems are sometimes enclosed in drain-pipes, and these are partially backed up with soil, no trouble being spared to get the stems long, stout, and very white. But to have a long supply of Leeks for table use—and good stems well grown and blanched under ordinary culture when well cooked make a delicious dish—it is enough to plant them from the seed-pots or boxes when 6 inches in height out into shallow trenches into which a moderate dressing of manure has been put, and which is well mixed with the soil. As the plants grow give occasional liberal waterings, and get good growth on to the plants before commencing to earth them up. Before doing that remove a few of the lower leaves. Good blanched stems should be about 10 inches long and very clean.

A. D.

FORWARDING VEGETABLES & OTHER THINGS ON BEDS OF LEAVES.

It is astonishing how much can be accomplished in cold-pits and frames, which at this season are so useful for forwarding crops for early use. During the first four months of the year the soil is very cold and the weather very changeable, but with a little warmth and glass shelter (covering the glass on very cold nights) plants grow rapidly, the crops often being from one to two months earlier than those on sheltered, warm borders. It is a very simple matter to provide a little warmth. This may be done in many ways, and often at very small cost. In country gardens leaves are abundant, and even in small suburban gardens many leaves may be stored by attention in autumn and winter. If collected in a heap and kept dry they do not rot. If a little stable or other fresh manure is added sufficient heat will be forthcoming. Last year I made a bed large enough for a three-light frame with tree-leaves and green Box that had been clipped off some big bushes. On this I

grew a crop of Radishes and Potatoes, and when these were cleared off a crop of Melons was taken from the same bed. Strong heat is not desirable. Asparagus, Turnips, Radishes, French Beans, Lettuces, Carrots, Cauliflower, Peas, and numberless other things are raised in these beds. In such beds, too, Hyacinths, Tulips, Narcissus, and other bulbs are grown, and now (middle of January) I have Narcissus, such as *maximos*, *Horsfieldi*, etc., standing on well, these being stood on a bed of leaves, etc., in a cold-pit. Lily of Valley is satisfactory when put in such places for April and May flowering. Deutzias, Dielytras, and Spiraeas also do well. For raising seeds, etc., from February onwards these beds are excellent. I cover the leaves, etc., with ashes to prevent slugs getting at the seedlings. When rotted, the leaves make fine material for dressing land, potting, and a number of other uses. J. CROOK.

NOTES AND REPLIES.

New Pea Ideal.—This Pea can be recommended to amateurs as well as gardeners. It is one out of a great number grown for trial at Chiswick last year that gained an A.M. at the hands of the Vegetable and Fruit Committee on June 10, 1901, the raisers being the Messrs. Sutton, of Reading. Ideal may be described as a first early dark green Marrow Pea of excellent table quality, and a heavy cropper. Another advantage is the fact of its coming to maturity at the same time as the round, white-seeded kinds, while to this must be added that the haulm does not exceed 3 feet in height. As the time is at hand for making the first sowing of Peas outdoors, I would advise that Ideal be given a trial, and shall be much surprised if those who do so are not satisfied with the results.—A. W.

Parsnips.—It is fortunate for the grower of these very useful roots that we have very few varieties. Practically there are but three in ordinary cultivation, the Hollow Crown, the most widely grown and having several designations, the whiter-fleshed Tender and True, a particularly nice selection from the former, and Student, a true stock of which has raised necks and not unken ones as the Hollow Crown has. Parsnips are neither the best nor most profitable when very long. Judges at exhibitions do, as a rule, favour roots ranging from 24 inches to 30 inches in length if they be smooth and, for their length, handsome. But by far the sweetest and most marrowy flesh is got on roots that are but 12 inches in length, have nice broad shoulders, and good, tapering, firm roots, literally all flesh, and when properly cooked of delicious quality. Parsnip ground should not be freshly manured, yet be fairly good and well worked. The plants may be hot 0 inches apart in the rows, the aim of the grower being rather to get many of medium size than fewer of abnormal length.—A. D.

Turnips for late use.—There are few places where Turnips are not appreciated all through the year for flavouring soups, etc. This being so, everyone should endeavour to provide a supply over so long a season as possible. It is during the spring months this is the most difficult, but this may be overcome to some extent by a little forethought. For years I have made it a rule to sow very late a small quantity of Chirk Ceeble Bleekstone. This kind is very hardy. I allow the roots to remain where they are sown till the tops begin to run to greens, when they are pulled up, cutting off the greens about 2 inches from the head. Then the roots are laid in coil under a north border, and when growth begins again they are lifted, cutting the roots and tops and covering them with soil, moving them occasionally to prevent rooting. In this way I generally keep them till Turnips come in in the open border. In seasons when I have been short of Turnips I have taken up the small ones out of the main crop about Christmas, cut off the rough leaves, and laid them in a drill 3 inches or 4 inches deep. In this position they make new growth and are not affected by frost.—J. CROOK.

Brussels Sprouts.—Whilst many gardeners prefer to sow seeds of Brussels Sprouts under glass early and thus raise plants that, got out early into rich, deep-worked soil, grow by the autumn to great height and size, yet, as a rule, the Sprouts produced are large, coarse, and

quite unfit for ordinary use. It is wiser to sow seed outdoors at the same time that Antomn (Giant Cauliflower seed is sown, in shallow drills and thinfy, taking care to net them over to keep off birds. Such plants are hardy, starchy, and transplant well in good time. Generally, in small gardens room cannot be found for such plants until early Potatoes or Peas have been taken off. If the ground be just ploughed over and levelled, then holes dibbled into it in rows 2½ feet apart, the Brussels Sprout plants being put out into them and well soaked in with water, growth will be hard, if steady, at least sure. Stems will be hardened in time, clothed with small but hard, green Sprouts, perfect ideals of what Sprouts for table should be.

Up-to-Date Potato.—Few Potatoes are so universally grown as this, for it is the market growers' main crop sort, and at the present time hundreds of tons are stored in this locality, for it is in daily use nearly all the year round. In this locality no variety I have yet tried has turned out such sound, handsome tubers as this. It is one of these kinds that does not require very high manuring or any special culture to ensure tubers quite large enough for cooking. The brightest and best formed tubers are grown in rather poor soil, and anyone giving it a trial for the first time will do well to select soil that was well manured last year. Do not put on any fresh manure, but rely on deep cultivation. Give plenty of room, and keep the surface soil frequently stirred. The only fault I have heard from retailers is that it is too large for selling in small quantities. It is essentially a main crop sort, and if planted in March or April may be stored quite ripe in September. As it is a strong grower, 3 feet between the rows and 1½ feet from set to set will give far better results than closer planting. From a single tuber set out quite clear of other crops I have often dug over a gallon tubers.—JAMES GROOM, Gosport.

Flavouring Onions for summer use.—It often happens that there is a scarcity of Onions even for flavouring. Unless a unusually cool stove is available for Onions a large percentage of the bulbs becomes soft and outgrown. In this state they will not keep long. Some sorts of Onions keep better than others, and where late ones are desirable, varieties with this character should be grown, if only in small quantity, but without the suitable store there is sure to be this trouble with any kind. To tide over this season of scarcity many gardeners find it a good plan to select some of the best of these grown-out bulbs and plant them out in the garden in rows about 10 inches apart. This is done in February in favourable weather. An odd corner or a row or two put out between newly-planted fruit-bushes—it may be Gooseberries or Currants—answers. All that can be expected from them is green tops, the root will be gone entirely; but for flavouring these answer the purpose very well. This course, while it provides for a time of dearth, removes at the same time a source of waste, for Onions, when grown out, have lost their value in the dry store. These of your readers, then, who have plenty for their present use and a prospect of scarcity later on would do well to give this matter their careful thought while there is material available, and this is particularly important with those who require soup-flavouring vegetables almost daily. It is well known that Onions will endure a good deal of frost and cold, and a store for them need not be strictly frost-proof so long as it is dry. For this same reason there is no need to hesitate about prospective weather for the outdoor planting so long as it is mild and the ground in fairly good working order at the time it is done.—W. S.

Early Lettuces.—Where accommodation for wintering Lettuces does not exist, and an early supply is required, seed of a quickly-maturing variety should at once be raised under glass in a temperature of 45 degs. or 50 degs. If sown in a pan or box and placed on a shelf close up to the glass nice stocky plants will result. Prick these off when large enough (if a frame is not at liberty) into other boxes and grow them on as hardily as possible. By the time there is a danger of the plants becoming crowded a frame in which early Potatoes have been forced should be reserved for them. No preparation will be required, as there will be quite enough soil for them, and just sufficient

latent heat remaining in the hot-bed to give the plants a start. Set out the plants 9 inches apart each way, water and afford shade until the roots have taken hold of the fresh soil. Give air in the morning to prevent the plants getting drawn, but close early in the afternoon to promote quick growth. Water whenever the plants require it, and an overhead sprinkling with a fine roset can be also beneficial at closing time, particularly on bright, sunny days. By careful attention to these few details excellent Lettuces may be grown in a frame or a slightly heated pit. For this purpose the cabbage varieties are the most suitable, among which are Golden Queen, Paris Market, Harbinger, Forcing, and Perfect Gem, all of which can be recommended.—A. W.

Jerusalem Artichokes.—These may now be planted as they are quite hardy, and there is always more than enough work to get through in the garden in March. Moreover, the tubers only shrivel if left too long in the storehouse. The new white Mammoth is the best variety, being of better shape and quality than the ordinary kind. Jerusalem Artichokes are often grown for many years on the same ground, and in a success part of the garden; but this is a mistake, as not only the size but the quality also are thereby impaired if a fresh site cannot be given them every year, at least some fresh soil from the frame yard, or, falling thin, from another part of the garden, should be dug in deeply, together with a liberal quantity of well-rotted manure. The ground should be made firm and the tubers planted a foot apart in rows 18 inches apart. Where ground is plentiful 2 feet is not too much, as the more sun and air the plants get the finer the yield will be. Plant in moderately deep drills, and make the ground firm by treading. A mulch of old Mushroom-manure, applied when the plants are a few inches high, will prevent rapid evaporation, and if a couple of good soakings of liquid-manure can be given during the summer so much the better. The smallest and most inferior tubers are sometimes saved for seed, instead of which medium-sized, well-shaped ones should be selected, these being the only guarantee for a good all-round crop the following season.—C.

Tomatoes.—To keep up a succession of fruiting plants, a little seed should be sown at intervals of a month or so from now onwards. These plants are often injured from the first by pinching the pan or pot containing the seed in a hotbed, causing the seedlings to come up very weak, and some time is lost before these can be made sturdy plants. If the seed is sown thinly and the pan stood on a shelf near the glass in a warm greenhouse growth will be much slower at first, but the plants are much better later on. Young plants raised from seed sown last autumn should be potted on as required, but no attempt should be made to force growth by placing them in too much heat. A warm greenhouse with rather a dry atmosphere suits them well. They should be always kept well up to the light and receive ventilation whenever the weather permits. Stronger plants coming into flower should be assisted with weak liquid-manure. Shorten back the foliage somewhat where necessary to expose the flower-truss to light and air, and the blooms should be gone over daily with a feather or soft brush to assist the fruit to set. Winter fruiting plants are still cropping well, and they receive every support in the way of surface dressings of rich compost and a dusting of bone-meal. Heavy dressings of soil are not necessary; in fact, such may prove harmful at the present season, it being better to afford these at short intervals and in small quantities. When the plants are strong and healthy the tops may be pegged down in the border, and they quickly make fresh roots in the soil, or they may be pegged into pots filled with rich compost, and when sufficiently rooted covered from the parent plant, and a good batch of plants will be obtained that will commence to fruit at once. All fruit should be cut as soon as it is coloured, so as to relieve the plants as much as possible. Frogmore Selected is a good variety for winter work.—P.

Early Potatoes.—Kidneys or any early varieties for frame culture and planting immediately after the new year need not now be checked, as it would be an advantage to allow

them to sprout and have strong shoots by planting time. Other seed which may not be wanted until February or March should not be sprouting yet; but if it is, check it as much as possible by a cool atmosphere, and if some persist in growing after that it is best to break the meet forward of the shoots off and let the back ones take their place. Shoots 1 inch or 2 inches in length now would be of no use on seed intended for planting in March, as they would be much too long by that time to be handled or put under ground. It is a difficult matter to keep the shoots from growing when once they have fairly begun to push; it is much better to keep them back now than allow them to grow and keep them at a standstill further on. Nothing worse could happen to seed Potatoes than having

PLANTS AND FLOWERS.

CASSIA CORYMBOSA.

OCCASIONALLY in some old-fashioned garden a large plant of this Cassia may be found which can be depended upon to flower well every summer, and during the winter it is kept in the conservatory, or somewhere just clear of frost. In some of our public gardens, too, it may be seen growing outside during the summer associated with other tender subjects. The excessively hot weather of recent summers has suited it well, for it has given quite a mass of its golden blossoms, which lasted for some time. It is, as a rule, far more frequently

GLOXINIAS IN COOL GREENHOUSE.

ALTHOUGH the Gloxinia is classed as a stove plant, it is surprising what a fine display can be had in a cool greenhouse without much trouble when one has not a stove to grow the plants in. About the middle of February I make up a hot-bed for Cucumbers. When the temperature of the frame is about 65 degs. or 70 degs., I put up my bulbs and place the pots around the sides of the frames, setting a Cucumber plant in the centre of each light. By the time the Cucumbers reach the sides of the frames the Gloxinias have made a start. I then transfer them to theinery, the vines by this time being in full leaf affording sufficient shelter. With a little fire-heat and the moisture from syringing the Gloxinias make good progress. If there should be any blank places in the foliage of the Vines it is advisable to shade the plants with a few sheets of paper during the hottest part of the day. They are shifted on into larger pots as they require it. This is one of the points that should not be overlooked, as I find the Gloxinia enjoys plenty of space for its roots. While a great many plants flower best when pot-bound the Gloxinia is quite the reverse. I keep them here until they begin to show flower, then I remove them to the greenhouse. The house is span-roofed, with a path down the centre, and four tiers of staging each side. On the top I have a row of Tomatoes in pots, trained up the roof by means of string or wires. Under the shade of the Tomatoes I let the Gloxinias throw up their handsome blooms. The house is very pleasing, with the huge red and green Tomatoes hanging down, while underneath are the soft delicate blooms of the Gloxinias, with all shades of colour imaginable. After flowering the Gloxinias are gradually dried off. When quite dry the soil is removed, the bulbs placed in a shallow box, and covered with silver-sand. This keeps them plump through the winter. H. SUMMERS.

Silver-street, Godmanchester, Hunts.

BALSAMS.

It is difficult to understand why so few people cultivate Balsams. To have Balsams in flower in May one should sow the seed in February. I prefer doing so in shallow, well-drained pans in soil largely composed of rough leaf-mould over the crocks, with finer mould and turfy soil above, thinly scattering the seeds and barely covering with soil. Whilst the soil should be kept moist in a house where the temperature ranges from 55 degs. to 60 degs., too much moisture is apt to result in the seedlings damping off. It is safest, also, to get them into pots as soon as they are large enough for removal, and not wait until they begin to get too thick, giving them a shelf where they will have plenty of light. At the second and subsequent pottings one may be liberal with regard to the compost, adding to the leaf-mould and turfy soil some old manure from a heap that has stood a few months. In a compost of this character Balsams grow freely in a house where temperate heat prevails. Balsams should not be allowed to become dry. In a warm house where any attempt is made to push them into bloom they will imbibe a deal of water, and liquid manure occasionally administered a few weeks before the buds open will improve the quality of the flowers. Green-fly sometimes attacks plants that are apparently healthy; but, as a rule, heat and overdryness are the cause of their appearance. Gently syringing the plants before they bloom, or, if in bloom, fumigating, will quickly disperse them. Well-fed plants are least likely to suffer from green-fly. Balsams are extremely showy when in bloom, may be had in flower for many months by occasional sowings, and are not difficult to manage. W. F.

TREE-CARNATIONS.

THESE require very careful treatment during the winter. Tree-Carnations are often grown in dark-houses or pits, but the plants become weakly, and the flowers are few and of poor quality. I have seen them doing well on tier-above-tier stages in lofty lean-to houses; but a low span-roofed house running north and south suits them best. This should have a tolerably wide bench in the centre, and narrower ones on each side. The stage should be covered with rough deal, shingles, or shingle, and the plants

Cassia corymbosa.

them stored in mounds during the winter, and allowing them to remain in that state until they have become a mass of young shoots and roots, as the shoots emit roots when growing in this manner, and they all derive vitality from the seed. Many who possess seed Potatoes may be unable to keep them thinly laid out in winter, but everyone may turn and air them, a practice that is very beneficial. When we are obliged to keep more than we approve of on the top of each other in autumn, we always find some means of spreading them out thinly in spring to harden the shoots before planting. The very late sorts do not start freely into growth at this season, or, indeed, during the winter, and it is kinds like these that should be massed together, when massing must be done, and, as the early ones are cleared out and planted in spring, these can be spread out in their places.

met with across the channel than it is in this country. Cassia corymbosa is a native of the neighbourhood of Banase Ayree, and was introduced in 1796. It is of easy culture, succeeding, as it does, in any ordinary potting compost. The principal thing to be observed is the thorough ripening of the wood towards the end of the summer. In some gardens on the south coast it stands the winter if given the protection of a wall and flowers freely every year. Cassia corymbosa need to be planted out every season in the Royal Horticultural Society's gardens at Chiswick, and flowered splendidly. On the approach of frost the plants were lifted, cut down and potted, and placed in a house with Pelargoniums until required again for the flower garden. They invariably did well treated thus. Plumbago capensis, given the same treatment, also flowered splendidly.

arranged not too closely. If there is any greenfly on the plants, fumigate them on two or three evenings in succession, and syringe them with tepid water the first fine day after, repeating the fumigating every three weeks in winter, as, if aphid once gets a foothold, it is difficult to eradicate, and the plants soon become sickly. To ensure a constant supply of flowers in winter a little artificial heat is necessary, from 50 degs. to 55 degs. being a suitable temperature, and the rubble on which the plant stands should be moistened occasionally; admit air liberally in mild weather. The less artificial heat given to plants intended to flower in spring the better, and it is from these the cuttings for next year's stock should be taken. Keep the soil in the pots free from weeds, and loosen it occasionally with a pointed stick to admit air. If the plants are well rooted, liquid-manure of a weak nature may be given, say, once a week, and I have known native guano given with very good results; but artificial stimulants must be used with caution. Avoid watering in dribslets. Be sure the plant wants water, then give sufficient to moisten the ball through. Disbudding is seldom practised; but it is best to remove the small buds which usually cluster around the terminal one—this will increase its size and quality. Support the growths with neat sticks.

CHROMER.

THE BEST ABUTILONS.

A CAREFUL selection of the original species of Abutilons is now absolutely necessary, there being so many garden varieties, and, though they do not bloom so freely in a small state as some of the hybrid forms, half-a-dozen or so must have a place amongst the very best.

A. DARWINI, which is quite a shrub, with orange-red flowers, is interesting as having, in conjunction with the white-flowered *Boule de Neige*, laid the foundation of the numerous garden varieties, among which, however, are some in the way of, but superior to, the typical *A. Darwini*.

A. INSIPIDE is widely removed from any of the others, and is also of slower growth. The leaves of this are large, heart-shaped, and of a bright-shining green, while the flowers, which are borne in axillary pendulous racemes, have more spreading petals than any of the preceding, thus forming a shallower bloom. The colour of the flower is purplish-rose, with darker veining. This plant, which is also occasionally met with under the name of *A. igosum*, is very uncommon, though a most desirable member of the genus. It requires rather more heat than is necessary for the other Abutilons.

A. STRIATUM, a rapid-growing plant, is well suited for a conservatory pillar or some such spot. By continuous pinching it may be induced to flower in bush form, but is more effective when allowed to grow freely. The lobed leaves of this species are of a bright-green colour, while the drooping blossoms are of an orange-yellow, thickly reticulated with red. A thriving specimen of this Abutilon will flower more or less continuously throughout the greater part of the year.

A. VENOSUM is the grandest of all the Abutilons. The deep green, large, palmate leaves are very ornamental, while the blooms are such as much as 3 inches in diameter, and as the flower-stalks are often nearly a foot in length they are very conspicuous, especially where the plants are trained to a roof or pillar. The colour of the flowers is bright-orange, veined with red.

A. VEXILLARIUM is a slender yet free-growing climber, or rather a plant of rambling habit, that may be employed to furnish the roof or pillars of a greenhouse, while it is far hardier than is generally imagined. There is a great difference in colour between the two portions of the flower, the calyx being bright crimson, and the petals, which partially protrude therefrom, are yellow. This species is also known by the name of *A. megapotamicum*. There is a variety of it whose leaves are mottled with creamy-yellow, and very pretty it is in a small state under glass, but when planted out and growing vigorously the variegation frequently disappears to a great extent. *A. vexillarium* is a most continuous bloomer, but despite this fact and the bright colouring of its blossoms it does not appear to have been of much service to the

hybridist. A few years since a number of seedlings between it and several garden forms were raised, but on flowering it was found that the infusion of *vexillarium* blood had by no means improved the hybrids, the species being superior to any of the seedlings. Such being the case, the whole of them were discarded. The next species to mention is the Brazilian

A. VITIFOLIUM.—A native of Chili, and hardy in the more favoured districts of England and Ireland. This is quite a bush, whereas porcelain-blue flowers are borne during the month of May. There is also a variety with white blossoms.

Abutilons with variegated leaves are rather numerous, for besides the form of *A. vexillarium* previously mentioned there is a beautiful variegated variety of *A. Darwini*, known as *tesselatum*; the leaves of *A. Thompsoni* and its double-flowered form are mottled with a creamy hue, while the warm-house *A. Sellowianum variegatum* has handsome marbled leaves.

NOTES AND REPLIES.

Coleuses.—I have long since regarded the keeping of old Coleuses through the winter as a waste of time and trouble, to say nothing of the room they take up, and the additional heat necessary to carry them through. I do not think anyone would keep them after October after rearing a batch of plants from seed. Seedlings grow more rapidly, when once a start is made, than do old plants, and there is a freshness about young plants that old ones do not possess. To have plants for greenhouse decoration in June and July and onwards seed should be sown in March in a house where the minimum temperature ought not to fall below 60 degs., and no better place can be had than a propagator erected over the hot-water pipes or near the stove. Pans of light, sandy soil, with ample drainage, are necessary for their successful culture, and all the light possible should be given them, encouraging a moist, humid atmosphere, yet avoiding overwatering. The best coloured sorts will soon become apparent, and potting off separately should be undertaken when large enough for this. I have grown them from a March sowing, and had nice specimens in 48's by the middle of July, using nothing but old turf soil and silver-sand, with a little leaf-mould added.—LEAHUNT.

Climbing plants.—It often happens that the climbing plants employed to cover an end wall of a conservatory, or to furnish the roof, are the least satisfactory of its occupants. This is especially the case when the plants chosen are naturally of too strong and vigorous a habit. In this case they either smother everything else in the house or have to be so severely cut in as to interfere with their flowering, and, what is even more detrimental to their well-being, they generally exhaust the limited quantity of soil that can be afforded them to grow in to an extent that does not admit of its fertility being kept up by additions of manuring. Where such a state of matters exists it is much the best to remove the old plants and replace them with others of a less rampant habit; this will give an opportunity for completely removing the soil. This is essential, as with perennial plants of this kind comparatively little can be done in the way of removal without destroying the roots to an extent that would be injurious. Whatever is to be done in the way of cleaning conservatory climbers should now be carried out whilst the plants are comparatively at rest, as during this time the work can be done much more effectually as well as with less injury. An effort should be made to completely eradicate mealy-bug and scale, for where nothing is done beyond periodically freezing the plants from a portion of them the work has to be repeated indefinitely, the result being a continuous expenditure of labour, with more or less injury to the plants.

Fuchsias.—Young plants struck from cuttings at the latter end of summer, and that have been kept growing slowly in an intermediate temperature, will now require larger pots, for if they are allowed to become at all cramped from want of pot room they will not move freely afterwards. Such as have occupied 5-inch or 6-inch pots may be moved into others 2 inches or 3 inches larger, using good turfy

loam, with a little leaf-mould, some thoroughly rotten manure, and sand in proportion to the greater or less quantity which the loam naturally contains; but *Fuchsias* do not require the soil to be quite so open as some other quick-growing plants. Pot moderately firm; but not so much so as in the case of some things of a more permanent character; pinch out the points of the shoots to induce a close, well-furnished condition. Some varieties require less attention in this respect than others, being naturally disposed to branch out without stopping. A well-grown *Fuchsia* should, when in bloom, present a dense mass of pendent shoots drooping from a single stem, each clothed with healthy foliage and flowers. This state can be secured in these autumn-struck plants in a way that it is difficult to accomplish with old specimens or with later spring-struck stock, although the latter make nice small examples, but for large conservatories, where size is an object, autumn-struck plants are the best.

Camellias.—Where these have not, yet had their annual cleaning by sponging the leaves and removing any scale insects that may exist on the shoots, it should at once be attended to. In the neighbourhood of towns, where the atmosphere is charged with soot, they are greatly benefited by having their leaves sponged two or three times a year. If the plants are turned out in beds—and still more so when grown in pots or tubs in conservatories, where some warmth is kept up during the winter—special care must be taken that the atmosphere, as well as the soil, is not allowed to get dry, or the buds are sure to drop; this is particularly the case with the white varieties, which are more easily affected in this way than the others. Where any large plants of inferior kinds exist that it is intended to graft with better sorts, they may now be headed down and grafted. Many of the numerous ways in which grafting is performed will answer, but if the plants are large and the stems a considerable length before branching out, they may be cut down 3 inches or 10 inches above the collar and cleft grafted, putting in four or six, binding the stock round so as to keep the unions in their places, surrounding the whole with ordinary grafting clay, after which they may be placed in a house or pit where a little extra warmth is kept up. I have found *Camellias* succeed best when grafted thus early, before the sap is about to rise, as if the work is deferred too long the flow of sap is such as to often prevent the grafts taking.

Begonia Gloire de Seaux.—This is a most valuable plant for the stove, flowering as it does from early December right up to April, the foliage itself making it a conspicuous subject, but doubly so when laden with its pale pink blossoms, which push out at the axil of nearly every leaf. The plant also lends itself to discretion in the house, lasting in good condition for a fortnight or more. It attains 3 feet to 4 feet in height, and can be either grown on a single stem or pinched to form two or three shoots. Cuttings should be put in during April or May, and I find they emit roots very quickly if placed in a close frame or propagating-box with a gentle bottom-heat in a house or pit that commands a temperature of 60 degs. to 70 degs. Merely dibbling in the shoots in Cocoa-nut-fibre or sifted leaf-soil appears to suit the cuttings better than if placed in pots. As soon as rooted pot up into suitable size pots, and keep in the box for three or four days, when they soon get hold of the soil, and then can be placed near the glass roof in a house that does not fall below 60 degs. at night. Repot when necessary, using loam, leaf-soil, a little peat, and enough sand to keep the whole porous. Useful decorative stuff can be grown in 7-inch pots and quite large specimens in 6-inch or 7-inch. Keep the syringe from the plant when in flower, and avoid too much water at any time, as I have found plants go black in the stem quite close down to the pot just when coming into flower. This I attribute to the plant being kept too sodden at the root.—J. M. B.

As many of the most interesting notes and articles in "GARDENING" from the very beginning have come from its readers, we offer each week a copy of the latest edition of either "STOVE AND GREENHOUSE PLANTS," or "THE ENGLISH FLOWER GARDEN," to the reader of the most useful or interesting letter or short article published in the current week's issue, which will be marked thus "A."

THE POPPY ANEMONE.

It is needless to sing the praises of the Crown Anemone. Everybody who has any acquaintance with garden flowers knows its merits, its easy culture, fine bloom, and the variety of colour which a mixed collection affords. Those who planted in October will have abundance of bloom in spring, and there are few plants more serviceable for house decoration thus early in the year. A sowing of seed in June will produce plants which, set out in autumn, will flower the following spring; so that those who wish to grow them need not obtain named kinds, unless they have a partiality for any particular varieties.

CARNATIONS FOR SPRING PLANTING.

MANY amateurs prefer to buy what they require and plant out in spring; although they may be aware that the best results can be expected only from plants settled in their winter quarters in September or October, they do not like to run the risk of the winter, and there is something to be said in favour of this plan, as they can buy now strong, well-rooted plants and have

of the border, which it is as well to have trenched, two spits deep, some time before planting takes place. If, however, this is not practicable, or has been omitted, it should be done at once, and the soil trodden down before planting, or rolled all over, as it is an absolute necessity that the ground be in a firm condition before the plants are inserted. The most suitable soil is a good sound loam, neither too heavy nor too light; and, as to situation, experience leads me to select a border that is shaded from the hottest rays of the sun—during the middle of the day and during the afternoon—as, by this selection, the blooms last longer and do not require shading, which, if required for exhibition, they would otherwise do. Carnations should be grown in beds by themselves, and not mixed up with other flowers. The plants should be set out from 13 inches to 15 inches each way, according to the size of the plants, some being much stronger growers than others. They are also very effective if planted in clumps of any one colour—for this purpose the self-coloured varieties are to be preferred. What, for instance, could be more lovely than an entire bed of that exquisite new pink variety, John

plant, they will answer very well. Weak growers and some of the more delicate varieties of yellow-ground Picotees are better grown in pots, as they can then have the protection of cold-frames when required, and it is not judicious to plant out in the open border plants that have been grown in large pots and not provisionally potted up. The plants being set out, if the weather is exceptionally dry it may be as well to give them one good watering, unless rain may be shortly expected, and if the border is in a sunny position it should be mulched all over with well-rotted manure about the beginning of May. This has the double advantage of strengthening the roots and keeping them cool from the scorching rays of the sun. Weeds should be carefully gleaned off the bed as they appear. Beyond this, no further attention will be needed until the plants begin to grow, which will, perhaps, be the subject of another paper.

As your readers may like to have the names of varieties, both self and fancy, which can be relied upon to give first-class results, either for the home garden or for exhibition, I give below a few, which may, perhaps, be sufficient

The Poppy Anemones (*Anemone coronaria*). From a photograph by Mr. F. Mason Good.

them delivered to them on to me almost identical with those ordered for layers sent out in the autumn. As this end next month are the best for spring planting, those wishing to cultivate these lovely flowers, or improve their existing collection by adding new varieties thereto, should send their orders to reliable growers at once, who will supply them with lists from which to choose, or supply collections on reasonable terms if the selection is left to them. It is as well to bear in mind that it is just as cheap to grow a good Carnation as a bad one, and far more satisfactory in the long run; and, seeing the great improvement that has been made of late years in the form, colour, strength of stalk, and soundness of calyx of the best varieties, it is really wonderful to see such as were in vogue twenty years ago still being advertised, and presumably sold to somebody, when newer Carnations of the same colours, with the faults eradicated, can be purchased for almost as little money. I refer to such as Ruby Castle, Redraze, Mrs. Muir, and some few more, which have been expunged from all collections years ago that have any pretensions of being kept up-to-date. Supposing, therefore, that the amateur decides to buy his plants now, his first consideration must be the preparation

Corlett, edged with a broad band of dark blue Lobelia?

The above remarks concerning planting refer to Carnations grown from layers. If seedlings are to be grown, more room must be given, as they become much larger plants—2 feet each way would not be too much space to allow. In either case sufficient room must be given between the plants, or there will not be sufficient space to layer them in July and August.

It is as well to plant, where possible, on a slight slope, so as to secure good drainage, as Carnations require this and cannot stand being waterlogged. The roots should be well covered, but not too deeply, so that the foliage stands up well above the surface, and under all circumstances the plants should be firmly set out in their places, and the soil pressed well down round the roots. If plants are received in pots, care should be taken not to break the ball of earth, and to guard against this a sufficiently large hole should be made with the trowel, and the plant inserted therein with care before being pressed down. But if the plants sent in the spring are from layers that have stood out the winter in the open border, but have not during that time been covered from the parent

for moderate requirements. I have omitted yellow Picotees, as these are best grown in pots, and the above remarks are intended to apply to spring planting in the open border alone.

Self-coloured Carnations.—White: Mrs. Eric Hambro, Evangeline, Diamond, Silver Strand. Bright scarlet: Banner, Tommy Atkins, Grenadier, Pillar-box. Yellow: Duke of Orleans, Agnes Dunham, Buttercup. Pink: John Corlett, The Major, Minerva, Pilot. Deep red: Faust, Isinglass, Lady Hindlip, Mrs. ManRae. Orange: Mrs. Gray Buchanan, Grange Lord, Minnie, The Dyak. Salmon: Miss Beechie Keats. Crimson: Gipsy, Mephisto, Crook, Uncle Tom. Flash: Nantoh Girl, Iris Exile, Darling. Purple: Cleopatra, Purple Emperor, Bendigo. Heliotrope: Blue Danube, Sophia, Springfield, Oarville Gem. Cerise: Miss Elma Sheppard, Vyryan Williams, Gordon. Crushed Strawberry: Lord Simon, Windsor.

The following are good fancies.—Yellow grounds: Cowslip, Thomas Renwick, M.P., Yellow Hammer, Australian Gold, Mrs. Ashby Proud, Dragon, Gitana, Infants, Butterfly, Brodrik, Climax, Amber Witch. White grounds and white ground Picotees: Duchess of Portland, Dresden, D. W. Bain, Old China,

Lottie Collins, Meta, Isabel Lakin, Joseph's Coat, Duchess of York, Mrs. Oppenshaw, Somerhill, Fortrose. H. W. WARELIN.

EARLY BLOOMING WALLFLOWERS.

THESE sweet-scented flowers are universal favourites, and we now have kinds which will yield flowers from the end of October until the middle of May, provided the proper varieties are selected and the seed sown at the proper season. Time was when the old Harbinger was the earliest to flower, and by sowing early in the spring it was possible to have plants that would yield a good percentage of bloom in the following autumn and winter. Since then other varieties have been introduced which have superseded Harbinger, foremost of which is named Earliest of All. This is rightly named, for it is not only the earliest to flower, but it yields a longer succession of blossoms than any I am acquainted with. It is of dwarf habit than Harbinger, is very hardy, and every growth produces a spike of rich yellow, sweetly-scented flowers. From plants raised from seed in the beginning of July I have seen cutting an abundance of flowers for weeks past. The frosty weather produced a temporary cessation, it is true; but now that mild weather has again set in the plants are flowering as freely as ever. Harbinger forms a good succession to Earliest of All, and lasts well into the spring, when the majority commence to bloom. The early-flowering varieties should be sown not later than the middle of June, and the resulting plants pricked out where they are to bloom as soon as fit. Rather poor soil is better for Wallflowers than that which is rich, as they then make harder and more sturdily growth. A. W.

PERUVIAN LILY (ALSTREMERIAS).

MUCH has been written during the past few years concerning the culture of these handsome plants, some correspondents apparently experiencing considerable difficulty in growing them successfully. As far as my experience goes, however, I have found them (I write only of the hybrid *Alstemerias*, *A. chilensis* and the orange-flowered *A. aurantiaca*) of the easiest possible culture. They have with me thriven equally well in retentive, damp soil, which some writers declare is fatal to them, as in a light, shaly steppe. In the autumn of 1894 I planted some tubers of *A. chilensis* in a bed of heavy red loam in a low position close to water, at a depth of 3 inches, and did not mulch them. Early in 1895 commenced the memorable frost, which continued with scarcely any intermission for nearly three months. About that time I read an article on *Alstemerias* by an experienced French grower, in which it was asserted that the roots were certain to be killed by frost unless they were planted from 6 inches to 9 inches deep and heavily mulched. I naturally gave up my plants for lost, for the ground was frozen hard and nothing could be done. However, greatly to my surprise and delight, they pushed up strongly in the spring, not a single plant appearing any the worse for the winter's experience. These plants grew and multiplied exceedingly, and were divided again and again. The seed-pods were never picked off until the seed was almost ripe, but this did not impair their vigour. In another site, on a steep slope of very light soil that becomes dust-dry in summer, they are equally at home. Here they throw up their flower-scapes out of the adjacent path and through the interstices of a neighbouring flight of wooden steps. *Alstemerias aurantiaca* is a perfect weed, and quite overruns the garden, being extremely difficult to eradicate. Of the two the hybrid *Alstemerias* are far preferable, and present a lovely sight when in full flower, with their suave colour gradations ranging from crimson-maroon to cream. They will withstand the roughest treatment with equanimity. Last spring I lifted a clump when the growth was about 3 inches high, took them 20 miles, and planted them the next day in a steep, sloping bank of light soil. They very naturally died down, and gave no further sign of life that year. Now, however, they are shooting strongly, and their growth is this day (January 18) about an inch above the soil. Plants are easily raised from seed sown in pans as soon as ripe and kept in a cold-frame for the first winter. The lovely *A. pelegriana* and its white variety I have never seen doing really

well in the open border. I have tried them, but failed in heavy soil. I have now, however, got both varieties in pots, in which I hope to bloom them the first season, and then to plant them out without disturbing the roots in light soil in a warm position. S. W. F.

PROPAGATING VIOLETS.

THERE are various methods of propagating Violets, probably the most common being to take runners from plants that have flowered throughout the winter in frames, and to plant them in the open in April. These are sometimes pegged down in the soil in the frame to induce them to form roots previous to being detached from the parent plant. Another way of propagating them is by cuttings inserted in fine gritty and leafy soil in a frame or boxes in autumn. These, if protected by a frame during winter and kept moist, become nicely rooted by spring and are ready for transplanting early in April. A somewhat new and, to my mind, good way of propagating them consists in pegging down the required number of runners, which form on the plants when growing in the open border in summer. August is a good time for this operation, as then the runners are well rooted by October. At the end of the latter month they should be severed from the old plants, carefully lifted with a trowel, and potted in $3\frac{1}{2}$ inch pots, using loamy and leafy soil. Pottings completed, plunge the pots to the rim in ashes in a cold-frame, where, with liberal airing and careful watering, the plants will make fine specimens, and, if planted out early in April, will grow into dense clumps and produce a wealth of bloom the following winter. C.

BLUE LOBELIA.

THIS old favourite for edging flower-beds and borders is not likely to be superseded for some time, for when it is well done there are very few edging plants that can equal, much more excel, it. The principal cause of failure is in having small, weakly, or drawn-up plants to start with, owing to the too common plan of growing seedlings and not giving them enough time to develop into dwarf, bushy little tufts, as they should be when put out in May. I know many who do not sow their seed until after my stock has been divided and pricked off into pots or boxes. If I rely on seedlings, I sow in boxes in August and winter in cold pits or frames, and then there is any quantity of sturdy little plants fit for pricking off in January or February. I prefer plants that have been left over from bedding out, and that have been flowering in boxes, so as to be able to weed out any inferior ones. Do not let them get exhausted with flowering, but clip all the bloom off two or three times in the autumn, so that in October the boxes are dense masses of very dwarf, tufty plants. I find they make excellent companions to yellow *Calceolarias*, being quite as hardy, and delighting in a cool, moist temperature. If they can be kept from getting sootily frozen by means of mats and litter, it suits them far better than artificial heat, and where a good many bedding plants are required it is an advantage to have a good lot of plants that do not need the shelter of artificially heated houses. One or two boxes of plants kept through the winter in this way will make hundreds of plants when divided early in spring, and there is plenty of time between January and May to divide a second time, as they will fill the boxes in a month. To keep them dwarf, clip off any tops that start to flower.

Gaspert.

J. GROOM.

TUFTED PANSIES.

PREPARING FOR SPRING PLANTING.

TWO often those who grow Tufted Pansies (*Violas*) leave the preparation of their flower-beds and borders until far too late. An early preparation of the soil is essential to success. Pansies are voracious feeders, and the soil needs to be enriched by the addition of some good manure, and the ground deeply dug as well. Many are the queries addressed to GARDENING ILLUSTRATED during the flowering season, and particularly during the month of July, regarding the failure of plants at that period. Failure may not infrequently be attributed to the strain of plants one may be growing. The gaudy and striking colours as represented by many of the

continental kinds attract many cultivators, but unfortunately these plants have no constitution worth speaking of. The warm days of July are too much for them, and in consequence they wither and die. This cannot, however, be said of the Tufted Pansies. The only risk of failure with the tufted form of these plants is when they occupy the same position in the garden year after year. As a rule, the plants succeed remarkably well the first season, and give a prodigious display of their welcome blossoms. During the second season in the same ground the display is good, but here and there a plant may fail, and to some extent mar the general effect. A third year in the same position the gaps will be more frequent, plants falling without any apparent reason. Growers usually shift these plants to fresh quarters each season, and in this way guard against failure. However, this is not possible in many gardens. It is a difficulty which may be overcome by deeply digging the quarter of the garden devoted to these plants in the winter-time. At least two spits deep should the ground be dug, incorporating some thoroughly good manure at the time, and leaving the surface in a rough condition or else in ridges. As some six weeks to two months at least must elapse before the planting will begin in most gardens, this will leave ample time for the frost to get well into the soil, and in this way pulverise and sweeten it. A garden well tilled is the chief factor in successful culture. Ground treated in this way may be lightly forked over and levelled just prior to planting. This winter cultivation also rids the soil of insect pests to a very large degree. D. B. CRANE.

PROPAGATION OF THE DAHLIA.

IN large nurseries where Dahlias are propagated to a great extent, the work of propagation has to be commenced early in the year, and a low-pitched lean-to house, with a south or east aspect, is generally used for the purpose. This is heated by means of hot-water pipes passing along the house immediately underneath the propagating bed, which is raised near the glass. The roots are placed on the bed, and partially, but not entirely, covered with soil; this is kept fairly moist, and when a temperature of from 70 degs. to 80 degs. is maintained a number of young growths spring up round the crown, and of these cuttings are made. The propagating-house is generally at the end of a snug potting-shed, so that the tender outtings should not be brought into contact with cold currents of air, for the Dahlia is a plant of peculiarly tender growth, and is soon affected by cold. In addition, it is usual to have a series of brick pits sunk below the ground level, so that manure lying can be placed about them to heat the beds. These pits are indispensable, for it is found that the outting-house is required almost entirely for obtaining outtings, and striking these cuttings has to be done in the brick pits. In these pits a moist heat of about 60 degs. is required, and should be maintained as equally as possible.

MAKING THE CUTTINGS.—When the shoots are about 3 inches in length they are taken off close to the roots and inserted in pots containing light soil, and then placed in the brick pits plunged in fibre. When rooted the cuttings are potted singly into $2\frac{1}{2}$ inch pots, returned to the hot-bed, where they are kept close for a few days, and then follows a careful and gradual process of hardening off, so that by the middle or end of April they can occupy a cold-frame. The great thing is to keep the plants sturdy, dwarf, and stocky, and this can be secured only by constant care and attention. Amateur cultivators, who require but a few plants, can begin the work of propagation early in March, using for the purpose an ordinary hot-bed, in which the roots can be placed, and, resting on a bed of soil, be also covered with it, but not to hide the crown. When the shoots are about 4 inches long the roots may be divided with a sharp knife, leaving a piece adhering to each outting, and in this way good plants are formed after they have been potted and plunged in the hot-bed.

Too much heat or damp must be guarded against, and also, if there is a decline of heat, fresh manure must be added. In all stages of the work of propagation the peculiarly tender character of the Dahlia must be borne in mind, and the effects of cold guarded against.

INCARVILLEA DELAVAYI AND OTHERS.

New and again the introduction of some entirely new and altogether remarkable species of hardy plant opens out, as it were, a new vista of the

slightly notched. A peculiar odour escapes from the leafage when freshly handled. The root is also exceptional—a long, fleshy tap root, as it were, that in strong plants would have a diameter of 1 inch or more, and 12 inches in length. At the summit of this tapering root the growth-buds issue and die away just as completely when the flowering is over. The plant produces seeds in great quantity. A deep bed of earth is an essential when planting it by reason of the length of root, and the plant succeeds quite well in ordinary loamy soil. The illustration affords a good idea of a small plant of this. In very dry seasons a good watering is helpful to the later flower-buds. This fine plant is a native of Northern China.

The other species of the genus pale into insignificance somewhat, so far as is at present known. The best, however, are *I. Olga*, with bright rose-coloured flowers produced on a more leafy stem than the last-named. There is, however, somewhat of the same pinnate leaf character, but the segments differ in being oblong, narrow, and pinnatifid, whereas in *I. Delavayi* they are broader and more rounded at the tips. Height 3 feet. Native of Turkestan.

I. COMPACTA. — Flowers rose-pink. North-west China. I cannot speak of this from actual experience, and the plant may not be in cultivation at the present time.

I. GRANDIFLORA. — A novelty as yet not generally in commerce. The plant, however, is very distinct, and the flowers are said to be finer than the best forms of *I. Delavayi*, while the throat is white, slightly lined yellow. The

be said to be an improved form of the first-named.

I. VARIABILIS, with smaller rose-coloured flowers, is of hushy habit, and it is probably not strictly hardy. F. J.

PHIORMIUM TENAX IN OPEN AIR.

THE beautiful illustration (see page 667) of this noble Flax growing in Regent's Park, with the description of its adaptability for open-air gardening in the warmer parts of these islands, causes one to wonder how it is that such a very distinct foliage plant is not more common on the coast, for its tough leaves seem to single it out as well suited for a windy locality. Doubtless many are deterred from trying it in the open air by reason of having been accustomed to see it growing in glasshouses, more or less heated, and that it does grow luxuriantly in them no one can deny. But I feel sure that there are many places in England where these plants would prove quite hardy. Last year I had a good lot of seed sent me direct from Taranaki, New Zealand, and as the seedlings came up more abundantly than I required them for pot culture, I resolved to give them a chance in the open air, and, although we have had 15 degs. of frost on several nights in succession, they do not seem in the least affected by it. If young seedling plants will survive this trying ordeal, I should feel perfectly safe as to older and hardier-tissued plants safely standing any frost on the coast, for we have no shelter here from the cutting winds. In places where good thick shrubberies or belts of trees break the wind there are generally plenty of sheltered nooks where plants of doubtful hardiness can be placed, and anyone trying these plants might add a new feature to his permanent foliage plants by placing *Phiormium tenax* and some of the graceful *Bambusa* in groups where some overhanging branches would mitigate the severity of our climate and give them a very near approach to that of New Zealand. JAMES GROOM.

Osport.

CAMPANULA MIRABILIS.

THIS handsome species from the Caucasus, although only biennial in character, deserves a place in every collection. It is quite distinct in appearance from all other *Campanulas*, forming rosettes of large fleshy leaves, from which issue erect stems bearing lovely pale blue flowers, each from 2 inches to 3 inches across. Large, delightful in colour, and free flowering are among the chief attributes of this handsome plant, and all who can should save seeds of this

Incarvillea Delavayi.

probable riches in store for the future. The comparative slowness, however, of the coming of such things leads one to believe that the army of hardy plant collectors is but a small one, or they have fallen upon idle times or barren places. Of the striking novelties that come before one at such a time, *Primula roses*, *fiachera sanguinea*, *Hemerocallis aurantiaca* major, with the above-named, are the most conspicuous. Not that these represent the actual array of novelties, but rather a few of the striking ones that cannot be left out from any garden. And this is the kind of plant we would see more of. It is in circumstances such as these that the *Incarvillea* above named come as a welcome surprise, accompanied by the oft-expressed hope that it may prove quite hardy. This much was expected of it, judging from the district whence it came, and the plant has not only proved quite hardy in the open, but one of the best and most showy things that have been introduced for some time. The plant belongs to the order *Bignoniaceae*, which does not give us many hardy plants at all, and still fewer those of a distinctly herbaceous character. Therefore, this well-marked species of *Incarvillea* is not only a distinct gain to hardy plants, it is at the same time capable of creating a feature entirely new in any garden in which it may be freely planted. The blossoms individually most nearly represent the flowers of a type of *Gloxinas* of a past period—viz., the drooping type. This is seen in the slightly arching tube, in the broad expanse of the reflexed margin, and in other ways. Not only is the plant perfectly hardy, it is of easy culture, and quickly gains vigour. Fully grown, the inflorescence rises to fully 3 feet high, bearing a long profusion of the rose-carmine trumpet-shaped flowers on strong stems. The foliage is quite remarkable, too, and in its Fern-like outline extends to 2 feet in length, the leaflets on each side of the mid-rib oppositely placed and

distinct, and the flowers are said to be finer than the best forms of *I. Delavayi*, while the throat is white, slightly lined yellow. The

foliage is broader and shorter than *I. Delavayi*, and ascends the stem to some extent. The root is only slightly tuberous, which stamps it as a distinct plant at once. In other respects it may

A Caucasian Bellflower (*Campanula mirabilis*)

striking Bellflower, and, when fully ripe, sow at once. If kept for any time the chances are against the seed germinating. Sow the seeds on the surface without any covering of soil, and place over them a piece of slate or shaded glass to exclude the light. As soon as the seedlings appear gradually inure to the light, standing close up to the glass to prevent them becoming drawn. It must have liberal treatment from the first if justice is to be done to it, and it would seem to be well suited for grouping in the rock garden or for planting in the border in rich soil. The plants should be set out early in the year if possible, so that they may get strong before the winter arrives.

Selection of Sweet Peas.—The varieties named at page 610 are all good, embracing

most of the best. But I may be permitted to name one or two other really good and distinct kinds. As a highly coloured kind I have seen nothing to equal *coccinea*. It is a new shade of red, a brilliant corise self. It has bold, erect blooms. This is an exquisite flower for evening wear or for table decoration at night. When better known it will be extensively grown. I grow all the last year's new kinds, and out of them the Hon. Mrs. Kenyon, Miss Wilmot, George Gordon, and Lord Kenyon were the best. Stanley I consider one of the very best dark kinds, and Vanus is a charming salmon-buff, the standards a delicate shade of rosy-pink.—J. CROOK.

PHLOX DIVARICATA.

For many years I have been a subscriber to your valuable paper, *GARDENING ILLUSTRATED*, and have found in it some very useful information; but though I have been a constant reader, I have not, as far as I can remember, come across an article concerning a very nice little plant named *Phlox divaricata*, syn. *Phlox oenandensis*, which a friend induced me a few years ago to cultivate. I gave it a fair trial, and it has proved to be both pleasing to the eye and easy of culture, and it now ranks as one of my special spring favourites. Perhaps a few notes on this plant might be acceptable, and, if so, would you kindly insert the information given, and thus perhaps be the means of encouraging your readers to adopt this nice old-fashioned plant in their gardens? I think they would find it worth their while. This plant was introduced from North America in the year 1746, but underwent the fate of as many good plants that were discarded for the so-called novelties, which were soon judged. But sooner or later the time of neglect ceased; many amateurs (here in Belgium) cultivate it already, and I am certain that in a few years to come it will be found in all the gardens, because to see it is to adopt it. The *Phlox divaricata* is, without contradiction, one of the nicest amongst its species, which show their blue bloom in early spring. It is a perennial, with simple, whole, opposed leaves of a dark green. The plant is 10-12 inches high when in full bloom. It resists very well to a temperature of 5 degs. Fahrenheit—that is to say, to our coldest winters. It flowers at the same time as the Forget-me-not, and notwithstanding the latter's real qualities, the former could very advantageously replace it—if not quite, at any rate it might with great fitness procure a change in the making of spring beds.

Propagation is easily done, either by division or by cutting. The former is done immediately after flowering, about the end of June. Divide the plants in three to five divisions or more, according to their strength; cut the upper part to within six or seven leaves, then place these divisions in a nursery on a border enriched with mould to a distance of 6 inches all ways. Keep the soil always moist and free from weeds. These divisions will soon grow into nice plants ready for planting in the spring beds in October in preference to March, with a good ball of earth to the roots. Distance, about 10 inches apart. At the end of April or the beginning of May they will reach about their maximum development—that is to say, 10 inches to 12 inches. Then they cover themselves with an infinity of tender blue flowers of the same form as *Phlox dasycarpa*. These well erected flowers form a carpet so close that the leaves are completely hidden by the flowers, and nothing is so nice to the sight than a bed of these *Phloxes*. If the propagation is done by cuttings, lift some of the strongest plants, after flowering, with a ball of earth to the roots, plant them in a good soil in a corner of the garden, water when necessary, and leave them there until July or August. Then take all the cuttings possible, 1½ inches or 2 inches long, cut off the lower leaves, and insert them in a well-prepared soil, to which mould has been added, under a close frame in preference. Keep moist and shaded. A fortnight after they will have rooted; then keep the frame open night and day, and water well. When well established take off the frame, and treat the plants like those propagated by division. July and August are the best months for doing this propagation, although the cuttings will strike at any time in the year. If done in February or March, the propagation by cuttings

must be done in a cold greenhouse of 40 degs. to 45 degs. Fah.; therefore, lift some plants in September, put them in pots, and keep them in the greenhouse, as that the plants may be in vegetation at that moment. But by this way the plants will be much inferior to those propagated in July or August.

The *Phlox divaricata* thrives in any soil, but prefers one on the light side and substantial, but can also grow in very wet soils if, instead of planting direct in the bed in October, it is planted on an elevated bed under a frame and left there until the end of March—the time when to plant in the beds. The frames are always left open, but covered over to keep the rains and snow off. For permanent borders this plant is also very useful. In this case renew the borders every two or three years by division. I hope that this plant will find as much favour in England as it has in Belgium.

Antwerp,

A. V. BAINES.

TUFTED PANSIES (VIOLAS) FROM SEED.

THERE is very good reason for believing that many gardeners regard these showy hardy plants as somewhat difficult to raise from seed. As a matter of fact, they are as easy to raise as are many of our best annuals, and may be treated somewhat similarly. For some reason or other, those interested in the *Viola* have often deferred commencing operations until the spring is well advanced. It has been my custom for years to sow a pinch of seed in the closing days of January, the temperature of the glass structure in which the pan of seed has been placed being maintained at about 45 degs. to 50 degs. Already the first lot of seedlings are pricked off and are just now developing the third leaf. They may or they may not be pricked off again later, but the chances are that before the end of March they will be planted thickly in a cold frame, and subsequently planted in their flowering quarters towards the end of April, and possibly earlier. By adopting this method of procedure these seedling plants should be blossoming freely during June and July. One season, some years ago, I was able to make up a spray of six lovely blooms from seedling plants in July, and the plants had been raised from a January sowing, so far as my memory serves me. These facts, surely, are sufficient to prove what an accommodating plant the Tufted Pansy (*Viola*) is, and as there is good reason for doubting whether there is a hardier and more profuse blossoming plant in the hardy flower garden, which also combines with these excellent qualities such a continuity of flowering, the points of merit are so overwhelming that no one who desires something really beautiful in their garden to look upon for months should hesitate longer before commencing operations.

Good seed is the all-important consideration in beginning, and that one may anticipate a successful issue, procure seed only from those who make a speciality of these flowers. Seed may now be purchased which has been saved from certain distinct sorts of proved merit, and in this way flowers of white, yellow, blue, and other colours may, to a large extent, be ensured in the resulting seedlings. Yet, for general purposes, a small packet of mixed seed—and this can be purchased for a shilling or half-a-crown—will be better. Procure the seed as early as possible, and make a sowing without delay. Pots, pans, or shallow boxes may be requisitioned for the purpose, and for choice the latter receptacles have advantage. Slightly crock the boxes and cover the crocks with some of the rougher portions of the soil. Pass through a sieve with a rather fine mesh equal quantities of leaf mould and loam, adding thereto a liberal quantity of silver-sand, sufficient, in fact, to make the compost porous. Mix thoroughly, and afterwards fill to edge of the boxes with the prepared soil. Sow thinly and evenly over the surface of the soil in the boxes, just covering the seed lightly with some fine compost. A slight pressure on the surface soil is all that will be required, and then the warmest quarter of the greenhouse should be chosen in which to place the boxes. When the soil shows signs of drying hold the boxes in a large vessel of water, allowing the latter to percolate up through the holes in the bottom of

the boxes, and as on through the soil. In this way one may be quickly satisfied that the soil is thoroughly moistened. An occasional dewing overhead with slightly tepid water from a fine-sprayed can is very helpful when the seedlings are appearing. Subsequently prick off each one in similar boxes of slightly heavier soil, spacing them out about an inch or rather more apart, and the same distance between the rows. When the genial weather of spring is with us place the boxes of seedlings in cold frames, planting them outdoors subsequently when properly hardened off. This is a most fascinating occupation, as one may raise something so much better than existing kinds.

D. B. CRANE.

FLOWER-BEDS.

(REPLY TO N. REGGLES BRISK.)

You would have helped us in this matter by giving the size and extent of the beds and their environment. So much depends on such circumstances. A set of small beds arranged in a formal way may be best set out with the usual summer bedding things, as being too small for much display of flowering subjects. In the absence of any such particulars we can only vaguely suggest. Corner beds, for example, are well suited to *Heliotrope* pegged down, and another set to *Verbenas* similarly treated. Smaller beds on the inside of those just named may be planted now with pale mauve and yellow shades of Tufted Pansies, for which the ground must be well prepared. Plant these quite thinly, and employ exclusively rooted cuttings as opposed to mere divisions. Later on, say in May, these beds may be filled up with *Tuberous Begonias* to take the place of the first when cut down in September. These spring cuttings of Tufted Pansies will start flowering in June and keep on right through August and often later; indeed, they make splendid beds alone. *Tuberous Begonias*, of course, may be freely employed in colours, and may be planted in April in the soil of the beds or started in frames. *Petunias* make a fine show in the open, and not less so the *Gazania*, which requires a sunny place. *Fuchsias* are also good, while the free-flowering Ivy-leaved *Persegoniums* are as good as most things. Much depends on what at present exists and whether you prefer such as the above to the usual so-called carpet bedding things, which, however, require almost daily care to keep them within bounds. The best things for the herbaceous border would be *Asters* in variety, particularly those of the *Comet* and *Triumph* section, which grow freely and give large, handsome flowers. *Stocks*, too, are very good for the same period, and such things as *Helichrysum*, *Love-lies-bleeding*, *Zinnias*, *Margaret Carnations*, etc. It is possible you may have room for some late-sown Sweet Peas. Your chief difficulty is that the position appears fully occupied up to July, when it would be late for transferring much of what we have named, unless it were possible to occupy part position quite near. We think, however, if the gaps referred to are large and occasioned by a superabundance of the *Poppies*, that these may be reduced another time and more permanent things inserted instead. At the time named there is a host of good things, but it is quite necessary to have them duly prepared elsewhere and of good size by July. Could you, in a reserve place, grow a series of early-flowering *Chrysanthemums*, and lift them bodily to the required position as early as possible, soaking well with water a day before lifting, and likewise when replanted? If so, no plant of our acquaintance will better endure the shift and more quickly recover or give a more varied display of flowers later on.

E. J.

Photographs of Gardens, Plants, or Trees.—We offer each week a copy of the latest edition of the "English Flower Garden" for the best photograph of a garden or any of its contents, indoors or outdoors, sent to us in any one week. Second prize Half a Guinea.

The Prize Winners this week are: 1, Mr. Geo. E. Lows, Dublin, for *Cuscuta reflexa* in Trinity College Botanic Gardens, Dublin; 2, Mr. E. Banbury, 80, Cadogan Square, W., for *Hedera ornariensis aureo-maculata* in a Norfolk garden.

ROOM AND WINDOW.

IRIS RETICULATA.

This Iris is a beautiful pot plant. Its sweet-scented flowers repay the closest examination, and when well grown it is an ornament to any greenhouse. In the open air its flowers appear naturally as early as February, so that little heat is needed in order to obtain bloom during the winter when the shelter of a greenhouse is afforded. Our illustration shows how, by growing a few bulbs around the sides of the pot, a very satisfactory effect may be obtained. It would look charming as a table specimen.

NOTES AND REPLIES.

Geraniums in window-boxes.—We have lately had a severe spell of winter weather, the thermometer registering from 15 degs. to 20 degs. of frost on the Grass for several nights in succession, and I must own that I was surprised to see some window-boxes filled with Geraniums of several kinds looking quite healthy at some almshouses close by Gosport. On inquiry, I found it was no new thing for the old folks living in them to keep their plants for years without renewal by the following very simple means. The position faces full south, and even at this early date, as soon as the sun shines out, the windows get quite warm, and as the boxes are set well into the sill of the windows they get a little warmth from the glass of the dwelling-room and any chinks in the casement. But the main protector was a good thick roll of sacking, nailed firmly along under the window-sill, during the day rolled up tightly, but at night brought up and fastened securely so as to cover the plants entirely. Certainly this very primitive mode of protection had answered its purpose well, for the plants looked far healthier than many I had lately seen in glass-houses heated with hot-water-pipes. It goes to show what can be done by those who really love their flowers, and do not mind what trouble they take to preserve them. I may add that in other windows bulbs were made a speciality. Roman Hyacinths were in full bloom, and Dutch bulbs of many kinds coming on rapidly, while the little plots in front of these cottages are filled to overflowing with old-fashioned Cabbage, Moolthy, and Mee's Roses, bulbs, and herbaceous plants. Owing to their sheltered sunny aspect, it is very rarely that one does not find something in flower, even in winter.—JAMES GROOM, Gosport.

Kentias.—Since these have become so widely grown they have to a very large extent supplanted the older *Latania borbonica* and *Scaevola elegans*. *Kentia Belmoreana* and *K. Fosteriana* are now grown by the million. Very few Palms are so well suited to indoor decoration as these, for large heads of handsome foliage may be kept in good condition for a length of time in very small pots. The great thing to keep them in good health is careful watering, so that they never get dry at the bottom of the pots, as all the best roots make their way into the drainage. I find it an excellent plan to put a good handful of bone-meal over the crocks, as the roots find it very quickly, and to support a large head of foliage the roots must have good food. I find that if artificial fertilizers are applied to plants in pots crowded with roots the plants continue in better health than if shifted into too large pots. I often have plants brought by their owners to me to tell them what ails them, and, as a rule, they are either dust dry, or else have been over-potted, and are soddened with water.

ROSES.

PRUNING ROSES.

The amateur Rose-grower who finds his Rose bushes pushing out green leaves at the tips of last year's wood thinks he is getting all behind if he does not start pruning, but the old practitioner has more patience, and lets these premature growths carry off the sap that is excited by a few mild days, and waits until March is well advanced before he cuts back to the buds he expects to get his crop of bloom from. Then, as we usually get cold winds and slight frosts at night, it is some time before these firm buds get pushed out enough to take any harm from frost, and more genial weather may be reasonably expected after April is past. But in addition to pruning too soon, the majority of amateurs do not prune hard enough to get fine blooms, for they leave too much

Early Balbous Iris (*I. reticulata*) in a pot at Kew.

of the small weakly wood that is not strong enough to bring blooms, and fills the centre of the bush with weakly spray-like growths. Far better results would follow if they first of all cut away all dead and very small wood, and then shortened the strong shoots to a few really good buds, for it is surprising how few good strong shoots make a fine head of bloom. And if really large blooms are desired, the Rose must be disbudded similar to Chrysanthemums, for many kinds of Roses produce far more buds than they can bring to perfection, and then they only rob each other, so that none of them can attain full size. The disbudding should be done as soon as it is possible to see which are the best buds to retain, and having done this, proceed to apply liquid-manure freely to the roots, for the Rose needs liberal feeding if size, colour, and perfume are to be of the best, and fine healthy foliage denotes perfect health and good culture.

J. O., Gosport.

NOTES AND REPLIES.

Rose Aimee Vibert.—The illustration and information given at page 637 should do much to induce many to plant this good old kind. It is to be regretted that several others of this class are not seen so frequently as they were thirty years ago. I quite agree as to its making a fine standard. Twenty-five to thirty years ago this kind was grown largely in a large Norfolk garden in this form, and never failed to give good results. While some of the Hybrid Perpetuals often were killed grown as standards, this kind did not suffer. I have seen great specimens as standards in a Somerset garden, standing on the turf, the shoots reaching the ground.—J. CROOK.

Moving Tea-Rose cuttings.—When the gardener cut down the Tea-Rose last August I made him put the pieces in a trench in the border. A great many of them started, and looked rooted. When would it be safe to remove them to the place I wish them to grow permanently, as I require the piece of ground they are now in about April?—DAVID.

[It is a great pity you must decide move the cuttings this year, but as you require in April the piece of ground they now occupy, we should advise you to transplant them early in that month. The soil is by that time in a more congenial condition for the fine roots than would be the case at present. You must be very careful to avoid breaking the tiny roots, as they are extremely brittle in this early stage of growth. If possible let some soil remain attached to the roots, even though two or three cuttings are close together. A good watering a day before removing should help you to do this. A little fine gritty soil given to each cutting when transplanting is of great assistance, and should be pressed firmly about the cutting. If you have such a thing as a frame on a bed of leaves where a gentle heat can be maintained, the cuttings could be potted next month into small 60 pots and plunged in Cocoa-nut-fibre refuse in such a frame. Some of the cuttings may only have the white wart-like substance at base, which is termed "callus," and from which roots eventually appear. This gentle bottom-heat would be of great assistance to them. A slight syringing over each fine day would be of much help to the plants, but water at the roots must be very carefully applied, and when it is given it should be made lukewarm. The plants could be planted out from the pots in May or June.]

CHRYSANTHEMUMS.

CHRYSANTHEMUMS FOR BEGINNERS.

Each season's display invariably has the effect of inducing a goodly number of persons to take up the cultivation of the "Golden Flower." The large, handsome blooms met with in private displays, and those also seen at the numerous exhibitions held throughout the country, create in the minds of would-be growers a desire to excel, and this frequently results in the same individuals becoming quite infatuated. Thus it is that in the early days of the new year requests are often made for a selection of suitable sorts for exhibition, etc., but this is hardly what the embryo exhibitor should desire. A beginner in the cultivation of the Chrysanthemum would derive far more satisfaction if he were to take in hand a given number of sorts of easy culture. Many of the best exhibition varieties are plants somewhat difficult to grow, and often require superior skill to bring the blooms to perfection within a given period. It is, therefore, very pleasing to note that there is a goodly list of excellent sorts which the most inexperienced may grow successfully, provided that ordinary care be observed throughout the growing season, and the hints, given from time to time in the columns of GARDENING ILLUSTRATED, be followed. While gaining experience in the cultivation of the easily-grown sorts, the ambitious grower is qualifying for the succeeding year's work, and in this way will be able, with confidence, to take in hand the more difficult sorts at a later period. Among the more reliable of those suitable owing to their ease of culture, the members of the Vivand Morel family of plants are the better known. Vivand Morel is a pretty silvery-mauve pink flower of drooping form, and attains to large dimensions. There are several sports from this variety: two of the better varieties being Charles Davis, a pleasing honey-yellow, and Lady Hanham, a

corise colour on a chamois ground. Either "crown" or terminal-buds may be selected, although those buds known as second "crown" are regarded with more favour. The plants are rather dwarf and fairly sturdy. A good bloom of incurved-Japanese form is Mrs. S. de Prohin, the colour being a clear pink with a silvery reverse. In this instance a first "crown-bud" is desirable, the plant attaining a height of about 4 feet. An incurved-Japanese of the purest snow-white is Western King. I have seen beautiful plants carrying six to eight large and handsome blooms, and they were grown with comparative ease. These flowers develop well and evenly from any bud selection, and the plant reaches a height of between 4 feet and 5 feet. Few Japanese blooms are better than those of Mrs. Coombes, this being a deep rosy-flesh-pink colour and of drooping form. Quite a goodly number of flowers may be developed on any fairly well-grown plant, and the height of the latter rarely exceeds 4 feet from a second "crown"-bud selection. Lionel Humphrey, although not one of the most vigorous plants, is robust enough for most purposes, and each bloom, which is of pleasing, drooping form, is borne on a good stout foot-stalk. The blooms are valued for their colour, this being a rich chestnut-crimson. Second "crown"-buds should be retained, in which case the plant attains a height of about 5 feet. The dwarf plants of Mrs. A. H. Hall are always valued by beginners, because the blooms come good from any buds, and they are also of splendid size and substance. The colour may be described as a shade of light brozza. John Bridgman is a plant of the easiest culture, and quite a number of beautiful blooms of goodly size can be borne by most plants without the least inconvenience. It is a robust plant, about 5 feet high, and the colour of the blossoms is a soft rosy-pink; second crown-buds should be selected. A superb white sort is Miss Alice Byron, and there is considerable doubt whether there is any better "all round" variety in commerce. The blooms are of incurved-Japanese form of the most chaste description, and they are of the purest white. The blooms come satisfactorily from any bud selection, and particularly so from cuttings inserted in April and flowered on single stems in 6-inch pots. A strikingly handsome flower is that of Miss Evelyn Douglas, an English-raised seedling, as are several of those already reviewed. The blooms of this variety are full and of pleasing drooping form, the colour being a lovely rosy-mauve, with silvery reverse. The habit is good. Late-struck plants flowered on single stems in 6-inch pots are a great success. Another bloom of exceptionally large proportion is Mrs. Barkley. The petals are long, very broad, and of leathery substance, and the blooms are seen in good form and condition from any bud selection. Colour, rosy-mauve, with silvery reverse; height about 4 feet when well grown. A capital chrome-yellow flower of pleasing form and good substance is Mr. Louis Remy. This plant is a member of the well-known family of plants of which Mrs. C. Harman Payne is the original. The blooms should be produced from buds selected during the latter part of August, in which case the result is all that one could desire. A pretty canary-yellow Japanese of drooping form is Soleil d'Octobre, and this has recently given us a very beautiful bronzy-fawn sport, which is to be distributed in the ensuing spring under the name of Bronze Soleil d'Octobre. Second crown-buds should be retained, and these develop evenly and kindly, and make large blooms. They are plants which any novice could grow quite easily, and their habit of growth is beautiful. In 6-inch pots on single stems the plants succeed remarkably well. E. O.

United Horticultural Benefit and Provident Society.—The monthly meeting of this society was held on Monday, Feb. 10, at the Caledonian Hotel. Mr. C. H. Curtis presided. Twelve new members were elected. A member having allowed his subscriptions to fall in arrear over twelve months wished to be

reinstated, but the committee decided that Rule 14 must be adhered to; they, however, re-elected him as a new member. The death of Mr. James Clarke, of Taunton, was reported, and a cheque was drawn in favour of the widow for the amount standing to the late member's credit in the ledger—viz., £61 18s. 2d. A member having received his full amount of sick pay, was granted 5s. per week from the Benevolent Fund. The widow of a lapsed member applied for the amount standing to the credit of her late husband, but there being a discrepancy in the accounts, the secretary was asked to make enquiries respecting the same. Ten members were reported on the sick fund, the amount paid out being £18 2s. for the month. The Treasurer reported a balance in hand of £743 16s. 1d., and was empowered to invest £650 in the best available Trustee Stock. The annual meeting will be held at the Caledonian Hotel, Adelphi-terrace, Strand, W.C., on Monday, March 10th, at 8 p.m.

TREES AND SHRUBS.

JAPANESE WINEBERRY (RUBUS PHENICOLASIS).

This handsome plant was introduced into England some years ago, and, as it is not only ornamental, but valuable for its fruit, there is no doubt that in the future it will be largely grown. Belonging to the same family as the

Japanese Wineberry (*Rubus phenicolasius*).

Raspberry and the Blackberry (*Rosaceae*), it resembles both of these, but the fruit, instead of being crimson or black, is of the clear, transparent tint of sherry, and has a fine flavour, with an agreeable acidity and sweetness combined. I procured seeds from America and sowed them in slight warmth in April. The seedlings, when large enough to handle, were potted off singly, and soon outgrew their pots. They were then transferred to the warm, sheltered corner, facing south-west, of a Devonshire garden, in front of a half wild hedge of brake fern, growing over granite boulders, giving them light but rich soil, in which they flourished well, throwing out fine suckers from 5 feet to 7 feet in length. These, during the autumn, were wired back to strong stakes, much as though they were Raspberries. Even without fruit, their splendid silver-lined foliage and deep crimson stems are decorative, but every spray has borne masses of the scarlet fruit (changing to wine colour as it ripens), giving a really fine effect of colour, as well as a quantity of delicious fruit. This *Rubus* is evidently perfectly hardy, although it is possible that the fruit may need a warm position to ripen it satisfactorily. It bears fruit, like others of its family, on the wood of last season, which should be carefully preserved, the older wood (which has borne fruit) being cut away after the fruit is ripe (as in the cultivation of Raspberries), the soil surrounding the plants being well mulched with manure. The flower is small and insignificant, making but very little show when in bloom; but it is quickly followed by rich madder-brown sprays of hairy fruit coverings, which might easily be mistaken for buds. Each of these, however, opens to expose the half-ripe scarlet

berry, holding it until it has expanded into the ripe fruit, which then drops to the ground. Seeds grow without difficulty if collected from the ripe fruit and sown on a hot-bed in spring. Ripening as it does in the middle of August, the Wineberry will prove a valuable addition to our household fruits, for it makes delicious preserves and tarts as well as being useful for dessert. Grown under a south wall, or in any position in which it will obtain the full force of the sunshine, much on the same lines as the Raspberry, no difficulty will be found in its cultivation. R.

FRUIT.

CORDON-TRAINED PEARS.

ANY grower, whether he be a professional gardener, amateur, or otherwise, may be justly proud of a well-grown espalier tree, and one sometimes meets with instances of successful culture of Pear-trees on cottage, villa, and garden walls. I was recently told of a wall-trained Pear-tree whose branches extended right and left to a distance of nearly 100 feet. More and better quality fruit may reasonably be expected from younger trees covering the same amount of space. A slightly greater length of wall was recently noted that had been planted about five years since with cordon Pears, two and three trees of a sort. In this short time the wall had become filled from top to bottom with healthy fruiting growth, and the fruit, as regards size and quality, from trees recently planted was excellent. Had I a vacant wall to furnish with Pears I certainly should plant cordon trees. True, the initial cost is somewhat greater than for these espalier-trained, because it is possible to plant a dozen cordons in the same space as one would allow an espalier-tree. The additional cost, however, would yield a quicker profit, and thus the initial expense would prove a useful investment. There are the means of reducing the expense at planting time by adopting the double or treble cordons, which would render a less number of trees necessary. A distance of 18 inches between each tree is not too much for single cordons, for double cordons, of course, allow a little more. Trees may be bought already trained into shape, and usually for cordon training they are worked on the Quinos. All do not succeed on this stock, but are double grafted to accelerate a fruitful or a more uniform growth. It is only certain kinds that need this treatment, and naturally these, by the extra care and attention expended upon them, are higher priced accordingly. (Glen Morceau is one that does better on the Pear than Quince-stock; Louise Bonne of Jersey, on the other hand, froites so freely that the growth becomes stunted in course of time, unless well supported by watering and feeding in summer.

Maiden trees are those often chosen by gardeners for treating as cordons. These, when cut down to within a few inches of the union with the stock, may be trained either singly or in twin fashion as growth advances. The value of these cordon trees when in their best form lies in the quantity of extra fine fruit that is given from a limited area and in a short space of time. They are usually trained in a slanting or oblique fashion, as this tends to suppress an undue rush of sap and vigorous tendency. If it can be done, a border composed of new turf eil sets up a quicker and more lasting fruiting growth. This a yard or so in width and about 18 inches to 2 feet deep will suffice for a long time. If this is too costly, a very good substitute may be had in deep trenching, incorporating with the soil something of a stimulating and lasting nature. Burnt clay is beneficial to fruit-trees of any kind. Soil that is poor may have a fairly good dressing of this, a little leaf-mould, and also some short manure. Bones not too finely ground, too, might be added, and soot is by no means to be despised. If the soil is naturally heavy see that some drainage is provided. Copious supplies of water in dry weather are necessary, and thinning of the fruit should be carried out in early summer. With rational treatment it is by no means rare for Pears to be grown to over 2 lb. each in weight. W.

Pear Bergamote d'Esperen.—This Pear bears freely whether grafted as a pyramid, bush, or cordon, and it is owing to its fertility

that finer fruits are not more often seen. Setting, as it does, so freely, thinning should be done with no nneparing hand. The fruits will then not only grow larger, but the quality will be considerably enhanced by such a proceeding. When the trees are allowed to carry all the fruit that sets, it must of necessity be small when mature, and there is little or no favour in the produce.

APPLE COX'S ORANGE PIPPIN.

ON the great merits of this Apple there is little need to enlarge, for the simple reason that it is one of the most popular varieties in cultivation—in fact it may be said to be the best priced dessert variety that exists. What also is most satisfactory, it fully deserves all that has ever been written in its favour, and if all we hear and read of it is true, the time is not far distant when this excellent Apple will be plentiful in the markets throughout the late autumn and winter months. Partial failures will happen with this as well as any other variety of Apple, but a complete failure I have never known—at any rate where one or two trees are not solely depended upon. I have five good-sized trees growing in different parts of the garden, thin-

training suits my purpose better than any other, but it does not follow that it is the best under all conditions. On the contrary, the variety succeeds admirably on dwarfing stocks, and grown either as a bush or cordon, or horizontally trained, and on a variety of soils. Very good fruit is sometimes obtained from orchard trees, but much the best samples are gathered from those more highly cultivated, which also are less liable to be disfigured by gales of wind. Not only is Cox's Orange Pippin of excellent quality, or second to none in this respect, its appearance also being greatly in its favour, but it possesses the great merit of remaining in season from November to March inclusive. It is the favorite exhibition variety, especially for showing in single classes, none but the very best samples of Ribston Pippin standing any chance against it. The variety was raised by Mr. Cox at Colnbrook Lawn, Slough, Bucks, somewhere about the year 1830, and is said to owe its parentage to Ribston Pippin. W. I.

BUSH APPLES FOR SMALL GARDENS.

TREES of this form have much to recommend them for small gardens. I prefer them in this form to pyramids. It is astonishing how small

may be planted in corners of borders, planting spring-flowering bulbs under. In summer, when the trees are in fruit, the bulbs are at rest, and the trees can be assisted with artificial manure or liquid manure. Failing either of these positions, then a few may be planted at the outside of the lawn or in the shrub border. In either of these places they are highly ornamental, both when in flower and fruit. Last year I saw in a small garden at a seaside place a small portion on one side of the lawn devoted to three small Apple-trees, with Tritomas, Pampas Grass, and a few flowering shrubs that would bear pruning, all associated together. Amongst these were bulbs to bloom in spring. The Grass was mown occasionally. When I saw them the Apples were laden with good fruit, of good size and colour. When at Bicton, East Devon, in October I was more than ever impressed with the value of these small bush-trees. On a piece of land just outside the wall many were growing in this form. These were planted a good distance apart, the ground being cropped with vegetables between. Many of these were only 4 feet high, and had eight branches to each. They had been planted three years, and cost 1s. 3d. each at the time of planting. Many of these small trees had a peck or more on a tree, and when this is put into figures at 4d. per lb. (14 lb. to the peck), it will be seen that this is a paying way to grow fruit. Most of the kinds here grown could have been sold at such a price in any good market. Beside these were trees of larger growth, having been planted longer. All were equally well cropped. I could not help noticing the fine clean appearance of the wood and the splendid colour of the fruit, as on the red sandstone the fruit colours magnificently. This is seen by the brightly coloured fruit shown from Sidmouth in London and elsewhere every year. This type of tree should be worked on the broad-leaved Paradise-stock, and should a tree be prone to grow strongly, then lift it in early autumn.

J. CROOK.

KEEPING APPLES.

THE excessive moisture we have experienced of late has been a source of much trouble where the fruit-room is not properly constructed, as there has been much difficulty in expelling the damp. To keep fruit plump as long as possible, the house in which it is stored ought to be kept as cool as possible without actually admitting frost; at the same time if the atmosphere becomes over-charged with moisture, and this cannot be expelled, decay sets in. All fruit-rooms should be ventilated at the apex in such a manner that when the ventilators are open the rain will be excluded and a circulation of air allowed to pass through without materially altering the temperature of the place. On dry days they should be opened for an hour or two, but should be closed again before the outside air gets too cold. Look over all fruit and remove that which may be starting to decay, as such soon spoils any that come into contact with it. Where Apples have been heaped together owing to want of room, these should be spread out thinly that they may be looked over occasionally without handling too much. Should severe frost visit us, be well prepared with material to prevent it from entering the store-room. All windows should be provided with shutters to open inwards, and the outside should be covered with mats in severe weather. It is not well to use fire-heat if it can be avoided, as this extracts too much juice from the fruit, and when applied to any extent causes the late kinds to shrivel long before they ought to. There are many kinds that will keep in good condition for a long time after they are ripe, provided the temperature of the store-room is kept low and at an even degree.

Fruiting branch of Apple Cox's Orange Pippin.

cropped being produced by the majority. All flowered well in spite, too, of bearing freely during the two preceding seasons, but the buds are not sufficiently self-protecting, and the fructifying parts of the flowers suffered from frost accordingly. That is the one weakness of Cox's Orange Pippin, but, luckily, it is not always that the trees are subjected to severe tests in this way. According to my own experience, particularly good pyramids are not easily grown, the habit of the tree being somewhat straggling, and I hold that the most profitable trees are those on the Crab stock and grown either as large bushes or half-standards. Very good trees can quickly be had by simply rotting out the leader of a pyramid as received from a nursery, the side branches being shortened back at each winter pruning till enough shoots are obtained to make a well-furnished tree, after which thinning out and fore-shortening are all the pruning necessary or advisable. In some cases it is useful to stake up some of the principal branches, or otherwise the heavy crops they produce will weigh them down to the ground. The illustration accompanying these notes was from a photograph of part of a branch of a freely grown tree framed out in the manner just described, and the fruit on such branches being well exposed colours beautifully. This plan of

bush trees can be kept in good health and fruitful. In December I had from a nursery some in this form not more than 3 feet high, with a mat of fibrous roots and full of bloom buds. These were planted at once, and no doubt they will bear enough to prove if the variety is true to name. When unpacking these I could not help noticing how much more fruitful some kinds were than others. Seaton House, Domino, and Laue's Prince Albert were literally covered with fruit buds. When such free cropping kinds are chosen there is no difficulty in keeping them to 4 feet high if it is wished, as their continual bearing prevents them growing too strongly. Trees of this size may be planted in many positions where those of larger size would not be suitable. In town or small gardens amateurs would find much pleasure and profit in growing, say, two or three dozen of such trees, and this may be done in many ways. I should prefer planting them in a quarter together 4 feet each way, as then they could be all treated alike and the ground not dug between them. Clumps of Daffodils may be grown between them, as when the leaves were off the trees in autumn the surface can be cleaned, adding a dressing of manure, this helping both the bulbs and trees. The Daffodils would be found most useful to cut from. If space cannot be found in this way, then they

"Farm and Home Year Book."—We are glad to be able to state that the "Farm and Home Year Book" seems to have met a warm felt by our readers. Its reception by the Press generally has been most cordial, and the demand for it has been so great that a third edition has been issued. Our readers should have no difficulty in obtaining it from any local bookseller or newsagent, who will order it if it is not in stock; or they may get it direct from the Publisher, 170 Southampton Street, Strand, by post, for 1s. 3d.

GARDEN PESTS AND FRIENDS.

Growths on Larch (*H. J. M.*).—The excrescences on your Larches are similar to those that are so common on the Beech. They are simply woody nodules, which protrude from the stems of old trees. They are said by Mr. H. Marshall Ward to be caused by the slow growth of the innermost layer of the bark (the cambium) of a dormant bud, the base of which separated at an early date from the wood beneath, the cambium then closed in over the base, and laid on thickening rings all round the axis of the bud, except at the extreme apex. When the separation occurred the cambium of the wood beneath covered over the previous point of junction, and thus the woody bud was pushed out with the bark, and now protrudes covered with a thin layer of bark. These growths are no detriment to the trees in any way.—G. S. S.

Wireworm in soil (*Ignoramus*).—Are you quite sure that the field of your tenant is infested with wireworms? I should imagine from your account of it that it was some other pest that had injured the crops. Could you not send up some specimens? I could then advise you better. However, supposing the pests are true wireworms, beyond good cultivation there is not much to be done as regards destroying this pest. Various insecticides will kill them, but their cost and that of applying them render them useless for field work. A perfectly clean fallow for some months, so that there are no weeds for them to feed on, with a good dressing of gas-lime, is as good a means as any for destroying them. If it should not be advisable to use gas-lime, keep the soil well stirred, so that the birds may have a chance of getting at them. These insects are very fond of Rape-cake, which should be broken up into small pieces (even the dust of the cake is useful) and sown over the land that is bearing an infested crop at the rate of from 5 cwt. to 7 cwt. per acre. The wireworms will be attracted from the crop by the cake. A dressing of nitrate of soda or sulphate of ammonia when the crop is found to flag is very useful in stimulating it into active growth.—G. S. S.

BIRDS.

Canary losing its feathers (*Pericivell Maxwell*).—Loss of feathers often arises from an irritable condition of the skin, caused by the bird being kept in an overheated atmosphere, or from its having been allowed to partake too freely of sweet oaks, sugar, or egg food, which produces a gross condition of the system. It may also proceed from general debility, or through the lack of some of the elements necessary to the nourishment of the plumage. You would find a constant supply of cuttle-bone of great service in keeping the plumage in good condition—a piece placed between the wires of its cage would afford the birds much healthy occupation in nibbling at. Discontinue any sweet food you may have been in the habit of giving it, and diet the bird for a time with Rape-seed of the smaller kind—that of a purple or reddish hue is the best, being of a cooling nature. Give it also some Lettuce-seed; this, acting as a slight purgative, will assist in carrying off any ailment it may have contracted. In cases of this kind, a few drops of Parrish's chemical food in the drinking water are found to be useful, containing, as it does, the material necessary for the elaboration of new feathers.—S. S. G.

POULTRY.

Fowls laying soft-shelled eggs (*Miss Jessie M. Smith*).—You are probably feeding your fowls too liberally. Most poultry ailments are caused by overfeeding or the use of unsuitable food, and you are evidently giving too large a proportion of Maize. The free use of this leads to the formation of interest fat, and, as this accumulates, the hen falls a victim to disease. The only time when Maize may be freely used for poultry is during very cold weather; at other times it should be dealt out with a very sparing hand. Change of diet is one of the main points to be observed in the management of the poultry-yard, as thereby not only is an increased yield of eggs insured, but the stock, both old and young, will thrive

the better for it. As to the quantity of food required by each bird to keep it in good laying condition, this is a question difficult to decide, but a good rule to follow is not to throw down all the food at once at feeding time, but to scatter it slowly and thinly, and to stop the supply directly the fowls begin to hesitate and to select and pick about before swallowing the grain. Well crush the oyster-shells you supply to your birds. You cannot depend upon obtaining fertile eggs much before April, the male bird having been hatched so late last season.—S. S. G.

LAW AND CUSTOM.

What notice is necessary to determine the tenancy?—On September 29th, 1900, I took a cottage on quarterly. There was no written agreement. I have paid all my rent quarterly, and have receipts for same. Can my landlord compel me to leave before Sept. 29th? Am I not a yearly tenant, compelled to give or receive a quarter's notice on June 24th, so that the tenancy shall expire on Sept. 29th, and how much notice must the landlord give me if he wishes to raise my rent?—ONE IN DOUBT.

[You say you took the cottage on quarterly without a written agreement, and this implies that you are a quarterly tenant, but, as you claim to be a yearly tenant, it would seem there is some misapprehension. If you took the cottage at so much a quarter from September 29th, you are a quarterly tenant, and your tenancy may be determined on any quarter day by notice given for that purpose on or before the previous quarter day. If, however, you took the place at so much a year, you are a yearly tenant, even though the rent be actually paid quarterly, and you are entitled to half a year's notice to quit, expiring with a year of tenancy—that is, on September 29th—if you have made no express contract for some other period of notice. Your landlord cannot raise your rent without your permission while your tenancy continues, and so the same notice is necessary if he wishes to raise the rent as if he desired to determine the tenancy and compel you to quit.—K. C. T.]

Notice to quit—right to remove fruit-trees (*Alpha*).—You say you took the house and garden on a yearly tenancy from June, and so the notice served on you in October to quit in April is bad, and you cannot be compelled to quit at that time. In the absence of an express contract to the contrary, a yearly tenancy can only be determined at the same time of the year as it commenced. You should inform your landlord that the notice is bad, and that you will not quit. The payment of the rent quarterly does not make the tenancy quarterly, and the fact that the place was taken at so much a year constitutes the tenancy yearly in the absence of any definite stipulation or contract for some other term. As your landlord gave you permission to plant the fruit-trees and to take them up when you left if your successor would not pay for them, you may take them up when you come to leave; but if your landlord denies his promise and sues you, and the court does not believe your version to be proved, damages may be given against you. You cannot claim compensation for the fruit-trees and fruit-hedges from anyone, but should you leave at Midsummer you would be able to recover compensation for the fruit then growing on the trees and hedges, and also for all other growing crops. You could in no event claim compensation for the flowers you have planted, neither could you remove them. Unless the notice to quit served in October contained the words "or at the expiration of the year of your tenancy, which shall expire next after the end of one half-year from the service of this notice," or some words to the like effect, the notice you have received is altogether bad, and a fresh notice to quit at Midsummer, 1903, will be necessary to determine your tenancy. It is presumed that your tenancy runs from Midsummer, and that you did not enter by arrangement during the currency of a year of tenancy. If this was so, and the tenancy was from April 6th, the position is entirely altered, although even then the notice is bad as being some days too short, unless there is a local custom for such notices to be given on October 11th.—K. C. T.

Squirrels (*J. R. Seymour Trower*).—We have never known these little animals to breed

in captivity, and should think it very improbable that they would ever do so, kept, as they usually are, in a little cramped box or wheel-cage. If provided with a spacious cage, or suffered to go at large in a room furnished with branches or hollow stems of trees, they might possibly be induced to breed. In a natural state, squirrels build high up in trees a nest well fitted together and waterproof, being formed of leaves and Moss on a platform of sticks, and roofed over. The young ones are usually born in June. We are unable to say to what age squirrels will live in a state of confinement; after a few years, however, their claws become long and their teeth turn yellow—signs of old age.—S. S. G.

GARDEN WORK.

Conservatory.—Among fragrant flowers which may be had in blossom during the spring, and which are always appreciated, are Heliotropes, Lilacs, Mignonette, and Musk. Of course, Musk is a very common plant—too common, perhaps, for modern ideas. Nevertheless, I think most people will appreciate a pot or two of Musk. The old-fashioned Musk is the most fragrant, but Harrison's is the largest, both in blossom and foliage. Musk may be grown in baskets. I have seen very effective baskets filled with Musk, and the young shoots pegged round the sides of the baskets completely covering the Moss. This is the time when Musk is usually started; it soon responds to warmth and moisture. It may also be raised from seeds—at least, the common sort may. I have never raised Harrison's variety from seed. Heliotropes struck in autumn and pinched back will now be breaking freely, and will soon be ready to shift into 5-inch pots. Cut-back plants, now in 5-inch pots, will be ready for a shift into 6-inch pots, and will soon develop into good specimens with a little pinching. As regards potting, a good compost for soft-wooded plants may be made as follows: Two thirds best turfy loam, one third equal parts old manure and leaf-mould, with one-eighth part of what may be termed porous materials, such as sand, wood-ashes, or crushed charcoal. The latter broken fine are very useful mixed with the compost, as most plants seem to thrive in it when used in moderation. The above compost may be used for pretty well all greenhouse plants except hard-wooded plants, such as Hebes, Azaleas, Camellias, and new Holland plants generally. Many of the latter will do very well in yellow loam; but loam from a limestone soil will not do. The loam in a limestone or chalk district may do very well for fruits, but is not adapted for flower-growing. Hydrangeas will now be throwing up their flowers in a warm-house, from whence they may be taken to the conservatory when about to expand. Hydrangeas, if wanted early, will stand a good deal of heat. Of course, the growth must be well ripened and rested before forcing begins.

Stove.—It is not difficult to have a few Orchids in flower now in a cool stove where the night temperature ranges from 60 degs. to 65 degs. Cyrtopodiums of the insigne section will do in a lower temperature. Several of the Dendrobiums, including *D. nobile*, are in flower now. *Phaius grandiflorus* is very easy to manage, and makes fine specimens in a comparatively short time. The *Calanthes* also are easily managed. The most important matter in Orchid culture is free drainage. The specialist has special pots abundantly supplied with holes for the escape of the surplus moisture. Then the potting or the basketing material is of the most fibrous character—peat, with all fine matter taken out, Sphagnum Moss, chopped fine, charcoal, broken into various sizes to suit the different-sized pots. Fill the pots half full of broken crocks, charcoal, etc., so as to ensure a dry, porous bed, and on this place the plant and fill in with the prepared materials, and press in as firm as possible. This treatment will grow most of the easily-grown species. Many Orchids are grown in baskets, and others on blocks of wood surrounded with Sphagnum, but we will not refer to these now. The beginner will do better with the terrestrial species, though many of these may be grown in baskets suspended.

Training down Vines.—In many small houses the Vines are trained too near the glass,

and the foliage suffers in consequence. The best distance is from 16 inches to 18 inches; this gives room for the foliage to expand without coming into contact with the glass. In planting down some care is required, as, if a branch splinters off, a blank is left, which is always a reproach to the gardener. It is best and safest to draw the shoots down to the wires gradually. Put a string of matting or Rofia round the shoot and form a link, and bring it down as far as it is safe. In a day or two more pressure may be given, and in the course of a week the shoot will be in position and no harm done. If the Vines are closely planted one generally has to be content with one leaf beyond the bunch, though where there is room I like to have two. A Vine cannot have too much foliage if there is room for full development; but in no case should overcrowding be permitted. The night temperature at this stage should range from 60 degs. to 65 degs. Muscats a few degrees higher. The fertilisation of the blossoms may be greatly assisted by shaking or tapping the pedicels to dislodge the pollen about 11 o'clock in the forenoon or when the pollen is dry. The internal moisture must be regulated by the outside conditions. During bright, sunny weather damping down once or twice a day will be required. Some houses require more attention than others, and the smaller the house usually the more internal moisture required, and more care should be taken with the ventilation. But rather than give much air on cold, bright days, I should increase the internal moisture.

Ferns under glass.—This is the most natural season for repotting, although, of course, repotting where many Ferns are grown is always going on. Some plants may only require to be shifted into larger pots without reducing the ball; others may require more or less of the old soil taken away, and be started again in smaller pots. The best general compost is one-half to two-thirds good loam and the remainder leaf-mould and peat, with a good proportion of sand. Some species do well in pure loam, rather heavy in character, notably *Adiantum Farleyense*. In all cases the potting should be firm. When potted loosely the growth is often lacking in robustness. If possible, after repotting increase the temperature a little. Use moisture in the atmosphere freely, but not much at the roots till they begin to move a little. If any plant is infested with scale throw it out; this is the best remedy.

Window gardening.—At the time of writing the weather is very severe, and the probability is that unless some care is taken the window plants may have suffered. There is no better protection than covering with paper in the warmest place in the room. Plants in the spare room may be moved to the centre of the room and placed on some old carpet on the floor, and then covered with several thicknesses of paper, and left there till the weather changes, and, of course, no water will be required by such things as Geraniums during frosty weather.

Outdoor garden.—In open weather all kinds of planting may be done. Those who buy large trees and shrubs must not only plant carefully but watch them narrowly during spring and early summer. Staking, mulching, and, when necessary, watering must have attention. Damping over the foliage of evergreens in dry weather in the afternoons has great value till the roots become active, and when this is done there is very little risk of loss. This is even better than too much saturation of the soil round the roots. Rockeries may be renovated and top-dressed with good soil. It is advisable at times to pull down and remake where the strong things are overrunning the weakly ones. The choice things should have special sites prepared and the strong growers moved to the background. It is better and more effective to group each family by itself, and then the right treatment can be given. The herbaceous borders may be planted on the same lines to a considerable extent, though, of course, where there are several borders variations may occur with advantage. What I should like to see is more originality, and this can only be obtained by leaving the matter pretty much in the hands of the owners of the garden. There will be a good deal of propagating to do now where bedding exotics are much used. Soft cuttings and sashed will make good and speedy work. Canes should

be divided and plunged in heat, or, at any rate, brought on in a warm house.

Fruit garden.—It is a good plan to plant a few rows of the best kinds of Strawberries now or soon, a yard apart, for the purpose of producing runners. The blossoms will be taken off as they appear, and the runners will be numerous and strong. In dry seasons fruiting plants do not furnish many runners, and they are often late, and for forcing it is important that the runners are taken early. I believe it is more economical to grow a few rows of plants specially for runners. Next year the plants which produce this season's runners will bear a very heavy crop of fruit, and a new bed planted this spring will supply the runners, only, of course, the runners should be planted now, so as to get a good grip of the soil before the hot weather comes. The bud-eating birds must be watched now and circumvented in some way or other. The best course is to prevent them getting a taste of the buds by dusting them with soot and lime, or adopting some other course. I have generally found soot and lime efficient, and it helps the trees in other ways. Those who are planting fruit-trees with a view to selling part of the produce must be very careful in selecting the kinds, and not plant too many sorts. Bismarck Apple has turned out a great favourite in some districts. Victoria Plum, though excellent, is not so much in favour as it was; it comes in a glut, and the sale is spoiled. Monarch is likely to do better.

Vegetable garden.—Sow Onions and Parsnips as soon as the land is in condition. Make the land firm for Onions, and grow the best kinds only. The same remark applies to all vegetables. Thin Early Horse Carrots in frames. As soon as the Asparagus which is forced in frames ceases to be productive, clear it out, put in some loamy soil, and plant with Potatoes or Lettuces. A well-fed Lettuce grown under glass is always of superior quality. When Onions are raised in boxes for transplanting, do not let the plants draw by keeping them in heat too long. The same remark applies to Cauliflowers and Early Peas. The Peas raised in pots should be planted on a mild, still day, after being well hardened in cold-frames. Draw a little earth up near the plants and stake them as soon as planted. If any further shelter is required, stake a few evergreen branches on the windy side. Clear the manure away from the Globe Artichoke and fork up the soil between the plants. The plants require a good deal of nourishment. The plants started under glass should be shifted into larger pots and be well hardened before planting out. Peas should be sown about every ten days, according to demand. There are plenty of good varieties; one can scarcely go wrong in making a selection. Potato planting should be pushed on now, especially early and second early varieties. Late sorts are not generally grown in gardens now. E. HOBDAY.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

March 3rd.—Finished sowing main crops of Onions and Parsnips. Sowed a few seeds of Turnip-rooted Beet on warm site for early use. Covered a lot of Rhubarb outside with pots to come after the forced lot. Earthen up late Seakale to blanch. We generally have a heap of burnt earth and leaf-mould for this purpose. Sowed Tomatoes for planting outside. Potatoes are being planted when the weather is suitable. Sowed Autocrat and Duke of Albany Peas.

March 4th.—Put in a lot of cuttings of *Dentzia Lemoini*. The young shoots strike freely in bottom heat. The flowers are larger and more robust than graceful, and the plant forces easily. The work in fruit forcing houses now is incessant. Diebudding, tying down, and stopping in the vines must not be neglected even for a day. Inside borders are closely examined at the beginning of the forcing season and watered from time to time as required. The chill is taken off the water, and usually some stimulant is given in the water.

March 5th.—Pruned Roses on south wall and tied in the shoots. We generally get early blossoms from this wall. The pruning consists in cutting in the old shoots, occasionally taking out an old branch to make room for the vigorous young

shoots, which bear the finest flowers. *Clonetta Jackmani*, against a 5 foot high wall, are pruned back near the ground every season and the strong shoots trained in—they generally reach the top of the wall by the time they begin to flower. *Jackmani superba* is an improvement on the type.

March 6th.—Planted Jerusalem Artichoke. We are growing the improved smooth variety. A small plot of ground has been planted with the Chinese Artichoke (*Stachys lanifera*). This is not likely to become popular—the crop is too light to be profitable. It is easily grown, and may please the seeker after novelties. Sowed a few seeds of Red Cabbage in a box. We generally sow these outside in autumn, but somehow they were overlooked; but only a few are wanted. Potted a further lot of Tuberoses. The first batch are throwing up flower spikes in heat.

March 7th.—Put in more cuttings of *Fuchsia*, *Ivy Geraniums*, etc. The propagating-house is fully occupied now with young stuff forming roots. When rooted, the cuttings are moved on to another house to harden a little, and are then potted off. Sowed seeds of *Grevillea robusta* and *Acacia lophantha*, both useful, easily-raised subjects, either for growing in pots or planted out in the sub-tropical garden. Put in cuttings of the Golden Elder and *Tamarix germanica*. These are useful hardy summer plants for massing when out hard back.

March 8th.—Sowed more *Mignonette* for succession in small pots in heat. Commenced grafting Apple and Pear stocks. Covered Apricots, where the flowers were beginning to expand on south wall, with fishing nets. The nets are firmly secured to poles to keep them steady. Vaporised *Pelargonium-house*. Early plants are forward in bud. Sowed a few seeds of Chinese Primulas for early blooming, and also *Primula obconica*. Moved a lot of *Azaleas* and other plants coming into bloom to conservatory. Good bushes of *Genista fragrans* are showing now.

CORRESPONDENCE.

Questions.—Queries and answers are inserted in *GARDENING* free of charge if correspondents follow these rules: All communications should be clearly and concisely written on one side of the paper only, and addressed to the Editor of *GARDENING*, 17, Southampton-street, Covent Garden, London. Letters on business should be sent to the Publishers. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper, and not more than three queries should be sent at a time. Correspondents should bear in mind that, as *GARDENING* has to be sent to press some time in advance of date, queries cannot always be replied to in the issue immediately following the receipt of their communication. We do not reply to queries by post.

Naming fruit.—Readers who desire our help in naming fruit should bear in mind that several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. The difference between varieties of fruits are, in many cases, so trifling that it is necessary that three specimens of each kind should be sent. We can undertake to name only four varieties at a time, and need only when the above directions are observed.

PLANTS AND FLOWERS.

Plumbeago (Ranunculus).—Plant is infested with thrips and red-spider, and you should apply the remedies mentioned advised for these pests.

Snails (Lilian Brodie).—The eggs you sent are those of one of the snails, probably the common garden snail (*Helix aspersa*). Certainly destroy all you can find.—G. S. S.

Failure of Joss-flower (Geo. O. Blacker).—The method is a very artificial one of growing the plant to which this name is given—for it is only the old Italian *Polyanthus Narcissus*—and if the bulbs are not strong failure is not surprising. Judging from the appearance of this sample sent, we think they want more light than they have been getting.

Ceraeus (W. F. Mears).—The shoots of your *Ceraeus Sieboldi* are not attacked by any fungus. The little openings in the bark are known as "lentils." They are respiratory organs, and the brown powder within them are portions of the cork in which the canals are loose so as to admit air between them. They may be touched upon any young twig, and are in no way a sign of disease.—G. S. S.

Early Chrysanthamums (Five Years Reader).—If your early flowering *Chrysanthomums* are to be planted outdoors to flower, they may be left to make quite natural growth. If to be grown in pots, they may be pinched once early in May, and then allowed to grow naturally. If you would like some to bloom later, then pinch again about the middle of June. It may be well to pinch some twigs to have a longer blooming season.

Cutting back Passion-flower (Hibernia).—If the young, healthy portions of your Passion-flower are cut

FRUIT.

PREPARATIONS FOR GRAFTING.

WHERE the regrafting of Apple and Pear-trees is contemplated it is high time the preparatory measure of heading back the trees was carried out and before the sap becomes too active. The practice of regrafting is an excellent way of renovating collections of fruit-trees in gardens and orchards, always provided the trees to be operated on are not too old and that they are perfectly healthy. It is a sheer waste of time and labour to regraft very old trees; the heading back serves to paralyse them, and if the scions take and growth is made they never form good heads, and as a natural sequence fail to bear good fruit. Much has been done within the last ten years in the way of orchard renovation, but it must be admitted much more remains to be done before orchards will be restored to anything like their former state of excellence. Thousands of young trees of good market varieties have been planted, and yet there are numbers of old trees still standing that are only fit to be grubbed. Among the healthy ones will be found many that bear indifferent or worthless fruit, and instead of allowing these to bear year after year crops of uneatable fruit, it is far better to head them back and graft them with a well proved variety or one suited to the district. Many of the inferior kinds of cider Apple-trees may with advantage be treated in the way described, or they may be regrafted with some of the better varieties which are known to produce good cider when the fruit is ground up and properly treated. Cider making has come very much to the fore the last year or two, and there is a prospect of a revival of this industry. Turning to garden trees, the same remarks apply with regard to the regrafting of inferior kinds of Apples and Pears, and an opportunity will thus be provided for anyone wishing to put the double grafting of Pear-trees to the test. Second and third-rate varieties of Pears, such as Bourré Clairgean, B. Boce, E. Bachelier, and others, will be excellent mediums on which to operate, as they are strong growers and impart a more vigorous constitution to some of the finer flavoured but slower-growing Pears. Should any of the trees to be operated on be cordons, cut them down to within a few inches of the stock, leaving just sufficient wood above the latter that the scion may be conveniently grafted on and be just clear of the stock.

Pyramids and bushes of both Apples and Pears should have the branches reduced to six or eight. Have these about 6 inches long; they will then quickly make good heads again. Fan and horizontal trained trees may have their branches cut back to within a few inches of the stems, leaving sufficient wood to enable the grafting to be properly performed. Standards may have their heads reduced to the like number of branches recommended for bushes and pyramids, according to size and age. When these details have received attention, a sufficient number of scions must be prepared, and to keep them as dormant as possible keep them

in under a north wall or hedge, or where the sun cannot reach them. When large numbers of scions are required, it is not always possible to obtain a sufficiency of young wood for the purpose, but this does not matter, as the older wood may be used provided there are dormant buds upon it. Many of the old-fashioned grafters in the west of England will only use wood of this character.

With regard to the method of grafting, that called whip grafting generally obtains in gardens. Crown and saddle grafting may also be found necessary in some cases, and for orchard trees whip and cleft grafting are unquestionably the best methods. Success in grafting does not depend so much on the method adopted as on the manner in which it is performed, and the work is always best entrusted to an experienced person, especially when a number of trees is to be grafted. There must be a perfect union of scion and stock, and to this end the scions should be so cut that they fit to a nicety, if not on both sides certainly on the one side, and if this is not done failure will result. The tying or binding on of the scions is also another important matter, as they must be bound on firmly, but not to such an extent that the ligatures will cut into the bark. Broad strands of Cuba bast or raffia are the best materials to employ for this purpose. The final operation is of course the smearing over of the point of union with grafting wax or clay. The former is now generally used, and it saves no end of trouble. Claying, however well it may be done, will, and does, crack, and requires a deal of attention if air is to be excluded. Grafting wax is much more portable than clay, it is more easily applied, and can be bought ready for use, and finally it has the great recommendation of being cheap.

NOTES ON STRAWBERRIES.

WHERE small or indifferently rooted Strawberry plants were pricked out into a nursery bed last autumn with a view to transplanting them in spring, the ground intended for them should be prepared as soon as possible, as Strawberries always do best in a firm root-run; moreover, the ground when dug becomes pulverised and sweetened. Bastard trenching is best, and a liberal quantity of well-rotted cow or pig-manure should be incorporated. March is a good time for planting, which must be done carefully with a trowel, securing as much soil to the roots as possible. Plant firmly, and mulch round each plant with a little leafy refuse or old horse-droppings to keep the roots moist. Established plants in light soil if not already mulched should now be done. Many fail with Strawberries in light soils through neglecting this important operation. I grew varieties of the Queen type, including Ganton Park, successfully for some years in a lightish, not very deep, soil, and I attributed my success to well mulching the plants with pig-manure in November or early in December. The manure, which was of a somewhat strawy nature, was well saturated with the urine, which was washed down to the roots by rain during winter, the strawy nature preventing undue evaporation, and also keeping the fruit clean. In the case of

plants in heavy soil, early mulching is not so important, but it should not be postponed later than March. An additional light mulch of clean stable-litter or Bracken should be given just before the plants flower to keep the fruit clean. I think the new Strawberry Lady Sutherland has a future before it, as it has a hardy constitution, and crops freely even in light soil—added to this, the flavour is delicious and the colour very striking. In many establishments Strawberries that are being forced are now in flower, and will require careful treatment for a week or two. Many a fine lot of bloom is destroyed by insufficient air and too much atmospheric moisture. A temperature of 55 degs. and a fairly dry atmosphere suit the plants best when in flower, the heat being increased to 65 degs. by the time the Strawberries are as large as Hazel Nuts. The plants should be placed on a shelf, close to the ventilators, and when in flower should have plenty of room, to allow of a free circulation of air amongst them. The bloom trusses should be reduced to two or three on each plant as soon as they are formed, this increasing the size and improving the quality of the fruit. Liquid-manure, the colour of pale ale, may be given at every watering, except when the plants are in flower. The flavour of forced Strawberries is often complained of, but it may be much improved by placing the plants in a cooler, drier house for a few days before gathering it. Royal Sovereign and Vicomtesse Hericart de Thury are, in my opinion, the two best varieties for forcing. J. N.

COVERING VINE BORDERS.

OPINIONS differ as to the wisdom or otherwise of covering outside Vine-borders with laves or other protecting material in autumn, some even asserting that borders containing the roots of Vines that are to be forced early do not require it. My experience, however, is that late as well as early vinery borders are immensely benefited by a good covering of some dry, warm material in winter. In a garden where I was employed the early vinery was always started in November, the Grapes—Hamburgh and Buckland's Sweetwater—being in variably ripe in May. The border, which, like many of the old ones, was elevated considerably above the ground level, was annually covered with dry leaves to a depth of about 18 inches, and afterwards well thatched with Reeds. The thatch being very slanting, a good deal of the rain which fell during the winter ran off instead of penetrating the border, thus keeping it in a dry, warm condition and preserving the fibrous roots which lay near the surface. The covering was removed piecemeal in spring, when the Grapes were approaching maturity, the last layer of leaves being taken off in May, and the border was then examined. The surface was found to be literally a mass of fibrous roots, which I am quite certain it would not have been had it been left uncovered all winter. The fact is, the covering, though not communicating any heat to the border, prevented that already in it from escaping, and so preserved the surface-roots intact. The Vines were forced early for twenty-six years in succession, and never once missed a

crop. In the same garden were two other varieties that were not forced, but allowed to come on gradually with sun-heat. The borders were not covered in winter, and it was a difficult matter to find a living root within a foot of the surface. Of course, a covering of wet, sloppy manure which one sometimes sees applied is worse than none at all, but I am confident that if only 9 inches or a foot of even long stable litter or Bracken is laid on the surface it will prevent many of the most valuable roots which always lie near the surface from decaying. I ought to mention that snow was always cleared off the thatch on the early Vine border with a large home-made wooden hoe with a long handle.

J. L. N.

HIGHLY-FLAVOURED GOOSEBERRIES.

THOUGH many new Gooseberries have been introduced during the last half century, a few of the very old varieties still remain popular. Warrington is probably the best flavoured red Gooseberry known, added to which it is a capital grower and bearer, and will hang on the trees longer than any other sort. The finest bushes I ever saw grew behind a north wall, the wall being covered with Morello Cherries. I have known the fruit hang till the middle of September, when it was much appreciated, as most other small fruit was getting past. Both the Cherries and Gooseberries were protected from birds by fish-netting, which was fixed to the top of the wall, and rested on a rough wooden framework. Whitesmith, a handsome smooth-skinned white variety, is unequalled for flavour by any other variety of its colour. It, too, is a vigorous grower and prodigious cropper, and, unfortunately, a special favourite with blackbirds and thrushes. As soon as the fruit approaches ripeness they attack it. Ironmonger, another very old variety, still holds its own as the best of the small fruiting section. It is red and juicy, much resembling Warrington, but is much smaller. It is the heaviest cropping variety I know, and grows so freely that quite small trees make large bushes in a couple of years. It is unrivalled for jam-making, and is an excellent market sort.

NORFOLK.

CARE IN PLANTING FRUIT-TREES.

The planting of fruit-trees goes on from the end of October until April in dry, light soils. As a general rule, they should be planted as soon as possible. In moist, clay soils it is often better to wait till the spring. Where it is necessary to plant late—i.e., in March or April—it is well to procure the trees as went in the autumn and lay them in in light, well-drained soil, after having trimmed off the damaged parts of the roots. In that case we should recommend the following treatment for the roots: Put four or five spadefuls of mould and two or three of thin cow-manure in a tub, adding enough water to make a thin puddle, in which the roots of the trees are to be plunged and turned over and over until quite coated with the mixture. Plant when the roots have dried a little. This way is very favourable to the development of the fibrous roots, and we have always found it give excellent results. In the case of large trees we recommend this as a preparation for autumn planting. The ground having been thoroughly broken up, holes should be dug just large enough to receive all the roots comfortably. It is very important when we have to deal with clayey and moist soils to take account of the depth of the freshly dug soil. Care should be taken that the collar is close upon 4 inches above the edge of the trench or hole, so that the graft shall not be covered when the soil is filled in. If the planting is done in dry weather it is well to water each plant so that the soil may be washed well in among the roots. It is indispensable in the case of Peers grafted on the Quince and Apples on the Paradise and Crab that the union of the stock and chosen variety should be left uncovered for 1½ inches, or the variety will strike out on its own root, which would be a serious drawback, so causing the trees to lose much of their fertility. When planting Apples or Peers grafted on natural stocks, as these are tap-rooted, the roots should be trained in a horizontal direction, on the principle that the nearer the roots are to the surface of the soil

the more fertile will be the trees and the more juicy the fruit.

At the foot of each tree when planted leave a slight hollow in the soil all round, and if the soil is dry it will be necessary to water. To complete the work it is advisable in spring to mulch round the foot of the tree, in order to keep the soil cool and promote the development of the young roots. If the soil continues dry it will be necessary to obtain the requisite moisture by copious waterings every fifteen days. In planting walls the trees should be inclined towards the wall, so that the grafts shall be 4 inches to 5 inches or so distant from it. When planting in this manner in freely dug soil it is very important not to fasten the trees permanently to the wall, as the settlement of the soil would cause it to remain suspended from the wall. The proper way is to fasten the tree loosely at first.

NOTES AND REPLIES.

Pruning Black Currants.—Amateurs often do not prune their Black Currants sufficiently, hence sun and air cannot reach the fruit, and it is consequently small and of poor quality. The fruit being borne on the previous year's wood, this, in order to obtain satisfactory crops, must be strong and well ripened—conditions only obtainable by freely thinning the trees out. The shoots should be clear of each other, and the centres of the trees be kept well open. Another common mistake is digging amongst the roots—by which many of the most fibrous and best roots are destroyed. The surface should be loosened with a fork and a good mulch of cow or pig-manure applied, and, if several good waterings can be given during summer, so much the better, as both the weight and quality of the fruit will thereby be much improved. Black Currants succeed best in a moist situation and deep, rather retentive soil, but will do well in any sunny position and decent soil, provided the roots do not get dry. Cottagers often make a good sum of their Black Currants, and might make a much greater if only they would cultivate them better, as the fruit is in great demand, not only for puddings, pies, and jam, but also for jelly and wine. In my opinion, Lee's Prolific is the best variety, the old Naples being also excellent. Black Champion is very large, but, according to my experience, it does not crop freely. Black Currants are often planted too closely together, and in a few years the trees become crowded. A space of at least 6 feet all ways should be allowed between them.

Pruning Red Currants.—Where pruning has not already been done, this should be taken in hand at once. The object of the pruner should be to have no more fruiting branches than can be exposed to the light, for where these are overcrowded the fruit does not ripen so well, neither does it hang so long afterwards. Bushels of fruit often rot on the trees when the weather has been showery during July and August on account of its not being sufficiently dry for gathering. The nearer a cut is made to a bud the less chances there are of dead sprouts to harbour insect pests. When the trees are pruned they should be dressed with newly-slaked lime and soot, or the latter alone will clear the bushes of soot. If put on when the trees are damp, it will stick freely, but if the weather is dry they should be syringed with water in which a little soft-soap has been dissolved, then dusted afterwards. This will need repeating later on should birds attack them just as the buds are pushing. Where the Currant sawfly is troublesome the above remedy usually keeps it in check. It is well to put in a few cuttings each season to provide plants to replace any which may be destroyed or for making new plantations. The making of these could be taken in hand during bad weather where it has not already received attention. The cuttings ought to be from 15 inches to 18 inches long, and all buds should be removed except three or four at the top. When inserted in the soil there should be a clear stem of from 6 inches to 9 inches above the ground. Trees against walls should be spurred in as close as possible. If the spurs are allowed to stand out some distance the coping does not protect the fruit from the rain, and therefore it does not keep so well or so long as when it is close to the brickwork.

Autumn treatment of fruit-trees under glass.—Many people overlook the

importance of, and the necessity for, closer attention to the requirements of various kinds of fruit-trees and Vines after the crops have been gathered. It is impossible to grow really fine fruit on trees that have been much neglected any time from the fall of the leaf to the time they are blooming again; in other words, more depends upon the size and perfect formation of the bloom-buds than we, as a rule, are aware of. According to my experience, the size and shape of the future fruit is more determined by the autumn treatment of the trees or Vines than by the treatment given when the fruit is swelling off. Large and perfect flowers or bunches of flowers may with ordinary good treatment be grown into large and perfect fruit or bunches of fruit as the case may be, but undersized or malformed blossoms cannot by any treatment be grown into full-sized, handsome fruit. If any proof of this is required, I need only direct attention to the state of Apple, Pear, and Plum blossoms when injured by frost. Where the strongest and best formed flowers escape destruction by frost, there are to be seen good crops of fine, well-shaped fruit, but where these were destroyed, the small, late, and in many cases imperfectly-formed blossoms were followed by correspondingly inferior fruit. A superficial observer might naturally form the opinion that a strong, healthy fruit-tree with only a small quantity of fruit set would swell these to a great size, but no such thing occurs, unless, indeed, such fruit resulted from the best-formed flowers. To a certain extent Dame Nature determines the quantity and quality of our outside fruit crops, but the case is very different under glass, as here we are in a position to be more independent of the climate.

Pruning Gooseberries.—Some of the buds of the early kinds are getting forward, and where the bushes have not already been pruned this should be taken in hand forthwith. In places where birds are very troublesome this is usually left alone as long as possible, for sometimes when pruned early the bushes are so denuded of buds that the crop is a complete failure. Many are the contrivances adopted to scare the birds, but the safest plan in country places where the gardens are surrounded with woods is to cover the quarter where Gooseberries are grown with small meshed wire netting. It is, however, not in every place that this can be provided; hence the necessity for having recourse to other means. Lime will, if applied in time and repeated if washed off, often deter sparrows and other small birds unless the weather be very severe. In pruning see that the centre of the bush is well opened out, that the light and air may get at the fruit and facilitate gathering. There is a considerable difference in the habit and growth of the large kinds and those that produce small fruit, also in the time of their pushing their buds. The former being much earlier suffer far more from the attacks of birds than the latter; the shoots, too, are inclined to grow downwards instead of in an upright direction, so that the fruit on the lower branches, unless these are kept well up from the ground, often gets spoiled by the heavy rains. For this reason when pruning, branches that have this tendency should be removed. Gooseberries do well as cordons, espaliers, or trained against walls; the fruit from such is far finer than it is from bushes, and it may be more readily protected from birds. Some of the best dessert kinds should be selected for planting and growing in this manner, as by so doing a supply of fruit may be had till quite late in the season. When grown against walls a north or north-west aspect should be chosen. When making cuttings of the large kinds endeavour to have them as long as possible. If they stand a foot out of the ground before putting on any branches so much the better, for then there is far less likelihood of the fruit being splashed by the rain.

"Farm and Home Year Book."—We are glad to be able to state that the "Farm and Home Year Book" seems to have met a want felt by our readers. Its reception by the Press generally has been most cordial, and the demand for it has been so great that a third edition has been issued. Our readers should have as difficulty in obtaining it from any local bookseller or newsagent, who will order it. If it is not in stock; or they may get it direct from the Publisher, 37, Southampton-street, Strand, by post, for 1s. 6d.

PLANTS AND FLOWERS.

RHODODENDRON LADY ALICE FITZ-
WILLIAM.

GREENHOUSE Rhododendrons are well worth the attention of all who have any greenhouse accommodation. The variety represented in the illustration succeeds admirably in any ordinary greenhouse temperature, and when in bloom emits a delicious and refreshing perfume. There seems to be a quite prevalent idea that in order to be successful with this class of plants they must be subjected to a sort of starvation treatment. This is an erroneous idea. Of course, any plant which has been starved for any length of time must not have rich soil placed within reach of its roots at once; it must be gradually toned up with manurial stimulants until the roots are in an active, healthy condition, when a richer compost may with advantage be given. Peat is not absolutely essential to the welfare of Indian Rhododendrons. I grow and flower them well in a compost of leaf-mould, turfy loam, well-rotted

drons are being hoit op into apецimens no liquid-manure is required. It is only when the plant or plants have reached the aforementioned pot-limits that liquid-menure is necessary to maintain them in a vigorous state for some years thereafter, until another shift may be necessary to prevent deterioration. The best kind of liquid-manure for pot-grown Rhododendrons I have always found to be that which drains from a manure heap into an arranged receptacle. It must always be diluted with water—tepid in winter—and may be given frequently to pot-bound plants, especially during the growing period, with most beneficial results. A most important cultural point is to keep them at all times abundantly supplied with root end atmospheric moisture, and not to subject them to a high temperature, unless during the period of annual growth, when a higher temperature, although not really necessary, is distinctly beneficial. As soon as growth is completed, the plants should be placed out-of-doors in a sheltered spot for a month or two, this helping to solidify the young wood, thus encouraging the free formation of bloom-buds. Those formed and developed to the bursting

wire frame, but it has not flowered for the last three or four years. Could you tell me what treatment to give it in order to induce it to bloom?—HUYA.

[There is evidently some mistake in the cultivation of the plant, as it usually flowers somewhat freely. It is quite necessary, however, to get the wood well ripened each year, and perhaps your plant is overcrowded. If possible, we think you had best report it, say early in March, and at the same time thin out some of the small shoots. In the potting employ good yellow loam three parts, and one part rough lumpy fibrous peat. To this add a liberal addition of old mortar rubbish and some sand. Give a perfectly free drainage of about 3 inches, and pot rather firmly. After potting place the plant in the warm greenhouse, but do not water for a day or two, preferring to use the syringe till the plant is taking to the fresh soil. During summer grow the plant in as sunny a place as possible. It is highly probable the plant has been too much in the shade.]

Begonia Gloire de Lorraine.—Will you tell me how to manage Gloire de Lorraine Begonia, always a failure here?—YEO VALR.

[If you have old plants of this, you had best cut them down as soon as flowering is over, keeping them rather drier at the root than usual. Some time later cuttings will issue from the base, and these when 2 inches or 3 inches long may be inserted as cuttings, placing one cutting in a pot of 2½ inches across. Plunged under a bell-glass, or in a frame where gentle bottom-heat is at hand, and kept cool moderately moist, the larger number will root in about a month, when more air may be given, and be presently potted into 4-inch pots. From this time daily watching will be necessary, and particularly in watering, never getting the plants too wet. Finally, as the plants fill up the smaller pots with roots they may receive the final shift to 5½-inch or 6-inch pots. The soil should be of loam, peat, leaf-soil, and sharp sand, about equal parts of each. Temperature 50 degs. to 55 degs. for growing, and rather more for the cuttings. Perfect drainage, with constant care in growing, are the chief items, as any neglect cannot be undone. A light position and ample room are necessary from the start.]

Imantophyllum miniatum.—I have several old, well-established plants of the above in 12 inch pots and tubs. I get few flowers. Can you give me suggestions as to culture?—SWALLOW.

[Imantophyllum miniatum will succeed with ordinary greenhouse treatment, or in a light position in the window of a dwelling-house. It should be kept somewhat drier during the winter than at other seasons. When growing freely it may be potted each spring as soon as the flowering season is over; but in the case of large plants once every two years will be sufficient. Good drainage is very essential. It can be propagated by division, and also by seeds. Division is best effected directly after flowering, when, if part of the soil is removed, the suckers, which are often pushed up from the side of the main stem, may be separated with a few roots attached to them, when they must be potted into small pots. To ensure perfect seeds the flowers must be fertilized. The berries, which take months to ripen, should be allowed to remain on the plant till they show signs of dropping. Then sow in penes of sandy soil and cover with about ½ inch of the same compost. In gentle heat the young plants will soon make their appearance. Two-thirds loam, one-third leaf-mould, and a good sprinkling of sand will suit the Imantophyllum.]

Aspidistra falling.—I have for twelve or fourteen years been most successful with variegated Aspidistras, but of late have several times noticed the nice fresh new leaves fall over the side of the pots, and cannot be made to stand erect without support. Is this because they are not planted deep enough?—AMATEUR.

[Judging by the young leaves dropping over in the manner described, it would appear that your Aspidistras have been deprived of sufficient light, while other matters might also have contributed to the state of ill health into which they appear to have fallen. What the cause are are only conjecture on our part—the drainage may have been in a bad state, the soil, perhaps, kept too wet or too dry, while the soil itself may be very unsuitable. Our advice is, during the winter to give sufficient water to keep the soil moderately moist, but take care that there is none allowed to stand in the pans or saucers in which they are potted. Then keep them in a moderately light position

Rhododendron Lady Alice Fitzwilliam. From a photograph sent by Mr. W. A. Leslie, Cormiston Gardens, Biggar, N.B.

animal manure, and sand, with some pieces of charcoal added. The major portion of the compost should be leaf-mould. These materials—excepting the charcoal, which is best added just prior to the potting—should be thoroughly incorporated, and then stacked for some considerable time previous to their use in order to induce mellowness, anything of a rook nature in the way of soil being most hurtful. Young plants ought to be grown on quickly into fair-sized specimens ere they are permitted to become much pot-bound. This is managed by giving a small shift every year until a 10-inch or 12-inch pot is reached. Firm potting is essential on each occasion, and a potting-stick must be used in order to ensure the soil being thoroughly rammed into every crevice around the ball. A little extra warmth after repotting tends to induce quick root-action. Considerable care must be exercised in applying water to the soil for some time after repotting. A superabundance at this time is quite as injurious as an inefficiency. The plants must also be carefully shaded from bright sunshine until established in the new pots.

During these years when young Rhododendrons

stage, care must be taken that the wood-hurds directly underneath are not permitted to coat the flower-buds. Wood growth must be assiduously kept in check until the flowering period is over. There is, however, little or no trouble with premature wood growth in well-ripened plants.

The foregoing remarks apply exclusively to the subject of the illustration and its companions. The jasminiflorum type requires a somewhat higher temperature throughout—such as that of a cool stove—to do them well; otherwise, the requisite cultural conditions are much the same.

WM. A. LESLIE.

NOTES AND REPLIES.

Smilax rotundifolia.—Is Smilax rotundifolia evergreen, and can you or any of your readers tell me what nurseryman would be likely to have a plant of it in stock, and is it as hardy as Smilax laurifolia?—ANXIOUS AMATEUR.

[This, also known as S. quadrangularis, is a high-climbing species with large, thin, and nearly round leaves. The stems are terete and the branches and young shoots often four-angled. The prickles are stout, scattered, and sometimes a little curved. It is a native of N. America.]

Hoya carnosa.—I have got a large specimen of this in a pot. It is trained over a bell-shaped

indoors, and sponge the leaves every week, both on the upper and lower surfaces, with water slightly warmed. This will remove the dust, which in a dwelling-house soon collects on the leaves and chokes up the pores thereof. Then, on the return of spring, your plants had better be repotted, clearing away the major portion of the old soil from the roots. There is a great tendency to overspot many plants, and in carrying out the operation it should be borne in mind that large plants can be kept in good health for years in comparatively small pots, provided their roots are kept in a healthy state. It is probable that the roots of yours are partially decayed, in which case, when repotting, take especial care that all signs of decay are removed. A very suitable potting soil for the *Aspidistra* is two-thirds loam to one-third peat or leaf-mould, and a liberal sprinkling of rough silver-sand. If the loam is of a particularly adhesive nature, equal parts of loam and peat or leaf-mould will be the more suitable.]

Heating a greenhouse (F. E. T.).—The stove, one nearly similar to that advertised by the "Twelve Hours Syndicate," in *GARDENING ILLUSTRATED*, is fixed in a small recess in kitchen outer wall, and the fine-pipe at back, instead of going straight up, has had a bend made from the stove, carried through the wall and up outside the house, being continued by piping as high as the roof to act as a chimney. This has been the only difficulty in connection with the arrangement, as with the wind in one particular direction it sometimes smokes when first lighted. Had space permitted outside the house I should have placed the greenhouse at the back of a small morning room, the chimney of which would have simplified matters, as the stove could have replaced the ordinary grate, and thus warmed the room, greenhouse, and radiator. However, the wells of kitchen being stone and floor cement, no fireplace was necessary, the recess made answering instead. The pipes from boiler are taken through the side of the stove instead of the back, and about a foot from the stove there is a double connection, one going through outside wall end supplying the 4-inch flow and return pipes for greenhouse, the other joined to the 2-inch pipes running along one side of the kitchen (through end wall of kitchen) to supply the radiator, which is at the end of wall nearest the kitchen, the well and kitchen being at right angles to each other. The radiator is one of the usual kind with twelve vertical pipes. The fuel I have used is coke, as I find coal burns too quickly and is apt to smoke; coke is also cheaper.—M. M., *Naira*.

Winter-flowering Zonal Pelargoniums (H. G. Thomson).—Quite a large number of the varieties usually cited under this head are adapted for winter work, and it is rather an item of culture than ought else, though, of course, even so some flower more freely than others when all are grown alike. At this time of year, with plenty of time in advance, the best way would be to purchase cuttings or rooted cuttings of what you require. The culture differs in this respect: That all attempts at flowering during the coming summer are closely discontinued, the spikes of flowers being picked off as soon as formed. This assists the plants to a freer growth, and by occasionally pinching out the point of the shoots induces a more bushy plant to form. Meanwhile, with the growth in progress, two shifts will be needed, the final and largest pot for the season being 6½ inches in diameter. In this size of pot good bushes with half-a-dozen strong growths each should result. Avoid a soil that is very rich, as this engenders a much too gross growth. Be sure the potting is very firmly done, so that the soil is quite firm—indeed, almost hard right through the ball. Nothing promotes the best class of flowering wood more than this, and, with the plants grown in an open, sunny spot with plenty of light, you should, in your favoured district, grow these things perfectly. The following are a good set and are free flowering: Ian McLaren, pink and salmon; Olivier, scarlet, white centre; Mark Twain, rose; Mrs. Williams, corise; Barbara Hope, pink and salmon, with broad margin, very large flower; J. W. Barrie, rose-scarlet; Conan Doyle, salmon self, extra good form; Dryden, scarlet, white suffused centre; Chancer, rose-salmon; Mary Beton, pure white; Mrs. E. Rawson, dark crimson, extra large flowers.

Mr. T. E. Green, pure scarlet, a remarkable colour; Lady Roscoe, pealeat pink, very delicate; Winston Churchill, purplish rose-magenta, with starry white centre; Lady Sarah Wilson, salmon-scarlet, netted with white; Niphotos, pure white. These are among the most approved kinds as at present grown, and cannot fail to satisfy if justice be done to them during the period of preparation.

Exacum affine and Vinca rosea (William).—Particulars of the general culture of the *Exacum* appear on page 679 of our issue of February 22nd. *E. affine* is an annual, and well grown forms a compact plant about 1½ feet high. It is a useful pot plant for warm conservatory, but requires a degree of moisture and warmth somewhat greater to grow the plants well. A moist intermediate temperature in a stove is a good place to grow the young plants, or, at any rate, a temperature of about 60 degs. You may grow the plant without pinching, or you may pinch the points out twice or thrice if you wish to delay its flowering and make it a larger size. The final shift will depend on your action in these matters. If, however, you require it for autumn and winter flowering, the plants may be stopped twice at least. Pot the seedlings into 3-inch pots as soon as ready, and when 3 inches high remove the point of growth. In April or early May the plants will be ready for a shift into 5-inch pots, and in the end of May the shoots may be stopped again. You had best gauge the stopping by the progress of the plants, and in any case the last stopping should be made no later than the middle of July, with the plants at that time in 6-inch pots. The object of all the pinching in the early stages of growth is to build up a bushy plant, and having done this grow the plant on for the production of bloom, after the style of *Bouvardia*. Pot very firmly and drain perfectly. Peat, loam, and leaf-soil, with a free addition of sand and a little bone-meal, will suit quite well. The most recent addition is E. Forbesi, which may be grown from cuttings, as it is perennial. You could also grow this a second year, and by giving it liberal treatment obtain fine bushes. It is a free-flowering and attractive kind. The *Vincas* may be treated to a similar soil, but of a more sandy nature and the addition of some well-decayed manure. The *Vincas* will require attention also in staking, and in other respects the same mode of treatment will suffice.

Dracena falling (Exiled Cockney).—Your plant of which you send leaf is not a "Palm" at all, but a species of *Dracena*. The cause of the leaves becoming disfigured may be over-dryness or the reverse—viz., too much moisture at the root. Either of these, with too low a temperature, or when the plants are grown in a room, will bring the plant into a bad condition, and the browning of the leaves follows as a consequence. You may improve matters—to the eye, at least—if you take a pair of quite sharp scissors and cut away the disfigured portions, leaving the point as near the natural shape as possible. If the soil is wet, allow it to become quite dry—almost dust-dry—as nothing tends to sweeten soil so much in winter time as this. Then, having got the soil quite dry and kept it so for a couple of days at least, stand it in a bucket of water that may be just chilled for ten minutes, allowing the water to cover the pot. If the plant is dry, and the pot responds with a good clear ring when rapped by the knuckles, so that it sounds hollow-like, you had best immerse it as above. You may still greatly benefit such a plant by giving a teaspoonful of any good artificial manure once a week for some time to come. Frequently this class of plant forms a "toe" at the base of the stem within the ball of earth, and this pressing perpendicularly against the bottom of the pot so raises the ball of earth and plant bodily from its place that a cavity is formed, and the water, instead of sustaining the plant, passes around the sides of the pot and escapes. In this way the plant suffers often without knowledge. The presence of the "toe" may be determined by the upheaval of the soil and roots above the margin of the pot.

As many of the most interesting notes and articles in "GARDENING" from the very beginning have come from its readers, we offer each week a copy of the latest edition of either "STOVE and GREENHOUSE PLANTS," or "THE ENGLISH FLOWER GARDEN," to the sender of the most useful or interesting letter or short article published in the current week's issue, which will be marked thus:—

CHRYSANTHEMUMS.

CHRYSANTHEMUMS—RAISING SEEDLINGS.

It is very seldom that the *Chrysanthemum* is raised from seed—in Scotland, at any rate. Raising the *Chrysanthemum* from seed is a very simple matter and most interesting, every new development in the growth of the plant being watched with interest. Most firms can procure the seed, although not offered in their catalogues, and even if dear the finest seed only should be procured, as by buying inferior seed you are only courting failure, and the same time and trouble are required in any case. The seed should be sown in February, or not later than the first week in March. Prepare a seed-pan by well draining it with crocks and filling the pan about a third full. Make up a compost consisting of equal parts fibrous loam and leaf-mould, with a good dash of sharp sand, all being passed through a ½-inch sieve. Place the rougher portions of the soil over the crocks and fill up the pan to within ½-inch of the top with the prepared compost. Scatter the seed thinly and evenly on the surface and cover slightly with fine soil or silver-sand, water immediately through a fine rose, and cover over the pan with a square of glass. Plunge the pan in a gentle hotbed, or place on a warm shelf, when seeds will soon germinate. As soon as the tiny seedlings are fit to handle, prick them off into boxes of good soil, 4 inches apart, and again return to the bed or shelf, as the case may be. After they begin to grow they should be placed on a shelf near the glass. The little plants will gain strength and vigor each day if well attended to, and very soon will touch each other in the boxes. Procure now a quantity of 3-inch pots, which should be clean and dry, and prepare soil similar to that in which the seedlings were raised, only a little bone-meal or guano may be added and the leaf-mould lessened. Pot each plant singly, leaving the soil ½-inch from the top, which will allow room for water, and return to the shelf after giving the plants a light syring. Under such treatment they should be nice sturdy plants by the second week in May, and can now be put close together in a cold-frame, standing the pots on a bed of coal ashes. As soon as the 3-inch pots are full of roots they may receive their final shift, using a pot not larger than 6 inches in diameter. In these they will show their respective merits, whether good or bad. The plants should be allowed to grow naturally from the beginning, it being advisable not to pinch seedlings, as by doing so you not only retard the flowering period, but you fail to see the flower in its true light. One good strong stake in the centre will be sufficient support. When the plants break (naturally) secure three of the strongest shoots, rubbing off all others by catching them between the thumb and forefinger. In September, or earlier, the buds will appear, generally in clusters on the end of each shoot; all the smaller buds should be rubbed off, retaining only the largest one on each shoot. It will be thus seen that each plant carries three blooms, which will be sufficient to show the grower the good points of each individual plant. Each plant should bear a number, written on a tally, from one upwards, so that if the grower should send blooms to be commented on by any of our societies he would simply label them with the number on the pot. Whether the grower be successful or not at first, he should not be disappointed. D. G. McL.

Bridge of Weir, N.B.

NOTES AND REPLIES.

Increasing Chrysanthemums.—I am anxious to get cuttings from nice plants of a very late *Chrysanthemum*—*Mutual Friend*. Two show no signs anywhere of cuttings. One has little shoots appearing on the stem, which flowered this winter. Are they any good, and will you advise me?—*TOURNAI*.

[Some varieties break up very late at times, and this is a case in point. The plants (if alive) will break away presently and give good sturdy cuttings. All you can do now is to place the old plants in a little more warmth to induce growth. The sooner growth from the soil makes the best cuttings, not those from the stem.]

Grafting Chrysanthemums.—Can any of your readers give any information respecting the grafting of *Chrysanthemums*—when and how it should be done?—J. H. D.

[This is usually performed in June, the "stock" having been grown on previously from an early-rooted cutting. Its best use is the

encouragement it affords to weak-growing varieties. The form that finds most favour is side grafting or inarching. This is done by bringing the plants together side by side, and by first cutting away a slice of bark 2 inches long, or nearly so, from the "stock" plant, and then, making a similar cut on the side of the shoot to be grafted, bring the two together, and carefully and closely unite and bind together the parts as prepared. Quicker and surer are the operations when inarching is done, as then no separation of the scion takes place until a union is formed. The plants should be in pots, and so arranged in a cold-frame that water can be applied to the roots. To make a tolerably certain union, the wood of stock and scion should not only be of about equal size, but as near as possible of the same firmness or maturity. Shade from hot sun for a few days, and keep the frame cool by gently sprinkling overhead with water.—E. J.]

when the plants, with their ball of soil attached, can be easily lifted and potted, boxed, or planted in the floor of the house. Plants treated in this manner throw magnificent heads of bloom whether grown in pots or in the open ground. They should be pinched three times, but not later than mid-July in the case of the plants in the open; those in pots may safely be stepped towards the end of that month, and, in either case, all buds formed should be retained.—D. McL.

ROSES.

YELLOW ROSES FOR THE OPEN AIR.

Will you kindly inform me the names of the deepest yellow Roses for outdoor culture?—C. F. S.

[Roses of a rich deep yellow colour that will flourish well outdoors are very few in number. Of course, by deep yellow we mean Maréchal

a climber, in the strict meaning of the term; it would, however, be suitable for a wall 3 feet to 4 feet in height. Its flowers are a deep yellow, the centre petals as rich as the yolk of an egg. Duchesse d'Auerstadt is a splendid rich citron-yellow Rose of exceptionally rampant habit, but rather shy blooming. This may to a certain extent be overcome with patience by spreading out the growths almost horizontally on the wall or fence. I have seen this Rose grown very successfully as a pillar, and it is certainly much hardier than many of the vigorous-growing Teas and Noisettes. A good plan to compel these pillar plants to blossom is to bend the growths serpentine fashion or twine them around three stakes stuck in the ground to form a tripod, taking care not to cut away the long, annual growths save those that are soft. Réve d'Or is a good deep golden-yellow Rose for growing in the same fashion as the last-named, or, if trained on a wire trellis in a sheltered

A border of yellow Roses, Harrisoni, &c., with hardy flowers beneath and background of flowering shrubs. From a photograph by Miss Willmott, Watley Place, Essex.

Niel colour when highly cultivated. Two of the best of recent novelties are Billiard and Barre and Prince Theodore Galitzine. The former is a strong grower, yielding large semi-double flowers of a rich golden-yellow. The latter is a dwarf-growing kind, possessing an excellent constitution, flowers deep orange-yellow. Both these I can thoroughly recommend for outdoor culture. One of the most distinct yellow Roses grown is Souvenir de Mme. Levet. Unfortunately, it is very tender in cold districts, but flourishes freely, I am told, in Ireland and southern counties. Its flowers are not quite so intense in colour as in Wm. Allen Richardson, but neither has it the defects of the latter in producing pale coloured blooms. Every flower of Souv. de Mme. Levet is perfect in colour. The habit of growth is very dwarf and the shoots stout, after the manner of a Hybrid Perpetual. Georges Schwartz is another fine novelty, deep canary-yellow in colour, and growth after the manner of Amazona. It is reputedly a cross between Kaiserin Auguste Victoria and Souvenir de Levet. It appears that this latter Rose will impart its beautiful colour to the offspring, so that by employing good, lusty growers as the seed parents it is hoped raisers will ere long produce some good results. Amazona and Jean Pernet are two very good yellow Roses, but one cannot quite term them deep yellow. Mme. Eugene Verdier is a fine Rose where it can be the protection of a west well. It is not

part of the garden, quantities of blossoms may be gathered from plants after they have become well established. William Allen Richardson comes more under the heading of orange-yellows, but it cannot be omitted from a list of deep yellow Roses. Perhaps, in standard form its beautiful buds are richest in colour. I would also recommend its culture as a bush, pruning it very moderately. (On a south wall the first crop of flowers is often of a very pale, nearly white colour, but there are many exceptions to this. I found a plant last summer growing on a full south wall, every bud and blossom being so rich in colour as one could desire. However, I should select for preference a corner where the plant did not receive the sun until after mid-day. One of the finest specimens I have ever seen was in such a corner. The plant, budded on the seedling Brier, was transplanted four or five years ago to its present position, where the soil is a deep, strong, clayey loam, thorough drainage being provided by the somewhat abrupt slope to the west.

Other good apricot and orange-yellow Roses that succeed well outdoors are Mme. Pierre Cochet, Mme. Faloot, Sunset, Mme. Charles, Françoise Kruger, Mme. Ravary, and Bonquet d'Or.

As early blooming kinds, Persian Yellow and the single yellow Brier (*Rosa lutea*) should find a place in every garden, the latter kind a real gem, and developing into fine bushes if grown in a natural manner, merely just tipping the growths annually and cutting out old and worn-out wood. Mme. Pernet Ducher, a raiser who has given us such good things as Mme. Abel

Chrysanthemum Mons. Willfam Holmes.—In the rush for new varieties nowadays one is apt to forget our old favourites. I think there are few so well adapted and so easily grown as this variety, especially for late October and early November work. The constitution of the plant is everything to be desired, and its height is not a hindrance in any way, seldom reaching over 4½ feet. The colour is best described as a rich dark terra-cotta, which changes to a lighter colour as the blooms age. It lifts well when planted in the open, a good ball of soil adhering to the roots, especially if the ground has previously received a slight shower. A good plan to follow in lifting these plants is one which I have often seen done, and which is to make a cut with a spade all round the plant, the cut being about 8 inches from the stems all round. This operation should be performed a week or ten days previous to lifting.

Chatenay, Caroline Testout, Marquise Litta, has lately produced what he describes as a new race of Roses, naming the race R. Peruetiana and the first variety Soleil d'Or. This race is of much promise, the colour being deep golden-yellow, shaded with Naestertum-red and rose colour. It is claimed for this Rose that it flowers a second time. Pot-grown specimens certainly blossomed twice. The flowers are rather irregular in shape, but it is undoubtedly a variety worth growing, and now that this raiser has produced such a Rose by crossing Persian Yellow with the Hybrid Perpetual Antoine Duchoer there seems a possibility of many useful novelties from the old, well-known Persian Yellow, and also from the single R. Indes. If we could obtain a perpetual-flowering single yellow as beautiful as R. Indes our gardens would be all the richer.—ROSA.]

NOTES AND REPLIES.

The Coronation flower.—I hope you may see your way clear to publish in your next issue the following letter from our President, which appeared in the *Times* of the 15th inst.—**RODWIN MAWLEY, Hon. Sec. National Rose Society.**

"Sir,—I venture to express the hope that the Rose, which is the National Emblem of England and the Queen of Flowers, may be worn in preference, not only at the time of His Majesty's Coronation, but on the anniversaries hereafter. At the date of the ceremony the Rose will be its most abundant beauty in all the gardens of the land.—I am, Sir, your obedient servant, S. REYNOLDS HOLE, President of the National Rose Society, *The Deanery, Rochester, Feb. 13th.*"

Roses for trellis.—I have a Gloire de Dijon growing against a trellis (no wall) and would like to plant three other yellow climbing Roses, out of pots, against the same open trellis. Would you kindly say which are the three hardest amongst the following: *Allister Stella Gray, Celine Forestier, Mme. Moreau, Réve d'Or, Thella, and W. A. Richardson.*—**ROMANIAN.**

[Of the list you submit, *Allister Stella Gray, Celine Forestier, and W. A. Richardson* would be the hardest for your purposes. *Réve d'Or* would be a splendid grower, freer by far than *Allister Stella Gray*, and much superior in blossom, only that it is not quite hardy, and it needs managing to obtain blossom. It is, however, well worth a trial as a trellis Rose. In some parts of the country growers find this good old kind succeed remarkably well trained out horizontally, cutting away all useless and sappy wood. A few Fir-boughs stuck among the branches would protect the wood. We recommend it with every confidence, if you can overcome the somewhat tender nature of the plant by artificial protection. *Thella* is a white Rose. Perhaps you are thinking of *Aglaia*. This is yellow in the bud, opening to pale primrose. It is a variety of much hardiness and vigour, but requires abundant space and absolutely no pruning in order to bloom it successfully.]

Pruning Rambler Roses.—I would be much obliged if you would kindly tell me how to prune the following Roses—*Crimson Rambler, Miss Wilmott, Lucy Hartman, Dundee Rambler, and Carmine Pillar*—that were planted last October in open spaces to grow as they please? How much should they be cut back, and when?—**L. F.**

[The Rambler and Brier Roses which you have planted with a view to treating them as large free-growing shrubs would be all the better for pruning back this season to about half the length of each growth, seeing that they were only planted in the autumn. Next year and afterwards the treatment will be quite different. Then they must be very sparsely pruned in spring—indeed, they will require no pruning then beyond removing dead wood and just shortening tips of shoots. The real pruning is done after flowering. This consists in cutting clean away some of the growths that have blossomed, which will encourage the new wood that by this time will be well developed. Upon the new wood the finest trusses of bloom are produced the following year. Roses of the kinds you name will send out strong arched growths of wonderful vigour. We have had *Crimson Rambler* growing in this way a most lovely object, the immense shoots all aglow with numerous trusses of bloom. You name one variety, *Miss Wilmott*, among your Ramblers. If this is the form of R. Indes known as *Miss Wilmott's* variety, then the treatment would be as above, but if the Hybrid Tea of

same name, prune back to four or five good eyes on each shoot.]

Rosa Woburiana and its hybrids.—Would you kindly afford some information as to the *Woburiana* Roses—new American hybrids? Are they hardy and free bloomers, and suited for north aspect, and what soil do they like best? The advertisement in last week's *GARDENING ILLUSTRATED* is the first notice I have seen of them.—**W. M. N.**

[These Roses have been frequently noticed in the pages of *GARDENING ILLUSTRATED*. They appear to be perfectly hardy, even those kinds hybridised with the Tea Rose withstanding the late severe frosts with impunity. As to being free bloomers, if you mean a profusion of blossom for a short time, then they answer to this, but they are not perpetual. As with the *Ayrshire* and *Evergreen* Roses, also the *Crimson Rambler* and its allied forms, after the first display there is nothing more in the way of blossom until another year. Nevertheless the tribe is a most valuable one for covering tree stumps, banks, rockeries, rustic bridges, and the like, but if employed for creeping over the soil some support should be afforded, such as a few large burrs or stones, the object being to prevent the growths being choked by weeds or Grass. These Roses are also most elegant objects when budded on tall hedge Briers, the long trails of growth reaching the ground in one season, forming perfect creeping Roses. For creeping, the type is by far the best, the exquisite deep grass-green foliage glistening as though varnished, and the growths freely studded with pure white blossoms in large clusters, the mass of golden stamens in the centre adding not a little to their beauty. Perhaps the next best variety is *Jersey Beauty*. This has very beautiful leathery foliage, shining as the type, but larger. The flowers are mainly produced in clusters of from two to four, but some are produced singly. The buds are charming, of a pale yellow colour, opening to single flowers some 3 inches across, and then of a pale lemon-white, with five bunches of golden stamens in the centre. This variety makes a handsome pillar Rose for conservatory decoration. It was produced by cross-fertilising the type with the Tea Rose *Parles des Jardins*. Another distinct and lovely kind is *Ruby Queen*. It is quite a departure from the type, the flowers being large, almost double, and of a most brilliant carmine colour, with the base of petals white. I believe this Rose will become extremely popular when known, the combination of colour being very striking and the growth vigorous, but not exactly prostrate. There are altogether some thirteen kinds, the novelties of this year in addition. The *Wicheriaea* Roses are without doubt a most useful tribe, but unless one has a real love for single Roses they will probably be disappointing. I have planted *Jersey Beauty* out as a single specimen, its main growths supported by strong stakes to a height of 3 feet, these allowed to tumble over on to the lawn, and most elegant was the effect. Even when out of bloom, as a sub-evergreen, it is a plant of much merit. Most of the tribe root freely from cuttings, and where they obtainable a light soil would be preferable, but if budded on the seedling Brier, then a good deep strong loam would be most suitable. Should you be seeking some hardy autumn-flowering climbing Roses for your northern aspect, you would not better the old *Gloire de Dijon* and some of its descendants, such as *Kaleirin Friedrich, Bouquet d'Or*, etc. Other good kinds are *Cheshunt Hybrid, Aimée Vibert, Jeune Desprez, Marie Robert, and Mme. Alfred Carrière*. All of these would grow from 10 feet to 15 feet and more in height. Others of a more lowly growth, say from 5 feet to 8 feet, would be *Mme. Abel Chatenay, Gruss an Teplitz, Grace Darling, Caroline Testout, La France*, and strong-growing Hybrid Perpetuals, such as *Filla Gordon, Ulrich Brunner, and Mrs. John Laing*.—**ROSA.]**

Photographs of Gardens, Plants, or Trees.—We offer each week a copy of the latest edition of the "*English Flower Garden*" for the best photograph of a garden or any of its contents, indoors or outdoors, sent to us in any one week. Second prize Half a Guinea.

The Prize Winners this week are: 1, Miss Lowther, *Compass Ash, Wickham Market, Suffolk*, for *Bowling Green at Compass Ash*; 2, Mr. J. Walters, 95, Gold Croft, *Yovil*, for *Cottage Back Garden*.

DWARF YARROWS (ACHILLEA)

HERBACEOUS aed alpine plants numerous through N. Asia, S. Europe, Asia Minor, varying in height from 2 inches to 4 feet; their flowers pale lemon, yellow, aed white, rarely pink or rose. Many of the cultivated kinds are too rampant for creeping with alpine aed rock garden plants; the dwarf kinds, on the other hand, come in groups for rock gardens or the margins of rock borders, and as edging plants. Most of the kinds grow freely and are easy of increase; but some of the higher alpine kinds are not very enduring in our open winters, and often in our gardens get somewhat "stagg" after a few years' growth, requiring occasional division and replanting.

A. ACERATIFOLIA.—A silvery-leaved plant from the mountains of Northern Greece, 4 inches to 7 inches high, with white flowers resembling *Daisy*; early in season. The leaves are narrow, crimped, and covered with white down. A neat and distinct plant, of doubtful hardiness, frequently damping off in winter. *Syn. Anthemis Aizoon.*

A. ALPINA (Golden Yarrow).—One of the showiest dwarf kinds, 8 inches to 12 inches high; leaves finely cut, flowers bright yellow; borne freely on upright stalks. A good plant for the rock garden, or for margins of borders. *Caucasus.*

A. AEGYPTIACA (Egyptian Yarrow).—A silvery plant, with finely cut leaves and pretty heads of yellow flowers. It is not hardy in all soils, but is so on well-drained sunny borders, flowering in summer and early autumn. *Division.*

A. CLAVENSIS (White Alpine Yarrow).—Dwarf and distinct, covered with a short, silvery down, flowers in summer a good white. It likes a light free loamy soil. Alps of Anetris; *division aed seed.*

A. HUTERI (Huter's Yarrow) has bright green foliage and pure white flowers. It likes a sunny part of the rock garden and grows well in common soil. Care should be taken to top dress, as it has a tendency to grow straggling.

A. REPERTUS (Rock Yarrow).—A pretty, white-flowered, and distinct species from Calabria, that begins to flower in May, much earlier than the majority of kinds. The small, green spatulate and entire leaves mark it as one of the most distinct of its race. The plant thrives best in deep, rocky soil. Height 4 inches to 6 inches.

A. TOMENTOSA (Downy Yarrow).—One of the tufted plants that help to form the carpets of silver whereon large *Violets* and *Gentians* display their charm: on the Alps, itself sending up flat corymbs of bright yellow flowers. It is a good plant for the margins of mixed borders, and also for the rock garden. European Alps, thriving in ordinary soil, and increased by division.

A. UMBELLATA.—In the more rocky portions of the rock garden, and for reestablishing quickly on old walls devoted more or less to alpine plants, this Grecian species is perhaps the most valuable of the silver-leaved Yarrows. Of rather woody growth and semi-procumbent habit, the plant soon forms a bush that is very striking when rightly placed. Rooting along its underside face the plant is increased to almost any extent. Height 9 inches. Flowers pure white.

A. NANA and MOSCHATA have like value to the above named for the rock garden, and some of the medium-sized kinds may also be used for bold effects.

The Mimulus.—The *Mimulus* is a bright showy blossom, whether one regards it from an indoor or outdoor standpoint, loving moisture, and blooming abundantly for weeks together. Pots containing old plants should now be taken in hand, and growth encouraged in every possible way; large roots may well be pulled to pieces and repotted, every scrap of roots with an "eye" to it probably making a plant. Those who have an old plants to fall back upon may at once make a start with sowing seed, which will grow in any light compost if simply scattered on the surface, watered, and covered only with a sheet of paper or a little Moss to preserve moisture. Young plants quickly grow, and will flower in June if attended to. For damp borders few things bloom better than do the *Mimulus*, and it is admitted that they are remarkably showy.—**LEAHURST.**

CANADIAN RICE (ZIZANIA AQUATICA).

The genus here cited is a small one, comprising only a couple of species or thereabouts. Usually the plants are regarded as of no horticultural worth, but surely the annual Grass that will attain to the dimensions shown in the accompanying illustration is worthy of consideration, from a waterside point of view, if nothing more. Indeed, we have too few of such bold, effective subjects. The growth of the subject of the illustration is, however, but the result of a few months, so that its rate of progress is somewhat rapid. The drawback to its permanent use as a waterside plant is, perhaps, due to its being of annual duration, though there is no reason why the plant may not appear in succeeding years from self-sown seeds. In any case, those having the management of water areas in private gardens or parks should not grudge the raising of a few seedlings each year, planting them early in their desired positions. This accomplished,

is tubular in outline. It is a distinct and pretty plant, and an interesting companion to the other members of this genus. Though frequently coming through our winters safely, it cannot be considered so reliably hardy as the better-known kind *O. tenuicum*. When planting the above, a well-drained chink where its roots may descend deeply in a free gritty loam in a sunny position, avoiding manure of any description, is the best position. The other species of this genus are

O. ZIBOIDEA, a very charming plant of biennial duration. Its flowers, which on large plants are abundantly produced, are of a rather pale yellow, and in favourable seasons seeds are freely produced. A warm, sunny exposure in the rock garden in deep gritty loam suits it well. In general habit the plant resembles *O. tenuicum*. Native of Southern Europe.

O. SIMPLICISSIMUM is a perennial species from Siberia, with terminal racemes of pale yellow flowers.

O. STELLULATUM is a variable species, having

short-lived in the border and requires care in any position. Shade should always be avoided in its culture, and the plants, if possible, so placed that the tufts of leaves may rest on a sloping ledge of rock, so as to keep fairly dry in winter; a soil of lumpy peat and equally lumpy fibrous loam, with sand very liberally added (quite a fourth part), and charcoal dust to a like amount. This and a raised, well-drained position in the rock garden will do as much as cultural aids can do for one of the best hardy plants. Its propagation is a rather slow business at times and must be done by means of cuttings, stripped off with a heel any time during May or early in June and inserted in very sandy soil (in pots preferred) without further ado. Never use a knife to a cutting of this plant. Given a thorough watering and left to dry for an hour, the frame should be closed and slightly shaded. With careful after-management the cuttings at this season root in about three weeks, and may then be potted off singly in much the same soil as recommended above.

The Canadian Rice (*Zizania aquatica*). From a photograph by G. A. Champion.

the plant will take care of itself. All the attractiveness of the above plant is in the well-marked leaves. The flowers are by no means attractive. It is a native of North America, and is known as "Water Oats," "Canadian Rice," etc. The grain is largely employed as food by the North-west American Indians.

THE GOLDEN DROP (ONOSMA TAURICUM.)

(REPLY TO H. BEECHAM SMITH.)

The best place for the Onosmas is, no doubt, a properly constructed rock garden, thoroughly drained, and in which provision is made for a good depth of soil, so that the plants may root strongly between the blocks of stone. The finest plant of *O. tauricum* we have seen was growing in good sandy loam mixed with broken grit, the plant being placed between large blocks of stone, near which the roots ramify and are kept cool and moist.

ONOSMA ALBO-ROSEUM is as yet a somewhat scarce plant in commerce. It has white or bluish-white flowers, which are drooping and inclined

flowers either white, yellow, or citron in colour. A native of Macedonia, growing about 6 inches high.

O. TAURICUM (Golden Drop).—This, the best known of the genus, is also the most worthy, and in good condition is a striking plant. The plant attains to about 15 inches high when fully grown, though rarely seen more than half that height. In habit it may be regarded as more or less an evergreen perennial, of a spreading, tufted growth, and from which in spring issue the flower stems. These are slightly branched, and furnish during May and June large clusters of drooping yellow and fragrant flowers that are singularly effective. Indeed, it is from the clear, pleasing yellow tone of the corolla that it has received the rather appropriate name of Golden Drop. This is undoubtedly one of the choicest of hardy flowers, better adapted, as a rule, for a well-chosen position in the rock garden than anywhere else. One of the very finest plants we ever saw was a dense, compact tuft fully eighteen inches across, and bearing many spikes of its golden-yellow flowers. Generally speaking, however, it is

A cold-frame or handlight is much the best for its propagation, and few hardy plants are worth more care in planting. Native of Caucasus. These, together with

O. PYRAMIDALE, a modern introduction from the Western Himalayas, constitute the known members of this genus.

ANEMONE VERNALIS (SHAGGY PASQUE-FLOWER).

ONE of the Pasque-flower division of the Anemone family, but very dwarf. The flowers are very large and shaggy, and covered with brownish silky hairs. It is a rare plant, and should be grown in some select spot on the rock-work, giving it good drainage and deep soil. It is a native of Norway, Sweden, and extreme northern countries, and also of very elevated positions on the Alps and Pyrenees, and is rarely seen in good condition in our gardens. It should, as a rule, be grown on a level spot on rockwork in deep, free soil, and be abundantly supplied with water in summer. Its flowers, which appear early in spring, are whitish inside.

NOTES AND REPLIES.

Clematises.—I wish to know the best Clematises to plant on an espalier between Roses, to hide vegetable plot from walk to garden facing south? Good old, established, proved sorts preferred. Must be hardy, to grow in north of Scotland.—O. A. M.

[You cannot improve upon the following: C. Jackmani, C. J. alba, C. G. Villacella alba, C. V. rubra, C. Henryi, C. Fairy Queen. These are quite hardy and abundant bloomers.]

Increasing *Lebelia cardinalis*.—I am anxious to increase my rather low stock of *Lebelia cardinalis*. How can I do so at least expense? If I could now get one or two large plants I could divide and multiply them, so as to be ready to plant out in summer.—M. A. M.

[Carefully break up the plants into single crowns with some roots attached, and pot singly into small pots, standing on a slight bottom-heat, but keeping the tops quite cool. In about a fortnight they will have started into growth, when they may be transferred to a cold-frame, keeping close for a few days. Gradually harden off and plant out when all danger of frost is past.]

Polyanthuses.—It may be that one of the reasons why so few people raise their own Polyanthuses is on account of the long time the seed is in germinating; but that is a feature which one ought not to lose sight of when purchasing the packet of seed. At any rate, one should give plenty of time for the seedlings to put in an appearance, and, with this in view, March is none too soon to sow for plants to bloom another year. I prefer to give them a start in the greenhouse, placing the pane on a shelf near the glass, subsequently pricking the plants into boxes and placing in frames as soon as the letter are available in May, finally planting them out in a partly-shaded border for the summer, where their needs as to watering are not likely to be forgotten.—LEAMURST.

Planting a rock garden.—I do not see any mention made of outdoor Cyclamens among the list of plants given to "Amateur" for the rock garden. I have grown them for some years under such conditions, and the beautiful foliage all the winter months makes them quite a feature. They went combining with other things because of the time when they are quite bare; but this is easily provided for, and nothing looks better with them than the variegated Periwinkle, allowing Creeping Jenny to cover them a little from summer sun. The shades range from white to crimson, and if the stones used are mossy flints, with an occasional hardy Fern, the tint is all the year round are of the most satisfying kind.—H. M. B.

Climbers for porch.—Would you kindly tell me what climber would cover a porch quickly? I want it to look well in time. The aspect is almost north and very sheltered, soil a gravelly loam. I have a blue Passion flower growing outside in a large tub, with a W. A. Richardson Rose (on a wall) I was thinking of putting them at one side. Would *Cobaea scandens* and *Campampelis*, sown now in a hot-bed and planted out in end of April, grow quickly enough? I will be thankful for your answer to these queries. The *Climanthe* and *Eucalyptus* grow splendidly here.—S. M. ALLEN.

[The *Campampelis* and the *Cobaea* are certainly among the quicker growers, but we doubt their being able to do what you require. It would be different if they were in strong plants now, and we are unable to suggest anything that will spring up more quickly. *Clematis montana* (pure white) is a beautiful spring-flowering plant, and quite hardy. The climbing *Nasturtium* are quick to cover, and so, too, the variegated *Lonicera aureo reticulata*. These are all good in their way, though we fear, even in your favoured district, the plants will not accomplish all you wish in the stated time.]

Lilies.—I have the following Lilies to grow for exhibition on June 10th: *Auratum*, *umbellatum erectum*, *umbellatum grandiflorum*, *pyrenaicum*, *speciosum rubrum*, *Thunbergianum atro-aquilinum*, *longiflorum giganteum*. I have potted them up and plunged them outdoors. Will they require forcing, or what is the best position and temperature for them to get them in bloom on June 10th?—P. F. L.

[You will have a difficulty in getting all the kinds named in flower on the 10th of June. To make sure of *L. speciosum rubrum* flowering at that date, it ought now to be in full growth, as its natural flowering period is early October or very late September. Some considerable forcing will therefore be required, and, to tell you plainly, we do not think you will succeed in the end. The varieties that should at once be placed in the greenhouse, if started, are *longiflorum giganteum* and the well-known *auratum*. The latter will require more warmth in a month's time. *L. pyrenaicum* will require to be kept quite cold out-of-doors, and in the

most shady position possible, as its natural flowering time is May. The forms of *umbellatum* and *Thunbergianum* named in your letter had best remain in the open for some time yet, but may require a little assistance later on. You must not in the meantime neglect them as to watering, etc. You had better write us again in a month, giving the progress of each.]

Plantain Lilies.—I have been a grower of these most useful and highly decorative plants now for many years, and can recommend them to the consideration of all who have to do with partially shaded gardens or positions naturally damp; not that they will not grow in sunny places, but in cooler quarters one has the advantage in keeping in good condition the beautiful foliage of *Fuckias*. F. *Sieboldii* I have had under a shady wall for several years, where it has assumed large proportions. It is the largest of the genus, has broad green leaves, through which quite a number of pale lavender flowers push their way. F. *grandiflora* has white flowers, sweetly scented; its best with me on a sunny border, being not quite so hardy as *Sieboldii*. F. *ovata undolata* is white and striped. F. *alba marginata* is bordered with white, and most effective. All are herbaceous, all easy to grow, and will be removed in April.—LEAMURST.

Single Dahlias.—Single Dahlias are now grown in many places where it is not convenient to grow the double varieties, mainly because the blossoms are peculiarly adapted to general decorative work, and perhaps also on account of the little culture they need to bring about a wonderful display of flowers in early autumn. It is not necessary, as is known, to save the tubers, as from seed sown in February one may procure a sufficiency of plants. Such being the case, those who have heated houses, and who do not care to go to the expense of buying plants in spring, should procure seed at once. A sowing is recommended in a shallow pan or box of light compost, covering the seeds thinly, potting each plant off separately when an inch or so high, giving them a little extra attention at this time by keeping them in a fairly warm temperature, potting on as soon as they are ready for a shift, placing them out-of-doors in well-prepared ground by the end of May. It is quite as easy to raise Dahlias from seed as any other half hardy annual, and considerably cheaper.—LEAMURST.

Sweet Peas.—No annual, unquestionably, within the last ten years has been grown more or thought so much of as the Sweet Pea. No one who has once grown it can be surprised at this, as, where quantities of blossoms are wanted two or three times a week in the summer for table decoration or other embellishment, what can compare with them for loveliness? Amateurs with small gardens find in them grace and beauty at little cost, yielding for weeks together flowers that harmonise with the decorations of any room, whether drawing or dining-room. I have just been sending my order for seed, and have been comparing the sorts catalogued now with what were known ten years ago, only five years since. What strides they have made! Some rows I sow with mixed seeds, but the greater part is sown in separate varieties, as, by so doing, one may cut them quicker and easily in their different tints. I believe in digging over the ground in November and incorporating with it a liberal amount of half rotted stable-manure, sowing my first batch of seeds in March, and the second lot a month or six weeks later. These come in fresh when the early ones begin to diminish. One may do a deal towards prolonging the flowering time of Sweet Peas by removing, day by day, blossoms that are spent and preventing seed-pods forming, which, if left, soon exhaust the plants.—DEKREV.

Petunias.—Petunias are as useful for indoor decoration in May as in June or July in the beds and borders, always giving one plenty of blossoms so long as right treatment is accorded them. That consists first in sowing seed in the greenhouse in February in a temperature of about 60 degs. in soil that is light and sufficiently drained. Pans should be prepared accordingly, filling them half full. Leaf-mould and loam, with a dash of rough sand, will meet what is needed, and the seed, being scattered thinly on the surface and watered in, partly

covering the pan with glass, will not be long in germinating in the heat stated. It is well to observe, perhaps, that young Petunias often damp off, and one should exercise care in applying water in the first stages, but when potted off and thoroughly established a liberal supply of moisture may be given. Petunias do not like too much restriction at the roots, and this being so, a removal into larger pots after their first shift cannot be deferred indefinitely without the plants showing by yellowness of foliage and a general breakdown that it is imperative. For pots it is well to encourage a somewhat bushy habit, and this is brought about by pinching out the leader when 4 inches or 5 inches in height, in order that side-shoots may more quickly form. Petunias are very shrew when planted in beds by themselves, or grow in vases on lawns, and where this is desired the next few weeks should see the seed sown. Where old plants have been kept the winter through there will doubtless be numerous shoots from which cuttings may be taken. These will strike readily in heat.—W. F.

Cutting down Clematis Jackmani.—Last spring I planted a Clematis Jackmani as a standard in herbaceous border, and wished my gardener to cut it down to within 6 inches of the ground in November. He also lately refused, saying as it was its first year he would leave it until the spring. Was he right, as I always notice instructions concerning this particular Clematis that it should be cut down in autumn? Mine bloomed well last summer. What is the treatment for a Clematis Flammea, and for a white *Jessamine* planted against south wall last spring and doing well?—T. M. D. II.

[It is doubtful whether the instructions to cut this variety down in autumn are always correct. The plant does not start into growth until early spring, and so long as the pruning is done by the end of February all will be well, so far as the plants are concerned. Flowering as it does on the younger or summer growth, pruning is a sort of necessity, or, at any rate, an assistance to larger flowers. As your plant is a "standard," we should have thought pruning back the head portion to be sufficient, but it will depend upon the plant and other items. In the case of a severe spell of frost, a "young plant" would be safer, we think, unpruned till severe weather was past. Clematis Flammea should be allowed frost-free, only removing the small wood. Hard pruning would for a year or so check its flowering, as the blooms issue from axillary buds of the past season's wood or growth. The white *Jessamine*, by which we imagine you refer to *I. officinale album*, requires very similar treatment to the last, removing plenty of the small wood and encouraging the most worthy rods or growth. This plant is better for some training, so that the sun may reach the shoots in due season. As the plant is doing well it will not be prudent to interfere with the practice that has been up to the present time adopted.]

Plants for shady border (*Pidget*).—There are many things that with advantage may be planted in such a border, which we presume you intend having thoroughly well dug up and manured prior to planting. You do not give its length or the class or depth of soil, items that have a value of their own in such a case. The following plants will, however, grow quite well under ordinary circumstances. Any of the Hepaticas, such as dwarf *Phloxes* as *ambrosia*, *verna*, *ovata*, *divaricata*, *Nelsoni*, and *atropurpurea*, *Campanula carpatia* and *turbinata*, *C. pumila* var., *C. Hendersoni*, *C. rotundifolia alba*, *C. glomerata dahurica*, any of the Peck-leaved *Campanulas*, also *C. Van Houttei*. Christmas and Lenten *Roses*, *Senecio Doronicum*, *Primula cortusoides* in variety, *P. rosea*, *P. denticulata*, *P. caschmeriana*, are all excellent. *Rudbeckia Newmanii*, *R. purpurea*, Day Lilies in variety, single and double *Pyrethrums*, *Gaillardias*, *Garman* or *Flag* Irises that would make a fine show alone, and such other *Iris* as *I. orientalis*, *I. missouriensis*, together with *I. Kämpferi* in variety, would do finely. Such early *Asters* as *Amellus* and the variety *bestrabicus*, *acris*, *lavigatus*, and a few select forms of *Michaelmas Daisy*s, particularly *Novae-Aegliae* var., and such as *densus*, *turbinellus*, and the lovely varieties of *cordifolius*. You may also find room for herbaceous *Phloxes*, for the constant shade would stand these in good stead, and a dozen choice or showy sorts would be welcome in their day of flowering. *Anemone japonica*, *A. j. alba*, *A. j. elegans*, would be all good, and not less so such *Spheeris* as *venusta*,

Arunene, palmate, and filipendula plena. *Monarda didyma* and *Stenactis speciosa* are very free and free flowering.

Early Sweet Peas.—Any scheme that will bring into bloom two or three weeks earlier than one is accustomed to obtain Sweet Peas should be adopted—if only on a small scale—wherever possible, and therefore the sowing of these beautiful annuals in the greenhouse now, and planting them out in May, after they have been duly hardened, is recommended. If neither greenhouse nor frame is at one's disposal, then a warm border, such as a south one with a wall at the back, is a useful place to get early bloom, and many are the bunches that may be gathered before the general flowers are ready. It is a good plan to sow the seeds thinly in pots, each variety separately, so that at planting out one may select the colours accordingly. In the meantime the ground

of soil, on this piece the turves (touching each other) in long lines; down the centre of each turf make a small channel about $\frac{1}{2}$ inch deep; in this sow the Peas and cover all with 1 inch or 2 inches of soil. We put oars in in February or early March, and they are planted out in shallow trenches prepared for them (when danger of frost is over), the earth drawn up well round them. The roots run into the turf, and all can be lifted together, with scarcely any check to the little plants.—L. T. F.

A SUMMER-HOUSE.

As no garden appears to be complete without a summer-house, and also a flagstaff, an endeavour has been made to combine the two, as shown in this illustration. This was put up last spring, and *Clematis*, *Henryi* and *Gladstone* planted to cover the posts, but, alas, the shoots were eaten

does this apply to the large forms of *robustus*, as *nobilis*, *Elwesianus*, a strong root of these being often 3 feet in diameter, like a hedge-stake. Lastly, carefully stake the spikes as they advance, and the wonderful display of flowers will amply reward anyone for his pains. The green-flowered species should be avoided—namely, *caucasicus* and *spectabilis*—as there is nothing beautiful about them. As showing the tenacity of life of the *Eremurus*, once a plant was sent me the crown and roots of which had been cut by a spade right through the centre. By placing the two pieces together, tying and carefully planting, a good firm root was taken out the next year.—M. P.

VEGETABLES.

* * CUCUMBER GROWING.

ANYONE who has a house, and can command 65 degs. to 70 degs. of heat at night, with a correspondingly higher temperature in the daytime, may start Cucumber growing at any time.

RAISING THE PLANTS FROM SEED.—Procure as many $\frac{3}{4}$ -inch pots as may be necessary, and sow one seed in each pot, and cover with about $\frac{1}{2}$ -inch of finely-sifted soil. The best soil to use is a sweet and light fibrous loam. Before sowing the seeds see that the soil is thoroughly warmed through by placing it in the house for a few hours. After sowing, put the pots in a propagating-frame, if there be one, if not, on a board over the hot-water-pipes. It is no use laying down any hard-and-fast rule as to what to do in this respect, because we all have to work according to our conveniences. See that the soil does not get too dry, and cover each pot with a piece of glass till the plants appear. As soon as the plants are well above the soil, give them all the light possible. Grew them on with plenty of heat and moisture till they have filled the pots with roots, and then they may be planted, or, if it is not convenient, they can be moved into 5-inch or 6-inch pots, and then planted out when they have filled those with roots.

PLANTING OUT.—Growers of Cucumbers who only require a few plants will find it much cheaper to buy them ready for planting. All have not Cucumber-houses specially built, so we have to put up with what we have in that respect. Suppose one has a span-roofed house, with a path in the centre, and, of course, the borders on each side, the first thing to do is to put 6 inches or 8 inches (or more, if it can be had) of good stable-manure, well beaten down, and then cover it over with about 2 inches of ordinary soil to arrest any ammonia fumes that may arise from the manure. Do this as quickly as possible after the manure has been put in. This manure will act as a hot-bed, and also drainage. The next thing to do is to get the soil for planting in, and the best for this purpose is a good sweet loam, not too heavy. If there is plenty of plants they may be put in 3 feet apart (at a greater distance apart if plants are scarce) along each side of the house. Put the soil in small mounds—an ordinary bucket full will be ample, to commence with—for one plant, and when it is thoroughly warmed through knock the plants out of the pots and plant without delay.

TRAINING THE PLANTS.—If there be some distance between the plants and the first training wire, put a neat stake to each plant and tie it to the wire. If Cucumbers are wanted quickly the plants may be stopped when they have passed the first wire, and the lateral growths will soon throw out plenty of Cucumbers, but if the plants are intended to bear for the greater part of the summer, the better plan will be to let them grow a considerable distance up the roof before stopping; this will add considerably to the strength of the plants. Pinch all the side-growths out between the base and the wire. All fruiting shoots ought to be pinched at one or two leaves beyond the fruit. Never let long shoots grow unstoppped, for they will be found to show fruit at the first two or three joints from the main stem, and in many cases none further, and therefore if allowed to grow on, a great deal of waste wood will be the result. This training is a very important item in Cucumber growing—it is Cucumbers that are wanted, and not leaves alone. Grow on as

A summer-house in a Surrey garden. From a photograph sent by Mr. W. Berrell, Sutton, Surrey.

should be prepared for an after sowing by well trenching it and digging in some manure, partly decayed. Not a few failures I have seen by manure being applied in too new a state in growing Sweet Peas, but, got on the ground now, any ill effects in this direction are obviated. Purchasers of seed for the first time will do well to obtain separate packets, and not "mixtures," as by sowing each variety separately one can gather the flowers of a particular colour quicker and easier, besides being more effective in the rows. That, however, is a point upon which a difference of opinion exists, but for a long show of bloom get some seed in st. onca.—LEAHURST.

—We are pestered with elegs. My gardener therefore grows our Sweet Peas as follows: Get strips of turf about 18 inches to 2 feet long, 4 inches wide, 2 inches to 2½ inches deep. Make a slight hotbed in frame, say about 5 feet by 4 feet. On the hotbed put 4 inches or 5 inches

off as quickly as they appeared. *Tropaeolum Fireball* was planted in its place, and soon grew and flourished profusely—this appears very suitable for such a purpose, as it leaves the woodwork clean in the winter. The position of the summer-house is in the S.W. angle of the garden, and affords a grateful shade during the heat of the day. W. BERRELL. Sutton, Surrey.

Growing Eremurus.—Transplant every year into good fresh soil. The plants may remain out of the ground, which does them good if covered over with half-dry Cocoa-nut fibre, but they should never be out of the soil after the middle of August. Choose a position free from draughts, and do not let the flower-spikes get frozen when rising from the centre in April and May. Never plant anything or dilute the ground for at least 3 feet on either side of a good root of *Eremurus*. Especially

quickly as possible with plenty of heat and moisture and very little air, and when the roots are seen on the outside of the soil add a top-dressing of 1 inch to 2 inches of rich soil, and continue to do this as the roots work through. When the plants are bearing heavily give them plenty of cow-mannure water and soot-water alternately. Syringe well twice daily.

The best and most suitable variety that I have found, and one which I have grown for the last four or five years, is a true strain of the "Rooford." The fruit is of medium size, good colour, and keeps fresh longer after being out than any I know, which makes it doubly good as a market variety. G BROCKLEHURST.

London House Nursery, Ruthin, N. Wales.

TOMATOES.

BEFORE these notes appear, growers of Tomatoes for market will have their plants well in hand, and, where one has almost unlimited heat and room, no one can question the advisability of an early start. Tomato growers, however, who have houses full of bedding and other plants are differently situated, and for those who cannot conveniently remove them before April or May to frames the present month is early enough to sow seed—in fact, I have had capital crops in July from seed sown in March. Any light, well-drained soil may be used to fill the pans, which should be kept as near to the heat and light as it is practicable, potting the plants off separately as soon as they attain a convenient size into good half-rotted turf and leaf-mould, shifting them again as soon as needed, until their last potting, which may be into any sized pot from 7 inches to 10 inches. The last-named size allows for filling up with manure and more soil as the plants require it in August, but for general use I have always found 8-inch pots large enough. At the last potting, three parts filling the pots with soil is recommended, as it is much better to add a little soil and stimulants as the roots require it than to fill up to the brim at the start; moreover, water and liquid-manure are more easily applied.

From a long experience, I am decidedly of opinion that many err in giving the plants too much root room at the start, swamping the roots, so to speak. I have had excellent crops from plants that were placed at the commencement in not more than 5 inches of soil, but were fed and mulched freely as soon as the first trusses of fruit had set. The system of training which I believe generally finds the most favour, and the one I have adopted, is the long rod, which admits of a sufficiency of light in the houses to other plants that may be growing, a state of things one cannot always report when most of the lateral growths are encouraged. The practice which is sometimes followed by growers who are over-anxious for the early ripening of fruit of outling away foliage in order that the sunlight may better reach the fruit, is one which I am convinced cannot be too often deprecated. Early ripening forsooth! I have seen rows of fine promising plants, with most of their leaves out away near bunches of fruit, when about the size of marbles—fruit that never afterwards made any size, and were certainly no earlier than plants let alone. Side shoots, which grow with surprising rapidity if left, should be removed every week, and the whole energy of the plant concentrated in the main stem, from which trusses of fruit proceed. In watering Tomatoes in the summer when fruit is setting, one should avoid giving cold water—lukewarm water and stimulants should always be applied if one desires the fruit to swell up quickly. Outdoor success in Tomato growing must to a large extent depend upon the season, but where one has a warm wall there one may reasonably anticipate a crop. The best and strongest plants should, however, always be selected in preference to any that show signs of weakness, and this point cannot be emphasised too much. Frequently the plants that are left in the seed-pans are those which are considered good enough for outside growing, but the season is often half over before any signs of fruit are visible. Locality, too, is all important. In the south and west of England much success often follows outside planting, but in the north it is still regarded in the light of an experiment, and this must be taken into consideration in planting. Often it is asked when outside planting must be done

It is a question easier asked than answered, as in the south one may plant several weeks earlier than the grower in the midlands and the north. Not before May, and only then when the weather is such as to admit of plants being transferred to the open; a week or two longer in the house or frame is often the best, but one is bound to observe local traditions. I have said nothing about varieties, as of late years numerous excellent sorts have been sent out, but I have still a good opinion respecting Sutton's Earliest of All, Early Ruby, and Trephry. The first named produces an excellent crop in an average season on outdoor wells.

WOODBASTWICK.

SOWING PEAS.

WITH the advent of March, we may safely sow Peas of the Marrowfat section in quantity without any fear of defective germination, provided the seed is good. To keep up a constant succession sowings every fortnight or three weeks will be necessary, and a good rule to follow when ground is plentiful is to sow occasional rows when those previously sown have come through the soil. All may not, however, be able to spare ground enough for such frequent sowings, and those who are limited in this respect may get a good succession by sowing thinly on well-prepared ground at intervals of three weeks, provided a good selection of varieties has been made. Much has been written during the past few years on the value of this sowing, but the lesson has not yet been well learned by all growers, and there is still a tendency to forget or overlook the fact that the Pea is a naturally branching plant, and the method which obtains of thick sowing is a foolish one, for the plants choke each other from the start, and the crop is very steepling. There is no necessity, however, to rush to the other extreme, and the heaviest crops are produced from seed sown in deep flat drills broad enough to hold three rows of seed placed diagonally at from 2 inches to 3 inches apart, varying the distance slightly according to the natural vigor of the variety that is being sown. On light soil flat deep drills are a necessity almost throughout the season, and these should be thrown out with a spade to some 5 inches below the surrounding level, returning 3 inches of the soil thrown out of the drill after the seed is sown. The old V-shaped drill drawn with the end of a hoe is the worst possible form, for in such a drill the seed rolls in a mess to the bottom, and it is the Peas sown in this way which die off at the bottom in dry weather just before podding. Where the rational method of thin sowing is carried out, every precaution must be taken not to sow bad seed, and time spent in looking over the seed before sowing and throwing aside any that is defective is well spent. There are many good varieties of Peas suitable for present sowing, and each grower will have his special favourites. For good all round quality Dr. Maclean, though an old variety, will still be found hard to beat. Criterion is also specially good, while Gradus will probably be found one of the finest selections ever sent out, and those who are looking for the highest possible quality in a second early Pea can make no mistake in getting this fine variety.

TURNIP-ROOTED CELERY (CELERIAC).

ONE very useful vegetable for the season, when a large variety is needed and not always obtained, is Celeriac; yet how little it appears to be known or grown. I think if those who have to supply a household with as much variety as possible all the year round were once to try this they would soon realize its value, coming into use as it does in the winter months, when a change is needed from the general run of roots and green stuff. Celeriac is a distinct dish from the ordinary Celery when used as a vegetable, or it can be used as a salad, besides the culture is no more difficult than that of Celery. A very good plan is to sow the seeds in a pan and place in a gentle heat early in March, as this vegetable requires a long season of growth. As soon as ready the seedlings can be transplanted 2 inches apart into boxes of sandy soil. Before the plants get too crowded in the boxes, plant them out 6 inches apart into a bed of fine soil out-of-doors in a sheltered place, where a little protection can be given when required. In June select a piece of light rich soil that has

been cultivated, and put the plants out on to this on the level in rows 2 feet apart and 18 inches apart in the rows, selecting those plants with only one crown if possible. Those with side shoots, if used, must have these taken off. From this point the plants will require plenty of water and keeping free from weeds. As soon as the plants get thoroughly established the soil should be removed from round the sides of the plants, the damaged leaves removed from the bottom of the plants, and all side roots must be kept cut away, leaving those that go down straight or nearly so. This seems very important, and the roots do not appear to grow naturally to the desired shape without it, and which, I believe, accounts for this vegetable not being cultivated as much as it should be. In August draw a little firm soil around each plant, bearing in mind to give plenty of water in dry weather. In October lift a few of the roots and store in sand, leaving a few leaves in the centre of the plant, or the roots will soon become worthless. The remainder of the crop can be left in the ground and covered with surrounding soil for use later on. E. W. C.

NOTES AND REPLIES.

Pea Harbinger.—In the issue of GARDENING ILLUSTRATED of Feb. 15 a correspondent recommends the Pea Harbinger, which had an award of merit from the Royal Horticultural Society last year, at the same time saying there is another Pea of the same name. Would he kindly let me know where the first is to be had, and oblige?—SIRIVA DORAS.

[Messrs. Sutton and Sons, of Reading, are the introducers of the Pea bearing above name, which received an award of merit at Chiswick on June 20 of last year. It is said to be a great improvement on American Wonder, and, as our correspondent stated in our issue of February 15, the variety only grows to about 9 inches in height. The previous variety bearing this name was raised by Mr. Laxton, and received a first-class certificate from the Royal Horticultural Society in 1872, but it is now very rarely met with.]

Sowing vegetable seeds (A Beginner).—The Dwarf Erfurt Cauliflower, if it be of the Snowball type, should be ready for cutting early in June. But to have it so the plants should be on a warm border. You do not tell us whether you live south or north. Walcheren Cauliflower is seldom good. Early London is better for succession. That, the Autumn Giant, and Self-protecting should be sown middle of March in a warm place outdoors, and well protected from birds; or else in shallow pans or boxes stood in a frame. Autumn Giant should be ready for cutting early in September, and the Self-protecting will follow it. To have very early Leeks, sow seed at once in a shallow pan or else in two or three pots. Such plants would be fully a month or more earlier than those raised outdoors. If you make up a little dung hot-bed for a frame, allow the first heat to be over before you place the seed-pan into it. Keep the pan near the glass, and give air at the back when growth begins.

Crimson Globe Onion.—Though not so large as Cranston's Excelsior, bulb of the dark red variety being about 1 lb. each, yet this is a very fine Onion for late use, as it keeps an admirably. I had a few bulbs of this capital variety sent me during the winter, and I find them still to be hard as nails. These were grown on deeply-trenched and well-manned soil, having been, as is now common practice with our leading Onion growers, raised from a sowing of seed made under glass in midwinter, the plants later being dibbled out into the open ground. I crossed Ailes Craig with the large Crimson Globe a few years since, and obtained as the product a handsome rose-coloured sample which I named Surrey Rose. Crimson Globe is a great advance on the old Blood Red Onion.—A. D.

Cabbage Defiance.—There are several diverse Cabbages of this name in commerce, so, unfortunately, seedsmen will so freely give to each of their varieties or stocks names differing from what other traders call them. For that reason it is possible to buy six Cabbages from diverse seedsmen under various names, yet find eventually they are all the same. The partitioner Defiance Cabbage I refer to is Cannell's. I grew it last year for the first time, and not only found it to be remarkably true, but of such a perfect medium-sized form

that it got the highest praise from all who saw it. These plants were autumn-sown, but planted out in the spring. It makes an equally superb variety for sowing in March or April for autumn cutting. It also sprouts remarkably freely in the following winter, when it gives a wealth of small heads.—A. D.

Parsnips.—These may now be sown at any time when the ground is fit, though there is no immediate cause for hurry in the matter, and it is far better to wait a few days, or even weeks longer, than to sow on ground in bad order. My practice is to grow Parsnips on ground lately occupied with Celery, adding no manure, and digging to the full depth of a good spade and breaking down all lumps of soil in the process. On very heavy soil it sometimes happens that the necessary degree of looseness requisite for the production of good and shapely roots cannot easily be obtained, and in such a case a good plan to follow is that adopted by those who grow for show—viz. to dibble holes at set intervals, which may be filled with fine soil into which the roots must go straight. This of course increases labour, and is only advised by me for extreme cases, but if done, the soil for filling the holes should not be too light, and it

texture. It is quite equal to that of the best of the tapering-rooted varieties. Seeing that fine bulbs from an early sowing on a warm border can be had so early as the middle to the end of July, it is a great gain to all who like Beets to be able to secure a stock in this easy way. Sow seed in drills 12 inches apart early in April. Give good ground, and thin the plants out early to 6 inches apart. Growth then is rapid, and bulbs form very quickly.—A. D.

Value of lime—Lime, when given in small quantities and at proper intervals, proves of great assistance to most crops. If more lime were used and less manure for a few seasons the purifying properties would soon be realised, and ground that has practically become manure-sick would be brought again into a sweet, fertile condition. Many are shy in using gas-lime, but they have yet to learn the value of this when carefully applied. To guard against any accident resulting from its use, ground should be dressed with it several weeks before plants or seeds are put in, and if left exposed for some time previous to digging it in much of its strength will be exhausted. Several patches were treated in this way a month ago and the lime is still on the surface; but it will be dug in

TREES AND SHRUBS.

THE BLADDER NUT (STAPHYLEA COLCHICA) FOR FORCING.

This is one of the best of shrubs for sorry forcing, being equally free flowering as *Dentzia gracilis*. It comes into bloom early without much fire-heat, and has the advantage of having very ornamental foliage of a bright glossy green. The flowers, which are pearly white, are borne in clusters, and the plant blooms freely when small. It may be had in fine condition in 5-inch pots, the flowers being useful for vases or other decorations indoors, or for making up into bouquets. It makes a good companion for the *Dentzia*, *Prunus*, *Lilac*, and other shrubs that are forced early into bloom, and it will flourish under similar treatment. The main point to aim at is well ripened wood, and the only way is to encourage early growth, which must be ripened off without any covers check. After flowering it should be removed to congenial growing quarters to perfect its growth, and be gradually inured to more air as the sun increases in strength, until it can be plunged in the open air in some sunny position where it can fully perfect its growth, when it will flower abundantly for years, even in small pots, if well supplied with liquid-manure. In the open air it flowers early in the summer, being quite hardy and preferring partial shade. T.

The Pearl-bush (*Exochorda grandiflora*)—This is one of the most lovely of spring-flowering shrubs. It is allied to the *Spiraeas*, in its synonymous with *S. grandiflora*. It is grown on walls, but it may be grown as a bush in the more sheltered parts of the garden, ordinary soil sufficing. It is a native of North China, the large, pure white flowers being produced a few together in racemes, the tender green unfolding leaves making a charming contrast. A good bush of it is a pleasing picture, growing several feet in height and of dense habit.

The Snowdrop-tree (*Halecia tetraptera*).—One of the most beautiful of flowering trees in its season is *Halecia tetraptera*. Introduced so long ago as 1756, it is still by no means so extensively grown as its beauty warrants. It is perfectly hardy, and, given a rich, open soil, and abundant moisture, makes a charming display in April. I have a tree, every year crowded with flowers, which is 15 feet high and more in breadth. The popular name of Snowdrop-tree is a particularly appropriate one, for the pure white pendent flowers, which thickly stud the old wood, have a close resemblance both in shape and pose to those of our native Snowdrop. They are borne in clusters of three or four on short stalks. The specific name refers to the four-winged fruits. The tree is deciduous, the leaves just pushing after the flowers have expanded. The species is a native of South Carolina, etc., and likes more especially the banks of streams and other moist situations.—F.

DR. CHARLES STUART.

We regret to have to announce the death of Dr. Stuart, who has done so much for our gardens in giving us many of the beautiful forms of rayless Tufted Pansies that we now have. One of his favourite flowers for hybridising was the Pansy, which since 1854 he has been trying to improve. In 1874 he crossed the old *Viola cornuta* with the Pansy, and thus raised many beautiful forms, a dark blue one named Georgia being one of the best at that time. We grew six of these seedlings in the R.H.S. Gardens, Chiswick, where a trial of *Viola* was then being made, and to each of the six a first-class certificate was awarded. Dr. Stuart set to work to raise rayless kinds, and the result was the beautiful *Violetta*, the first of the series of rayless Tufted Pansies. Characteristics of these rayless forms are their sweet scent and perennial habit. Since that

The Bladder Nut (*Staphylea colchica*) as forced. From a photograph by G. A. Champion.

should be made fairly firm before the seed is sown, or it will settle too much later on; if of too light a nature the young plants will suffer in dry weather. Only a few seeds should be sown at each station, and the plants must be thinned to one as early as possible. For general purposes and ordinary soils Parsnips may be sown thinly in drills about 14 inches apart, thinning the young plants to 10 inches apart in the rows, and this will give ample room for the development of roots of a useful size. If big roots are wanted more room must be given, but these are wasteful and their growth should not be encouraged. I prefer the hollow-crowned Parsnip (of which there are excellent selections in the market) to any other, though the Maltese is also a variety of excellent quality.—T.

Crimson Globe Beet.—Those who like Turnip or round-rooted Beets, and all who have gardens should grow some, and will find in a good stock of the variety known as Crimson Globe, a sample a long way superior to that of the old Egyptian Turnip-rooted, as originally introduced. The improved variety tells in its own way of the great advances that have been made through constant selection, and how much we owe to seedsmen for their great care in seeking to obtain the very best. This Crimson Globe Beet has flesh of the darkest and of refined

et the first opportunity, and as the ground will not be required until well into March there is little fear of any harm resulting to the next crop, which will be Onions. Two small cart-loads were spread over a piece of ground which measures 20 yards by 40 yards.

Brussels Sprouts.—Much is written yearly about the various types of this much-esteemed vegetable. It is questionable, however, if there are more than two types. All appear to belong to one or the other. The extra large-buttressed sorts may suit the market man, because they fill the bushel more quickly. For home use the small firm sprouts obtained from plants raised from imported seed are preferable. All must admit that for flavour and tenderness the small sprouts are much the better. The greatest mistake people make in growing Brussels Sprouts of any kind is sowing the seed too late. The first week in March is late enough for even the latest batch. The middle of February is chosen for the earlier batch. Well dug land in an open position and allowing the plants plenty of space to develop their leaves strongly are the secrets of success. An early and matured growth is absolutely necessary to obtain a full crop of close firm buttons. It is not to be expected good results if the sprouts are not formed before the end of September.

time he has raised many other charming forms. To him we also owe the beautiful *Aquilegia Stuarti*, the result of a cross between *A. Witmani* and *A. glandulosa*. He also devoted some attention to the Globe Flowers, crossing the European and the American sorts with encouraging results.

GARDEN WORK.

Conservatory.—All plants require sufficient pruning to put them into proper shape. This is generally done after flowering in the case of hard-wooded plants. Soft-wooded things are pinched during growth to obtain the necessary balance of the various parts to secure perfect specimens. *Fuchsias* are pruned at this season or earlier to improve the shape, and the strong shoots are pinched when they break away and get in advance of the general growth. This work should be done in a conservative spirit. A well-grown *Fuchsia* is a beautiful object in the conservatory, either in a pot or planted out in the border. In a large house *Fuchsias* may be planted out, and by a little pinching made to assume a pyramidal outline, 10 feet or more in height. The best compost for *Fuchsias* is equal parts of good loam and leaf-mould, or old manure made sufficiently porous with sand and charcoal dust. The charcoal gives brightness to the flowers and deepens the green of the foliage, at the same time hardening the growth. If *Luoulia grisea* is grown as a bush in the border it should be pruned rather hard back after flowering. *Thrips* are partial to the foliage, and if there are any in the house some will be found on this plant and should be destroyed, either by vapouring or sponging. The repotting of greenhouse plants, especially those which flower in winter, generally takes place now or during next month. *Pelargoniums* are, in some early varieties, in forward bud. We generally have some in blossom by Easter. The aim of most gardeners is to get things early, and there is usually a brisk demand for flowers, especially white flowers, at Easter. The most useful plants to grow for that season are *Arum Lilies*, *Trumpet Lilies*—especially *longiflorum*, which is more reliable than *Harrisii*. *Dentzia gracilis* and *D. Lemoinei* are very useful; the latter named makes a neat bush somewhat larger in all its parts than *gracilis* and flowers freely. Both may easily be propagated by cuttings of the young shoots in the hot-bed. When well hardened off, plant out for a couple of years to get strong. White *Azaleas* and white *Rhododendrons* are indispensable at Easter. Other indispensable flowers are white *Tulips*, *Lily of the Valley*, and *Pheasant-eye Narcissus*, positions ornate. The double-flowered variety will not force. All plants which require support should have stakes given early, so that they may be more naturally placed—i. e., the plant and the stakes have grown to each other, and not look so stiff as when placed late.

Stove.—All fine-foliaged plants, especially those which grow best in very fibrous materials, should be repotted now or shortly. Unless very carefully drained there is a tendency to blocking in the drainage, and all plants are the better for being overhauled and put right for the season. The fibre, too, in the soil decays and closes up the pores of the soil, and when this state of things is noticed it is time to repot even if the pots are large enough for the plants. *Euphorbia splendens* is a curious though not a handsome plant generally, but when in bloom it is very interesting, and the flowers are useful for working up, especially for ladies' sprays and coat flowers. To make the plant flower freely the growth must be well-ripened by cooling down and exposure in summer. Then, when brought back to the stove the flowers burst out all over the spiny branches. *Plumbago rosea* is a rather interesting plant when in flower in winter. *Pentas* roses and its white variety are even more valuable for cutting. *Gloxinias* are easily raised from seeds sown now in light sandy soil and covered with a square of glass. The majority sow these fine seeds too thickly, and they are weakened in a small state before they are large enough to do anything with. When they are too much crowded it is better to move them in small patches to other pans, and separate them later when they are larger. Never throw away the small plants, they may

have the best flowers. Night temperature now 65 degs. to 68 degs. Ventilate a little when 80 degs. is reached.

Rose-house.—This house will be most interesting now. The growth alone of the *Teas* and *Noisettes* in its freshness is attractive. If *Roses* are planted in beds and borders under glass it is important the beds be well drained and the soil be of the best loam and some old manure, but the two should be so blended that the manure does not predominate anywhere. Manure is necessary, hot if too near the roots in any quantity its effect is not good. For *Roses* in pots, or in the borders under glass the manure and loam should be mixed thoroughly some time before using. When the roots are well-nourished and comfortable mildew is less pronounced and insects give less trouble. *Roses* like fresh air, but it must not come with a rush to create cold currents. The syringe also must be used, but the water should be soft and pure, and of the temperature of the house.

Ventilating fruit-houses.—The time is at hand when the man in charge of fruit forcing-houses must increase his activity and observation. It will not do to put on a lot of air to over time in looking round again. Short cuts will not do. The outside conditions of the weather must be closely studied, both as regards fires at night and ventilation during the day. Air should be put on in small quantities to meet the rising thermometer. It is bad to permit a house of *Grapes* or *Peaches* to get very hot and then let in a rush of cold air to reduce the temperature. Meet it as it rises and then the young growth will not suffer from the fluctuations. Close early enough in afternoon for temperature to rise to 85 degs. at 90 degs. with a stratified atmosphere—that is the time to do a little extra forcing, when the sun will do the work without the drying influence of the fire. Fires should be managed with care and judgment. A good stoker in a large establishment is a treasure, and is worth good wages, for the saving in fuel will be considerable, and the damage done by overheated pipes reduced. Red spider in a viney or Peach-house is often caused by careless firing. Always keep a close watch upon the dampers in the chimney.

Window gardening.—Cuttings of *Campulus* for hanging baskets will strike now, or old plants may be divided, and should be potted in a mixture of loam, leaf-mould, and sand. *Meeubryanthemums* are pretty plants in a sunny window. They associate well with *Cactuses*, and will do well with the same treatment, neither involving much trouble in winter beyond keeping dry and safe from frost.

Outdoor garden.—February is an excellent month for transplanting all kinds of hardy flowers. Trees and shrubs also can be moved with safety when the weather is open and the soil in good condition. Land that was trenched up in autumn and exposed to the weather will now be in good condition for planting. There are a few hardy flowers which seem to resent disturbance. Among these are *Madonna Lilies*, *Alstromerias*, and *Paeonies*, but these form the exception to the general rule. Many things may be left on the same spot till they quite change their character. This is especially true of *Phloxes* and *Pyrethrums* which should be transplanted and divided often if fine flowers are wanted. One wants to be always working among one's flowers to be able to treat them in the best manner. We generally leave a part of our *Carnations* on the ground two years, because the old plants throw so many flowers which are good enough for cutting. But for really good blooms young plants are best. The late frosts must have lifted little plants partially out of the ground, especially where recently planted. This will be the case with *Violas* and *Pansies*, and in the drying winds such plants soon perish if not seen to and pressed into the earth again carefully. A few seeds of the hardiest annuals may be sown now for early bloom. The *Virginian Stocks* are very bright and will grow anywhere, even in the hard gravel path. Put in cuttings of *Delias*.

Fruit garden.—Those who have any grafting to do should secure scions of the right kinds and lay them in a shady position where the earth is damp. It is of no use trying to put new heads on old, worn-out trees, but where there are vigour and health in connection with

an inferior kind, regrafting will be the right course to follow. Most of us are growing far too many kinds of *Apples* and *Pears*, especially of *Autumn Pears*, which come in about the same time, but more attention might be given to very late kinds. One of the best *Christmas Pears* is undoubtedly *Glen Moresan*, but it wants to be planted in good well-drained land, or if the subsoil is not good, plant on stations and keep the roots out of the bad stuff—in fact, the same course should be adopted with all late *Pears*. *Winter Nalis* and *Bergamote d'Espereen*, though small, are good and reliable, and both do well on the Quince. The mistake often made with trees on the Quince and other dwarfing stocks is in not giving sufficient nourishment. The Quince loves moisture and must be well supported, and there must be no digging about the roots. There is no better late *Plum* than *Coe's Golden Drop* for dessert, and it generally bears well in all forms, though it is worthy of a wall. Still we have had some wonderful crops on pyramids and standards in the open. *Nuts* and *Filberts* should be pruned now.

Vegetable garden.—As soon as the frost is out of the soil and the surface has become dry and mellow, seed sowing and planting may begin. Of the former, *Paranips* and *Onions* should be got in without delay. Plenty of *Peas* and *Beans* should be planted to meet all demands likely to arise, and there is never any glut of *Peas* early in the season. Early *Peas* sown now will not be much behind those started under glass, which, if well hardened, may be planted out, ridges of soil being drawn near them, and the sticks placed thereto at the same time will afford shelter. The early borders will now be under crop with such things as the following:—*Potatoes*, *Peas*, *Logpod Beans*, *Horn Carrots*, *Radishes*, *Lettuces*, and a few early *Cabbages* for the first crop. The last-named will probably be a small early kind, and may be planted much thicker than is usual with main crops. We generally plant *Ellis's Early* as one of our first earlies about 10 inches apart, and as soon as they begin to grow freely a string of *Raffia* is passed round them drawing the leaves up loosely to hasten the hearting. When the hearts have formed they are cut and the stems pulled up, and the ground prepared for dwarf *French Beans*, or some other crop. Plant *Seakale* cuttings and sow *Asparagus*. Sow *Mustard* and *Cress* indoors at present. E. HOBDAV.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

March 10th.—Re-arranged Herh-beds, dividing the herbaceous kinds, and put in cuttings of *Sage*, *Lavender*, *Rosemary*, etc. Removed exhausted green crops, manured and treched land. Took up more *Rhubarb* and *Seakale* for forcing. This is the last we shall move. Later supplies are coming forward in the ground. Divided and replanted a lot of *Rhubarb* to increase stock. Swept and rolled lawns.

March 11th.—Repaired Box edgings. Turned over gravel walks and added a little fresh gravel where necessary, and rolled down firmly. Some little extra work has been done in the shrubberies in reducing the sizes and otherwise improving the contour of some common things. Planted *Anemones* and *Ranunculuses*. All bulbs for conservatory after flowering are hardened off in cold-pit and then planted out.

March 12th.—Potted the last batch of *Lilium longiflorum*, and *auratum* will come on cool. The earliest *Lilium longiflorum* is now in bud, and is wanted at Easter. *Spiraeas* of the herbaceous kinds are better than usual with us this year, and are flowering well. One of the best single *Narcissis* for forcing is *Horsfieldi*, and the price is not excessive. Put in more *Lobel* cuttings in boxes to save space. *Azaleas* are abundantly in bloom now. Large *Lilac*-bushes also are charming.

March 13th.—Moved the early-stocked *Chrysanthemums* to cold pit; will be grown cool and freely ventilated. We are still putting in a few cuttings of certain kinds, and shall do so from time to time. Our best cuttings have been obtained from plants which were planted out specially for cuttings, and not permitted to flower. Pruned a lot of *China Roses*. We want more stock, and most of the cuttings have

been planted firmly in a shady border. We want more of these for grouping.

March 14th.—Carrotion borders and beds have had a sprinkling of soot and a turn over with the fork, and the plants will be set out at the first favourable opportunity. Sowed Spinach, Chervil, and more Lettuces. Tied up Lettuces in frames following Asparagus. Some of the best and heaviest Lettuces we ever had were grown on a mild hot-bed after Asparagus. Placed sticks to early Peas.

March 15th.—Replanted Globe Artichokes that were potted up in the autumn. The plants will be sheltered for a time till established. Potted off Tomatoes intended for outside planting. Put in more cuttings of Tree-Carnations in a small hot bed frame. Planted more Potatoes of several kinds. The sap is rising freely now, and we are doing a little grafting, more especially Apples. Pricked off tender seedlings of various kinds.

LAW AND CUSTOM.

Overhanging branches of trees.—I am living in a terrace house and my tenants' My neighbour has an Elm-tree in his garden, and the branches overhang my garden, keeping out the sun. The tree was there before my tenancy commenced. Have I a right to cut off those branches overhanging my ground? My neighbour objects to this being done.—J. M.

[You may, if you choose, cut off any portion of the branches that overhang your land. The fact that you are only a tenant of the garden you occupy does not affect the question, but you must, of course, remember that if your garden and your neighbour's garden are held by you and him of a common landlord, and the landlord takes sides with your neighbour or prevents the severing of the branches of the trees, he may possibly give you notice to determine your tenancy. But your legal right to sever such branches is unquestionable.—K. C. T.]

Death of tenant—future of tenancy.—The tenant of my cottage, who was a widow, died just before Christmas, and her son came out to the funeral, and afterwards locked up the place and went away without saying anything about the tenancy. I wrote to him, telling him that his mother's things could remain until February 11th at so much a week for demurrage, but reserving the right of the garden from Christmas for the incoming tenant. I have received no reply from him. Can he hold the cottage until Lady Day, when the year ends? I was to repair the house after the 11th of February. Can I claim the key? The son has partitioned off the kitchen, leaving either one or two doors. Can he take the partition down again?—MARRIE GARDNER.

[You do not describe the nature of the tenancy, although as you say the year ends at Lady Day, it may be presumed it is a yearly tenancy. Whatever its nature may be, it devolved upon the son on the death of his mother, and, in the absence of any express contract to the contrary, he can continue to hold the cottage until his tenancy is determined by a proper notice, but, of course, he will be responsible for the rent in the meantime. This means that neither you nor your incoming tenant have any right to the garden, and that you cannot charge for demurrage, although you are entitled to rent. You cannot demand the key on February 11th, as if the son intends to keep on the tenancy until it is determined, you cannot enter without his consent. If the partition erected can be taken down without injury to the rest of the premises, the son may take it down before quitting.—K. C. T.]

Enclosing waste places at side of road.—I have some tree-hold land, separated from a parish road by a hedge. Between the hedge and the road there are some vacant places, one in particular where my entrance gate formerly stood. Can I straighten my hedge over these vacant places, or, rather, replace the hedge by a wall, as the hedge is overshadowed by trees on my land and so grows badly? If not, to whom do these vacant places belong, and how many feet from the road can the parish claim? The surveyor of the district council has ordered me to lop a large tree that grows on one of these vacant spaces, and only 2 feet or 3 feet from the road.—ELM.

[This "parish road" is evidently a highway, and the highway extends the whole width between the fences, unless a part of it lies on a high bank or in such a position that the public have not and could not acquire the right of passage over that part. With this exception, the whole width between the fences of an enclosed highway forms part of the highway. Apparently the hedge is crooked, but that gives you no right to straighten it by taking in ground over which the public have acquired the right of passage. If you want to straighten the line you must proceed the other way by

cutting back the hedge or wall so that it stands wholly upon your own land. The soil of the vacant places may belong to you, and, in the absence of any evidence to the contrary, the soil of the road up to the middle of the way will belong to you, but you can only see it subject to the right of the public to pass and repass. This reduces your ownership to a point that is almost nominal, but it preserves to you the property in the tree in question and in any minerals under the road.—K. C. T.]

A sub-tenant's notice (Bob)—For seven years you have been the sub-tenant of a Grass field under a farmer, paying rent yearly. In the end of January last you paid him the yearly rent, and he told you he wanted the field and you must give it up at once. You refused to do so, no notice to quit having been given. On February 15th he turned your cattle out of the field. You have manured it, and you ask if you can claim for the manure. He could not legally turn your cattle out of the field, and he committed a trespass in so doing, as you are entitled to keep the field until the expiration of a proper notice to quit. Your remedy is by action for trespass and breach of covenant for quiet enjoyment. A solicitor will quickly get you ample compensation for the trespass, and you can keep on the field also.—K. C. T.

BIRDS.

Death of Bullfinch (Hildport).—The internal organs of this bird were in good, healthy condition, showing that the feeding was not at fault, although it is not usual to give Bullfinches Millet seed. The sample of Rape seed sent is the right kind for these birds, being what is known as summer Rape. Where the large black Rape is used, it is well to scald it to remove its acidity. The immediate cause of death was rupture of the heart, in the region of which was a large clot of blood. Possibly the heat of the room overcame the bird. Bullfinches are very susceptible to a high temperature, which affects them injuriously.—S. S. G.

Canary eating its feathers (T. P.)—Your bird appears to be very late in moulting, but there is, however, a great difference in the way in which Canaries go through their moult, for while some ched their feathers very quickly and without trouble, others have great difficulty in getting their new plumage. It is no unusual thing for a bird to cease singing at the moulting season. It is very difficult to deal with a bird that has got into the bad habit of picking out and eating its feathers, but if your Canary merely nibbles at the feathers that it has already cast in the process of moulting you should provide it with something to peck at, such as a piece of outle-fish-bone, to afford it healthful amusement, avoiding sugar and sweets of all kinds. There should not be any festers at the bottom of the cage at this season of the year; you are probably keeping your bird too warm. A tonic in the drinking water, such as a rusty nail, or a small piece of sulphate of iron, the size of a small Pea, will impart strength to the system and get the moulting over quickly. The diet should consist of Canary seed, German Rape, and Linseed, while a pinch of Maw-seed should be given once a week.—S. S. G.

Tomtits in garden.—Your correspondent, "S. S. G.," is not quite accurate about the Tit family. Five of them build in holes—viz., the Crested, Great, Blue or Tom, Cole, and Marsh Tits. Those who have to do with are the Great, Blue, Cole, and Marsh. The Great and Blue build in holes of trees, boles in walls or buildings, pumps, letter-boxes, or boxes put in trees for them to nest in. Of this latter kind I have several which are occupied every year by Blue Tits. I never knew them nest before the middle or end of April—the same date about as the Great Tit. Both kinds as frequently lay ten or even twelve eggs as seven or eight. The Cole Tits build generally near the ground, in a wall, or mouse-hole, or dead stump, or Sand-Martin's hole, and have generally ten to twelve eggs by the middle or end of April. The Marsh Tit always makes the hole for itself, like the Woodpecker, choosing a rotten railing or pollard Willow; in fact, any tree with wood rotten or soft enough to bore into. The nest, of a very meagre kind, is at the bottom of the hole.

perhaps some 6 inches or so down. The eggs are generally eight; I never found more in a nest. The 1st of May is about the time the Marsh Tit begins to lay.—H. G. TOMLINS, *Burton-on-Trent.*

CORRESPONDENCE.

Questions.—Queries and answers are inserted in *GARDENING* free of charge if correspondents follow these rules: All communications should be clearly and concisely written on one side of the paper only, and addressed to the Editor of *GARDENING*, 87, Southampt-on-street, Covent Garden, London. Letters on business should be sent to the Postmaster. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper, and not more than three queries should be sent at a time. Correspondents should bear in mind that, as *GARDENING* has to be sent to press some time in advance of date, queries cannot always be replied to in the issue immediately following the receipt of their communication. We do not reply to queries by post.

Naming fruit.—Readers who desire our help in naming fruit should bear in mind that several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. The difference between varieties of fruits is, in many cases, so trifling that it is necessary that several specimens of each kind should be sent. We can undertake to name only four varieties at a time, and these only when the above directions are observed.

PLANTS AND FLOWERS.

Cyclamen (Torquay).—The plants have received a severe check at the time of the forming of the buds, by being over dry at the root, probably, or other cause. This cannot now be remedied. Few plants require more constant care and not a little skill to cultivate with success than do Cyclamens. Some weak stimulants as the buds form is very helpful, and any labour is repaid by the fine show of flowers in winter time.

Cuphea ignea (J. J. S.).—This is the name of your plant, so far as can be determined by the wretched fragment sent. It is not possible to be sure of the identity of any plant from so microscopic a bit, which is rendered worse by being packed in dry paper and crushed to nothingness in the post. The plant is a greenhouse shrub of a foot or rather more high, and as easily grown as a Fuchsia. Indeed, you cannot do better than treat it in the same way. The plant is a native of Mexico.

Common Moas (Rovin).—You may obtain what you desire by placing an order with some of the leading seedsmen, though we doubt very much their being able to supply it direct. We think the better plan would be to introduce a quantity of the Moas now in a quite fresh state, and endeavour to establish it by these means. We are not quite clear as to what kind you refer to by "common Moas," as so many varying forms are common enough each to its own most favoured locality.

Treatment of Cyclamens (Town Gardens).—After Cyclamens have done flowering they should be watered as carefully as before, but as the leaves turn yellow the supply must be lessened, till when all the leaves are off they may be stood in a frame, or even in a sheltered spot out-of-doors, giving but very little water. Then, about midsummer, shake clear of the old soil, and repot, using the soil in a frame in order to ward off heavy rains, as they will not couch water to the roots, and the plants will moist. After this, as the leaves develop, more water will, of course, be necessary, but avoid over-watering Cyclamens in any stages of growth.

Raising Saxifraga Borreriana from seed (H. Becham Smith).—By sowing the seeds as soon as ripe in very sandy loam in a well-drained pot or pan. The seeds germinate very indifferently. If you possess plants that will now flower, your best plan will be to try and secure your own seed, as it is hardly purchasable. Cover the seed very thinly, place the seed pot in a saucer of water to keep the soil moist, with only a minimum supply of water above. Cover the pot with a sheet of glass. Careful division of the plants is a more sure and certainly a much quicker way of raising stock.

Planting climbers to arch (M. N. L.).—As your proposed wire arch is to be but 6 inches wide, it is useless to plant two Roses or other climbers on each side, as one would only crowd and starve the other. Nine inches is narrow for anything. In any case plant but one Rose on one side and Clematis Jackman on the other. By far the best place for Jasminum nudiflorum is on a south wall or house side, where in open weather it will bloom all the winter and cover a large space in due course. A good white hardy climbing Rose is Climbing Devonshire, so also is Climbing Niphetos. Roses and other climbers may be purchased in pots, and can be planted at any time up to the end of April. Still, best plant so soon as possible.

Climbing Roses for wires on south aspect (Querrin).—Of the list you submit the four best kinds as permanent would be Gloire de Dijon, Climbing Bella Siebrecht, Climbing Kaiserin Augusta Victoria, and W. A. Richardson. The next four, to be afterwards cut away if necessary, we would recommend Marechal Niel, Climbing Niphetos, Climbing Cramoisie Superieur, and Climbing Malmaison. Climbing Niphetos and Marechal Niel are very tender, and would need careful protection in winter. If you could bring down the growths near to the ground, so as to cover with soil and litter, you should be able to succeed with these kinds, but the four first named would certainly furnish the best good and full south aspect are Cheestnut Hybrid, Gloire de Dijon, Alceas Vibart, Flora, Aglaia, Follie's Parquet, Charles Lawson, Mme. Isaac Perle, Monsieur Desir, and Kaiserin Friedrich.

Planting Gladioli, etc. (Myrrh).—If you plant Gladioli in Britain you should at once they should bloom at the time you name, while the later planting at end of April should also bloom in September. If you plant the gladi-

VEGETABLES.

SOWING PEAS.

So abundant are good wrinkled Marrow Peas now that no one need sow any of the inferior hard round varieties. But it is seldom that justice is done to these Marrow Peas, as most of them need more room than round herd-seeded Peas do. If these wrinkled Peas are seen after they have been sown for a week or so, it will be found that they have doubled in size, because the moisture of the ground has caused them to swell up large, thus showing that they will produce strong plants needing ample room. Now the customary rule in sowing is to draw drills with a hoe 3 inches deep, and so formed that the base of the drill is quite narrow, thus causing all the Peas to run together quite thickly when sown. That is bad practice. There are two better ways. One is to make the bottom of the drill as broad as is the top with the face of the hoe, thus enabling the Peas to be more widely distributed, or else to draw ordinary formed drills side by side, placing the Peas along each drill, from 2 inches to 3 inches apart, the tallest Peas being those most widely placed. In the single broad row the same distance should be observed. The result is an immense saving of seed, for one half the usual quantity sown more than suffices, the plants are stronger, they branch freely, are remarkably productive, and suffer far less from drought or trips than do plants that stand thick in the rows.

We habitually, for rows of 3-foot Peas that are to crop lying on the ground, make a pint to sow 100 feet length, and if to be staked, 120 feet. Many persons very wrongly sow a pint in 40 feet of drill and are proud of the dense, solid appearance of the rows when the plants are a few inches in height. But when in bloom they find so many flowers go blind that many pods are deformed, and that the pod crop is after all, as compared with the promise of the plants, a very poor one. If sowings be made at once on warm borders of such dwarf varieties as Chelsea Gem, English Wonder, The Daisy, or American Wonder, those may be sown rather more thickly, as there is more risk of harm, by birds, and the plants will not have to endure such dry hot weather as later sown Peas will.

Varieties that are to crop in July and August should always have the soil for them deeply worked, plenty of manure buried down to encourage roots to go down out of the hot surface soil, and when staked have a thick mulch of animal manure placed along on each side of the rows. Should mildew appear, a gentle spraying with Bordeaux-mixture will help to save the plants from its ill effects. A. D.

NOTES AND REPLIES.

Planting grown-out Onions.—"W. S." does well to point out the advantage of using them as he has done in a recent issue. I have done this for many years, and have found them keep me going for two months when old ones were over and autumn-sown ones had been killed by frost.—J. CROSS.

Herbs—In every garden, large or small, some herbs should be grown, for they are needed in every household, and often during the

course of a year. Thyme, Sage, and Mint, if not always to be had in a green estate, are useful when dried; the same remarks hold good about Parsley. Tarragon and Fennel have each their special use. Planting may be done during this month, and where arrangements can be made, a bed should be set apart for the special growing of herbs, so that those whose particular business it is to see to the wants of the kitchen may always know where to find the herbs that are wanted.—WOODBRISTOCK.

Carrots.—Where a hot-bed has not been made up for these, a sowing may now be risked on a sheltered border with a southern aspect. As this sowing will only be wanted to give a few weeks' supply in small bed or plot will suffice, and if sowing in drills be preferred to sowing broadcast, these need be no more than 8 inches apart. Drills must be drawn very shallow, as Carrot-seed fails to germinate when buried deeply, and seedsmen are often blamed for the grower's error in this way. Small early varieties should be selected for this first outdoor sowing, and, to give an immediate succession to these, Market Favourite is a good variety.

Cold pits, value of.—It is surprising how useful cold pits are during the winter months. I have been cutting Veitch's Self-protecting Broccoli from October 6th to February 22nd. I usually sow once, the middle of March, and as the plants get large enough to draw, keep planting out, and thus get a succession. I plant 2 feet apart, and keep the plants growing all the summer. At the approach of frost they must be looked over, digging up any you think the frost are likely to spoil, and placing in a cold pit. These can be used as required, and in November, or at the sign of a sharp frost, dig them all up and treat the same as the others, putting a little soil in among the roots. Do not let any remain out in the open because the hearts are small, as they will grow larger in the frame and come in when vegetables are scarce. Give plenty of air when favourable and mat up the frames in sharp weather. I may mention that I cut a nice heart of Adam's Early White Broccoli to-day (February 26th), so with me the two have made a good succession.—K. R., *Rajingstoke, Hants.*

Best kinds of Broccoli and Cauliflower.—Will Mr. Hobday kindly tell us as soon as may be in his note on the current week's work in gardens what are the varieties of Broccoli and Cauliflowers which we ought to sow so as to get a long succession as possible of these vegetables? I do not ask for the names of novelties, which may be all that is claimed for them, but of approved sorts which a modest gardener, not in search of experiments, would do well to grow. His list will, I hope, include Veitch's Autumn Giant and Veitch's Self-protecting, which for some years have done well with me.—W. F. MERRIS.

[The kinds of Cauliflowers I grow are Veitch's Forcing, just a few for early work, Early Erfurt, Walcheren, and Veitch's Autumn Giant, and I have often thought during a dry, hot summer that the last was the most useful. I sow Autumn Giant in the autumn for use in August, and again in spring for late use. As regards Broccoli, I grew Veitch's Self-protecting Autumn Broccoli the first season it came out, now many years ago, and have grown it since, and consider it one of the most valuable vegetables grown. By making two sowings, one

in April and the other in May, a supply can be had till long after Christmas if the plants are lifted before injured by frost and planted in a deep pit, or, better still, in a cool-house. The difficulty with Broccoli is to get the plants true. If one buys Broccoli seed in the ordinary way it is no uncommon thing to get two or three sorts out of one packet of seed. The only remedy is to get the seeds from the most reliable source. The following half-dozen kinds will give a good succession: Snow's Winter White, this is sometimes difficult to get true, but is very useful when true; Early Peanaroo; Perkin's Leamington, to my mind one of the best Broccoli grown when true; King of the Broccoli (Daniels); Veitch's Model, and Sutton's Perfection. If I might add another kind or two as alternative sorts I should name Cooling's Matchless and Knight's Protecting; the last is an old kind, but splendid when true.—E. H.]

Growing Cucumbers and Tomatoes.—I should be much obliged if you would tell me if I can raise Cucumbers from seed, and grow them in a lean-to greenhouse without artificial heat, but which gets great sun-bat, even now, as it is against a south wall, and the whole garden slopes to the south? I have no hot-bed as yet. (Could I raise the seed in pots? If so, what is the proper compost? I have never grown Cucumbers before, but have seen them doing well in a greenhouse like mine in pots or boxes, the plants trained up near the glass. I should be grateful for any hints as to these or Tomatoes in the same way.—E. A. M. W.

[You can raise Cucumber plants and grow them very well in an unheated greenhouse if you will wait a little longer, until the season is more advanced and the temperature more settled. At present, even in the warmest positions, if we get some days quite warm, we get some cold ones and nights. To raise Cucumbers you need general good sun warmth. For that purpose better wait until the middle of April. Then sow nine seeds at equal distances apart in 5-inch pots. These should have in them an inch of drainings, then be filled with a compost of turfy loam, leaf-soil, old well-decayed manure, and sand well mixed, not necessarily fine. Bury each seed half-an-inch in the soil, water the pots, then stand them in a box 2 inches deeper than the pots. Place the pots into it, and cover up close with a large piece of glass. Shade with thin paper if the sun is very strong. The plants, if the seed be good, should be up in about a week. Sow Tomato-seed and treat it in exactly the same way, but put eighteen seeds into a pot and only just bury them. When your plants of Cucumbers are well up and showing the third leaf turn them out of the pots and shift them singly into pots half the size, and grow them on near the glass roof to make them sturdy. Then get pots 10 inches broad at the top, or boxes 12 inches by 16 inches, fill with good soil in which turfy loam is two thirds, the rest being well-decayed manure. Put one plant into each pot, or two into each box, and stand those near the glass roof so that the plants are 18 inches apart. You must fix, 10 inches from the roof, wire or wood strips to tie the plants to. Make the soil pretty firm. As growth follows pinch out shoots without fruits and preserve those which have fruits. Treat Tomatoes just the same, but they can be 14 inches apart only, and must have every side shoot hard pinched out, but preserving the leaves. See article on Cucumber growing in coming issue.]

PLANTS AND FLOWERS.

MOSCHOSMA RIPARIUM.

THIS, which comes from South Africa, resembles when out of bloom a green-leaved *Salvia*. The flowers are small, pinkish-white, with purple anthers, and borne, as may be seen in our illustration, in terminal panicles. It has been shown frequently of late at the Mill Hall, its flowering period beginning in December and lasting till well into the new year. It is best to increase it by cuttings every year. The plants should be cut down immediately after flowering and given warm, moist treatment to cause them to break into growth. When the cuttings are about 3 inches long they may be at once put in. It will thrive under the same conditions as *Salvia splendens*, and will be found a very useful plant in the dull season for the conservatory and greenhouse.

NOTES AND REPLIES.

Old corms of Cyclamen.—Mr. Frank Rich may be interested to learn that many growers retain their *Cyclamen* corms for several years before finally discarding them, I being among the number. There seems to be an impression that they will not flower so strongly or so freely as young corms do; but this is quite erroneous, as I have some at the present time carrying over one hundred blooms each, and for quality are not surpassed by those produced by young corms. There comes a time when the corms do become exhausted and worn out, but until that stage is reached my advice is, by all means keep them, and by generous treatment, in addition to adopting proper cultural methods, such will each year reward their owners with a nice floral display.—A. W.

Wiring Camellias.—Will you please let me know how Camellia buds are cut and wired for sale? I find it very difficult to cut off the bud without destroying the small leaf close to it which forms the bud for the next year, and there may be two buds and a leaf all close together. If the stem of the branch with bud is cut off, then the bud for next year is lost, so it seems to me best to cut only the bud and preserve next year's growth.—CAMELLIA.

[The blossoms are not cut off usually in the gathering, but taken in the fingers, slightly gathering up the petals, and twisted off. To do this successfully, take hold rather firmly and towards the base of the petals, and a fair twist will do the rest. The wiring is quite a simple matter. Take a bloom in the left hand, gather the petals rather closely up, and with a rather fine stem-wire pierce the petals through, passing the one end out on the other side. The point of piercing should be $\frac{3}{4}$ inch or so from the base, perhaps rather more. A second wire will be required, and should be passed through on the opposite side to the first one. This will give you four wire ends to bend down for stem. Prior to drawing down the wires thus, take a piece of cotton-wool, well moistened, and place up close to the base of the bloom. This assists in keeping the flower fresh, and the wires retain it in position. With the wires drawn down, a little binding wire will keep the stems together. A little practice will put you in the right way, and doubtless a bloom or two will be spoilt in the learning, or you will be fortunate.]

Pefarguniums for winter flowering.—I am anxious to have my conservatory (which is heated with hot-water-pipes) bright with *Geraniums* throughout the winter and spring. Will you tell me in what months I ought to take cuttings so that one lot of plants may commence to flower in November and the second lot in February? My plants have been flowering well all the winter up to February, but have now stopped, and are growing very tall.—SPRING.

[For producing plants for winter blooming, the best way is to take stout cuttings in February. When rooted, grow them on as hardy as possible, shifting into $4\frac{1}{2}$ -inch pots before they become pot-bound, keeping them close to the glass and giving a abundance of air. At the beginning of June stand them in a sheltered position in the open air on a bed of ashes, pinching the growths when of sufficient length, and assisting the roots with liquid-mauure as soon as the 6-inch pots, which will be large enough for the plants to flower in, are becoming pretty well filled with roots. A good fibrous loam and some coarse sand suit them well. Keep all summer trusses of bloom picked off, and remove into a temperature of 50 degs. early in October. Their somewhat root-bound

condition will induce flowering better than larger pots at this season. Even during the winter a gentle current of fresh air must be given in open weather to prevent the plants becoming drawn.]

Cyclamens not flowering.—Would you kindly let me know why my *Cyclamens*, sown in the summer of 1899, will not flower? I send you a specimen. The corms are healthy; the foliage of the sample is certainly weak, but they are not all like this, though some indeed have only thrown up four and six leaves. Is it solely a bad strain, and would you advise me throwing out the lot, as room is an important item with me? Are they likely to bloom next year?—F. P. O.

[The young plant of *Cyclamen* that you have sent is perfectly healthy, and the reason of your

of direct sunshine and cold currents of air; indeed, what would be regarded as a snug little house is the best place for them. A little fire-heat will soon be needed, and under such treatment the young plants will quickly make their appearance. When large enough to handle pot them singly into $2\frac{1}{2}$ -inch pots, using a mixture of loam, leaf-mould, and sand. The month of February is a good time for potting them off, and if the temperature of the house is kept from 50 degs. to 65 degs. they will grow away freely. A gentle bedewing with the syringe in bright weather is very beneficial. By May or June they should be ready to shift into 5-inch pots, in which they are to flower. The pots

Moschosma riparium. From a photograph by G. A. Champion.

plants not flowering; is that they have been grown too slowly. It is true that many cultivators obtain good flowering plants in about 18 months from seed, but this is where they are grown in quantity, and not associated with other things, as is necessary in many places where a miscellaneous collection of plants is cultivated. In giving briefly the routine of successful *Cyclamen* culture you will be able to see if you have fulfilled all the requirements. The month of August is a very suitable time for sowing the seed, which is best done in shallow pans, as there is sufficient room to avoid overcrowding, which at any stage is very injurious. At that time the temperature of a greenhouse is sufficient, but they should be placed where clear

should be well drained, and a suitable potting compost is two parts good fibrous loam to one part of leaf-mould, with a liberal sprinkling of silver-sand. When potted, stand the plants on a good bed of ashes in a cold-frame, situated, if possible, where the midday sun does not shine direct on it. The plants will need to be shaded, and a light eyringing three or four times a day is very beneficial. Watering must be carefully done, as an excess of moisture at the roots is very injurious. As the plants develop, a little weak guano-water about once a fortnight will be of great assistance. By September the plants should be ready to take into the greenhouse, and some of them will soon commence to flower. We should certainly advise you not to

throw your plants away, but to treat them as above detailed for young unflowered plants, and trust that next autumn you will have nothing to complain of regarding their condition.]

ROSES.

ROSE GLOIRE LYONNAISE.

I REMEMBER when this Rose was introduced by M. Guillot in 1884 it was described as a yellow

yellow, it is true, but the expanded flowers change to almost pure white. During very intense heat, such as we experienced last summer, an exquisite tinge of delicate pink pervades the petals, adding much to the charm of the very large blossom. I am afraid there is no prospect of obtaining seedlings from this Rose, as it yields no pollen grains, neither will it produce seed. It is a splendid late-flowering garden kind that should be very sparsely pruned in order to obtain the best results. Its long growths, quite devoid of prickles, should

at back from 1 foot to 2 feet, and even more. Like all the Hybrid Teas it succeeds admirably on standard Briers, but objects to the Manetti. If wanted for the garden, the seedling or cutting Brier is the best stock for it, unless obtainable on own roots, which is better still. As it roots readily from cuttings, it should not be difficult to procure in that form. It is a first-rate kind for pots—not forced, but grown cool—and would also make a fine pillar Rose for greenhouse supports. ROSA.

NOTES AND REPLIES.

Rose Papillon.—What kind of a Rose is Papillon? I have only seen it in one Rose list, and there its qualities are described as very good.—H. F. MATTHEWS.

[This is a very pretty Rose, having curious twisted petals, which doubtless suggested its name. The colour is carmine-rose, shading to deeper salmon, a very beautiful tint and rather uncommon. It is one of Nabonnand's many beautiful seedlings, this raiser having introduced the variety over twenty years ago.]

Pruning Rambler Roses.—On receiving vigorous Roses of the Rambler type from the nurseryman, which have three or four very long shoots about 4 feet or 5 feet, how much should these be pruned the first season after planting in February or March in my newly-made Rose-bed?—H. F. M.

[Climbing Roses of the Rambler type are best cut back to about half their length the first year. This will encourage the basal eyes to break, so that good growths are secured which the following year, if left intact, will give a fine display of blossom.]

Rose Marechal Niel.—I venture to send you a little of the surface soil of a deep bed for a Marechal Niel Rose in our small conservatory. It is infested, with insects, and the plant is evidently suffering, the new leaves withering when only just opened. I shall be grateful, indeed, to know by what means I can destroy the pest? I have been in the habit of piling Tea leaves round the stem. Could that possibly help to breed this vermin?—H. MATHIE.

[The only thing you can do is to clear out the soil in which your Rose is growing, adding, in its place, some good loam and a little manure, and taking care that the drainage is good. No Rose could do well in such poor rubbish as you send.]

Pruning Banksian Rose.—I have a fine specimen of a yellow Banksian Rose. East aspect, trained on house; it flowers sparingly. In February it is trimmed back. Is this right?—SWALLOW.

[It is not surprising that your fine specimen blooms but sparingly, seeing that you prune it in the month of February, and by so doing cut away all the flowering wood. The best time to prune is directly after flowering, merely removing old and worn-out wood. The spray or small twiggy wood should be preserved, as this usually produces the most blossom. Where plants are of a good age and have been neglected, a considerable reduction of the number of growths should take place, so that light and air can penetrate and thus harden the new wood; but above all things retain the young growths in their entirety, excepting of course any that are produced late in the year, and are thus soft and pithy. These should be cut clean out.]

Hardy dwarf Roses.—In my garden are steps leading from the lawn to the path on the terrace. At each side of the steps are walls about 3 feet high, and I should like to plant something along the sides of the walls to hide them a little—something not to exceed 2 feet high, fairly sturdy. Aspect, full south; soil light, sub-soil stiff loam; position exposed. Should like Roses, but am doubtful as to their suitability for the position. Would China Roses be suitable, and, if so, what are the best compact-growing, hardiest varieties? If not suitable, what would you suggest for such a position? Hybrid Perpetuals succeed fairly well here.—YORK.

[You do not mention the width of the border, but we presume it will be a foot wide at least. If so, and the soil is deeply dug, you should be able to grow some very good Roses upon such walls. As there will doubtless be a slope, you must take care that the plants are watered during dry weather, and a mulching of short manure would be of considerable assistance, commencing in May and allowing the mulch to remain till autumn. Plants from cuttings would be by far the best for your purpose on the wall. If cut back hard each year they would not exceed the limit of height, although we do not suppose there would be any objection to the Roses rising above the top of the wall; in fact, when viewed from the terrace, they would have a very nice effect. In preparing the soil, break up the subsoil and put in a layer, 3 inches or 4 inches thick, of cow-manure. This should be about 18 inches from the surface. Some nice loamy soil should be afforded to each plant when

Rose Gloire Lyonnaise. From a photograph by Miss Willmott.

Hybrid Perpetual. That was before the Hybrid Teas had become famous as a separate class. There is no doubt it is a true Hybrid Tea by the stiff growths and Tea-like blossom, but, unfortunately, there is no fragrance. It has not quite the ever-blooming character of the true Tea. It is said M. Guillot obtained this Rose as the result of three consecutive crosses, and judging from some recent introductions it would appear that this method of procedure has much to recommend it. One cannot say Gloire Lyonnaise is a yellow Rose. The buds, so suitable for buttonholes, are a clear, soft lemon-

be retained fully 2 feet long, and you longer if desired; indeed, I can advise its use as a pillar Rose, and against a 5-foot or 6-foot wall or fence it is quite bappy. The illustration faithfully portrays the beauty and effectiveness of this Rose as a garden variety, and the mode of pruning adopted in order to obtain a towering mass of blossom is also most commendable, especially when the plants are given a suitable background.

When Roses as Gloire Lyonnaise may be made more effective by pruning some of the front growths, say to 7 inches or 8 inches, and those

planting. The following would be an excellent selection to choose from: Chinas: Armoza, Common Pink, Mme. Laurette Messimy, Mrs. Bosanquet, Fahvier, White Pet. Polyanthas: Perle d'Or, Oloire des Polyantha, Mme. E. A. Nolte, Eugenie Lamesch. Hybrid Teas: La France, Grace Darling, Camcena, Viscountess Folkestone. Teas: Marie d'Orleans, Marie Von Houtte, Medes, Mme. Lambert, Papa Gontier, Maman Cochet (both white and crimson.)

GARDEN PESTS AND FRIENDS.

Insects in Cucumber-bed.—I am sending in a small bottle some ants or small insects which congregate on the Cucumber-beds in the hot-house in millions. I will fast obliging if the editor would kindly suggest some means of killing them?—PLAS IBA.

[The small insects you find on the Cucumber-beds are mites. You do not say if they have injured your Cucumber plants. If they do not I should not trouble about them; if they do, you might spray the beds with paraffin emulsion, or some similar compound, such as "Abel," or you might scrape or skim off the surface of the soil and burn it. Boiling water, as you have found, is very efficacious in killing the mites.—G. S. S.]

Muscel scale on Apple-trees.—Will you kindly inform me what this is on the enclosed Apple twigs, and can you give me a recipe to get clear of same, as I have several young trees badly infested with it?—A. H.

[The twigs from your Apple-trees are attacked by the muscel scale (*Mytilaspis pomorum*), one of our commonest scale insects. The shoots you sent are so badly infested that I should advise you to cut off and burn any that are in a similar condition, and dress the others with paraffin emulsion. If the shoots can be reached it is best applied with a stiff brush, and it should be well rubbed in. If on account of the size of the tree they cannot be treated in this way, they should be sprayed with the same mixture, taking care that every infested part of the tree is reached by the insecticide. The emulsion may be made as follows: Boil $\frac{1}{2}$ lb. of soft-soap in $\frac{1}{2}$ gallon of water, and when it is quite dissolved stir in (but not over the fire) 1 gallon of water. Work it through a syringe until it becomes of a creamy consistency, then add nine times its bulk of soft water. Mix it thoroughly with the syringe, and it is fit for use.—G. S. S.]

Black ants destroying Cyclamans.—Would you kindly inform me about these Cyclamen bulbs in the next issue of your paper? They have been riddled by black ants, which have attacked two or three other Cyclamen bulbs in the same house. As far as I know, there was no defect in them at all before the ants attacked them. Is it not a very unusual proceeding on the part of these insects? What can I do to prevent them damaging the other bulbs other than dusting them with Tobacco-powder? The ants are not in any great number as far as I can find, and entirely confine themselves to the small part of the house where the Cyclamens are.—GEOFFREY HARRALL (REV.)

[I have never heard of ants attacking Cyclamens in this way before. The best remedy is to find the nest and destroy it. This is easily done if the nest can be reached by opening it and pouring in boiling water. This is best done when all the ants are in for the night. If the nest is in such a position that this is impossible, means should be tried to pour paraffin-oil or dilute carbolic-acid into it. Sometimes the nests are made under the floor of a greenhouse, and the ants find their way between the stones or bricks of the floor. When this is the case, a piece of well-kneaded clay or putty, well worked down on to the stones or bricks, should be formed into a kind of cup round the hole by which the ants enter—this should be filled with paraffin-oil, which will gradually trickle down into the nest and kill the ants. If this be not practicable, trap the ants in saucers of beer and sugar, or treacle, or with pieces of sponge soaked in treacle with a string tied to them, so that when covered with ants they may be dipped into boiling water. Bases not thoroughly cleaned may be used in the same way. If each pot be set on a small saucer inverted into a larger one partly filled with water, the ants will be prevented from reaching the plants.—G. S. S.]

As many of the most interesting notes and articles in "GARDENING" from the very beginning have come from the readers, we offer each week a copy of the latest edition of either "STOVES and GREENHOUSES PLANTS," or "THE ENGLISH FLOWER GARDEN," to the reader of the most useful or interesting letter to the Editor published in the current week's issue, which will be treated thus.

GARDENING UNDER DIFFICULTIES.

A VICARAGE just below the church, standing on a gravel bank, exposed to every wind that blows, facing rows of cottages, with a background of furnaces, and, beyond, the unseen along-bound Solway shore. If the wind were set enough to check the enthusiasm of an amateur gardener, he might well be forgiven for yielding to the heightening influence of smoke and dreary landscape! It was, however, these very conditions that seemed to make flowers a necessity of cheerful life, as surely as it is the possession of flowers that leads me to contribute some experiences for the encouragement of other equally unfavoured amateurs. The weekly perusal of GARDENING from cover to cover makes a man long for a sunny clime and a congenial soil, but it does not always encourage gardening under difficulties. Some years' experience of stum life, never without a flower and its influence, has taught me that, with patience, the selection of suitable plants, and perhaps contentment with a less luxuriant growth, no one need despair of surrounding home with Nature's choicest gems.

At the outset, the obvious difficulties to meet were wind and drought, due to the exposed position and gravel subsoil, and, in a less degree, the absence of shade. Open trellis-work and edgings of fine wire netting gave more shelter than any form of wall or close paling. Hedges of Privet, Beech, and Buckthorn have taken more kindly than anything else to the south-western from the sea, with the exception, perhaps, of common varieties of Salix. These, in turn, win some shelter from plantings of common and Golden Elder. Trees and shrubs, however, as yet make little headway. The flower-beds are more grateful, and, though they may lack the setting of beautiful surroundings and leafy backgrounds, they are instinct with memories of Surrey, Westmoreland, and Lancashire more favoured gardeners. I sometimes wonder what plants from far Fochabers or from the heights of Rochet du Naze think of their new surroundings, where furnaces outnumber trees and selfishly exclude the distant glimpses of Criffell's sunset radiance or Skidaw's heights. Well, whatever their thoughts may be, they coolly fulfil their mission, and strive to live an elevating influence just where they are told.

First comes *Scilla sibirica*, with its blue flowers, never so appreciated as under the smoke-stained sky; then Aconite, Crocus, and Lent Lily, some thrusting their way through masses of *Antennaria tomentosa*, with its close silver foliage, and *Aubrietia purpurea* and other alpine which find a home and shelter on the rockeries. Snowdrops do not come up a second year, Narcissi also fail. The Turban Lily (*poniponium*), from a Surrey garden, flourishes and blooms soon after Easter. *Lilium tigrinum* and candidum in sheltered corners resist the wind and smoke amazingly.

After the spring hulas have gone to rest the Polyanthus and Primrose struggle to make a show, but summer drought and sun are too much for them. Wallflowers and the common Columbine, the former with masses of *Myosotis* near them, make a display of which no garden need be ashamed, and help to give us a taste of luxurious growth so delightful under summer climes. Various Arabis, alpina and alhida, do well. *Cerastium tomentosum*, *Saxifraga cordifolia*, *logifolia*, *Sedum album*, *targidum*, *atropurpureum*, *Soldanella*, and the common hitting Stonecrop all make a useful show; the last, picked up in quantities on the shore, is frequently remarked on, as also are the varieties of the common Sea Pink, with their refreshing clumps of all the year round green foliage. The common Biedderwort, with its close silver growth and white flowers, also upholds the claim, often overlooked, of local wild flowers to a place beside their rarer fellows. Other alpine dwarf-growing plants might be mentioned which thrive under conditions into which many would hesitate to introduce them; but the herbaceous borders are after all the mine of wealth, since they contribute to the brightness of church, home, and sick-room, as well as make the garden gay.

In a border under a north wall the annual Hop (*Humulus japonica*), *Tropaeolum canariense*, and other Nasturtiums help the Woodbine, Ampelopsis, and Ivy to adorn what flowers

cannot be prevailed upon to cover. The common Woodruff enjoys the shade at their feet, and makes, with the perennial *Myosotis*, a close carpet background. Clumps of *Iris virginica*, *florentina*, and other commoner kinds, annual *Snailflowers* (*Stella* for choice), Lupins, the only Rose that seems to flourish (*Rosa alba*), tall White Lilies, masses of *Michaelmas Daisies*, *Pyrranthum uliginosum*, all fill in the middle distance, and if the foreground is not thick with Pansies or Violas, patches of White Harebell, and the crimson-leaved Clover, it is filled up with useful annuals, like the *Saponaria calabrica*, *Asperula*, *Nemophila*, and *Phacelia campanularia*. But of hardy annuals there is no end. A search for the less popular kinds is well rewarded. *Dalphiniums*, perennial *Sunflowers*—*Miss Mellish*, for instance—*Veronica*, *Lychita chalcidensis*, *Catherbury Bella*, and *Gypsophila*, with Foxgloves and Mulleins, all have their place. Hollyhocks are tied in against the fence or trellis shelter. *Campanula carpatica* and *pumila*, too, make lovely masses of bloom on bank or pathway border. The *Eryngium* make sturdy growth in quite exposed positions. *Dianthus deltoideus* loves a sunny and dry bank. The Spanish *Iris* contributes generously to the cut-flower basket, while nothing exceeds the brilliance of *Poppies*—*orientalis*, *nudicaulis*, and many another. It is astonishing what an effect may be obtained with masses of dwarf *Nasturtium*, and for a bedding cut plant *Antirrhinum Queen of the North* is a special favourite. Dahlias, I find, make a fair display pegged down on the beds to save them from the wind. Compensation for the failure to grow Roses is to be found in an abundance of Carnations. Soil and climate have no terrors for Ruby Castle, Duchess of Fife, the Old Glove, Mrs. Sinkins, and Her Majesty—they seem on the contrary to give an added depth of colour. I have not mentioned half the forty varieties I picked one day last summer, but enough to prove my point—a garden may, like all else, rise superior to its surroundings, and make the most cheerless prospect more kind and cheerful by furnishing a flower foreground. A spade and rake, a friendly feeling for flowers, with a natural sympathy for their needs, not to mention the possession of a few friends with old-established gardens, will suffice to turn many a wilderness into a place of flowers and happy memories. It certainly may be said of gardens—"folk never know what they can do till they try."

SEMPERFLORES.

RENOVATING CARNATION BEDS.

A CORRESPONDENT recently sought advice on this matter in the columns of this journal, and as I happen to be engaged in carrying out work of a similar description at the present time, I am assuming that a short note in addition to the Editor's advice may perhaps prove acceptable. Before proceeding further I should state that there is this difference in the two cases. "E. H." is apparently obliged to make use of the old plants again, while I am enabled to dispense with them through having a good supply of young stock on hand which was layered last autumn. These were potted up as soon as rooted, and have been wintered in a cold-frame, the sashes of which have been merely used as a protection against rain, frost, and snow, and the result is the plants are hardy, vigorous, and abundantly rooted. This method I would strongly advise "E. H." to adopt next autumn, and if he cannot afford them a cold-frame or pit, then allow the layers to remain attached to the mother plants until the spring before separating them, and then to plant them wherever he may desire. In some localities layers as soon as rooted may be taken off and planted at once in their permanent quarters with success, but such cases are not general, for what with damp and frost alternating during the winter months, the losses are often very severe, and I have before now witnessed the destruction of quite one half of the plants from those causes.

In my own case, I am removing some of the stumps from the borders, as it is, from having had constant applications of manure year after year, little better than a mass of humus, and am replacing it with parings from the edges of walks and drives which have become thoroughly rotted down. When incorporated with the remainder of the soil in the borders the result

will be an ideal compost for Carnations, and one I am looking forward to giving excellent results. With regard to planting, my plan is to set out the plants in "threes," and in triangular fashion, each group of plants standing 2 feet apart, and the same distance between the rows. If care be taken to make the groups of plants angle with those immediately in front or behind them, as the case may be, the beds or borders at once look well furnished, and the floral display is also considerably enhanced later on by the use of the additional number of plants. Seedlings, of which I like to raise a few annually, I generally plant in lines in the kitchen garden for cutting from, and should anything extra good appear among them they are propagated by layering as soon as the plants have ceased flowering. A. W.

WATER GARDENS.

For many years our ponds, streamlets, and lakes were left very much to themselves, no thought being bestowed on the plants useful for

DRY FLOWER BORDERS.

A FLOWER border, where the soil is not merely shallow, but poor, is not the place one would choose for many of our favorite garden flowers. In too great a number of instances, however, the selection of a garden is not left with the individual, as more frequently than not it is one of the things that has to be "taken to" with all its attractions or failures. Borders that are naturally dry from the position they occupy, where perhaps the subsoil is gravel, and thus moisture quickly drains away, have at times to be taken into account. When can one improve such a border, and in what manner, are questions that suggest themselves to one's mind, and perhaps at no other time of the year are they so convenient to deal with. At this time, when plant life is moving, when borders are, as a rule, practically bare, one can take in hand the re-invigorating of one's flower borders, so to speak, and make such arrangements as will tend to the prolongation of many of the blossoms that follow in later days. Let a start be made then

As within the next few weeks much planting has to be done, and seed sowing to be gone through, a list of subjects suitable for dry borders will interest some readers similarly situated in regard to their gardens. One of the earliest lessons I had to learn was this—that it was almost futile to plant to any extent hardy herbaceous things on a hot, sunny border as late as March, and expect them to do well the first season. It is a temptation that comes to many as they go into a flower-market in March and April, when Phloxes and Campanulas, Pyrarthura, Dicentra, etc., are offered for sale, to buy just a few varieties that we most want. I must plead guilty to buying so late myself, but when thus late it is well to remember that a hot, dry border, with the bright spells of April sunshine and the hotter days of May, tries very much all newly-planted stuff that has not had time to get sufficiently established. If they are to be purchased at that time of the year, give them the benefit of a north border, as undoubtedly the best period for the planting of all hardy subjects is between October and

Marillac's white hybrid Water-Lily (*Nymphaea Marilliae albida*), planted six years and never protected, showing effect in open water. From a photograph by G. A. Champin.

beautifying their surface or margin. Gradually, however, water plants are coming to the front, and an impetus has resulted from the introduction of the many charming new hybrid *Nymphaeas*, which are now largely grown in some of our best known gardens. As yet many of the best hybrids are scarce, and care will be needed and possibly protection required on the larger pieces of ornamental water where water-fowl are encouraged. In planting the choicer kinds some care is necessary when sinking them into their places. Planting is best carried out at the end of April or early in May, a simple way being to put the plants with some soil into shallow baskets, and sink them to the bottom of the lake or pond when you intend them to grow. Before the basket has decayed the plant will have anchored itself to the bottom by fresh roots. A natural mud bottom is best for Water Lilies, but they can be grown in tanks the bottoms of which are covered with a layer of heavy loamy soil about 1 foot in depth, allowing about 2 feet of water over this.

Among the hybrid kinds that have been introduced we find that the earlier raised ones are the best, the flowers being larger and the plants altogether stronger in growth.

with the soil, and, if it is to be had, procure as much new material as is possible, that from a field or pasture land in preference to any other, removing the Grass and digging out the under spit. Whether it is worth while to cart away some of the existing soil in the borders is a question for each one to decide, but, in a general way, when years have elapsed since they were made, it often occurs that the soil has sunk to such an extent as to require much filling up. Some partly-rotted dung is of much assistance where borders have a deal of sun to contend with, and if at the time of digging plenty of manure is used the advantage will be seen months later. I have had to do with borders that, under ordinary circumstances, were soon dried up, and when one could scarcely discern within a couple of hours after rain that there had been any, where plants quickly came into bloom and as quickly failed, and all because of an insufficiency of soil and a substratum of gravel. After dealing with them in the manner indicated I found that, together with a mulch of old manure in June, over which soil was sprinkled for mere tidiness, I had solved the difficulty of the early decay of many of the choicer flowers.

February, weather permitting. To return to the flowers suitable for a dry border, may I propose to those who have hitherto failed with bedding plants to try instead *Tagetes signata* *pumila* and *Moring Star Chrysanthemum*? *Jacobinas* are very showy, wonderfully profuse, and may be raised from seed in a cold frame. Where I have failed with the perennial *Larkspur* I can generally succeed with the annual forms, and these are most attractive in a border. Then one must not forget how all through a long, dry season the *Gaillardias* bloomed when other plants drooped. *Portulacas* and single *Petnias* are both pretty and bloom well grown under circumstances not adverse to many plants. The common yellow *Chrysanthemum* often to be found in the field—viz., *C. segetum grandiflorum*—is worth the attention of those who are on the look-out for a cheap annual to produce an abundance of blossom for cutting, and another blossom, of orange, and yellow, and brown, equally impervious to drought, is to be found in the *Coreopsis*, a charming hardy annual. How useful too is that old-time plant, the *Antirrhinum*. It is a capital plant for sunny spots that are somewhat dry, but blooms well notwithstanding. *Zinnias* are

long-lasting and brilliant, and a sunny border is the place of all others in the garden where they should be cultivated. For the first batch, sow in heat at the end of March, and plant out the first week in June. To ensure a continuance of blossoms throughout the summer sow some more seed in the open air towards the end of May.

W. F.

NOTES AND REPLIES.

Bulbs for border.—What sort of bulbs or plants could I put in a border, 16 feet by 2 feet, under sitting-room window? Aspect south-east; the soil is good, and has been turned over and manured with cow-manure last month. It has not been planted last year. I want it to look well from May to September.—Lao.

[You may plant now such things as Tigridias, Ixias in very charming variety, Gladiolus in many sections, Hyacinthus candicans, Anemone fulgens, A. coronaria var., Ranunculus, and all such things, with every hope of flowering. Of other plants, Carnations, single Pyrethroms, Gaillardia, Scabiosa caucasica, Helenium pumilum, Stenosie speciosa, Montbretias; and such easily-raised things from seed as Sweet Sultan, Asters, Zinnias, Stocks, Phacelia Parryi, Marguerite Carnations, Sweet Peas, Lupinus, Marigolds, Rocket Larkspur, Gypsophila elegans roses, Shirley and other Poppies.]

Plants for shady, sandy bank.—I have an ugly, bare piece of bank, not steep, under trees, but not densely shaded, almost pure sand, or, at least, sandy soil. Could you tell me what has a chance of struggling along there? I propose digging holes and putting in good soil and manure to start with. Being shade, I presume Tamisk would not do? I had an idea of coarse, common Feros in holes of leaf mould, but, fear it would be too dry. The spot is a great eyesore, so shall feel most grateful for advice.—Kest.

[There is not the least reason for this bank to be an eyesore any longer—indeed, it may prove to be a veritable home for not a few things that will not be grown in the ordinary way. It is in such places as these that Wood Anemones often grow freely, and common Snowdrops and Lencojum vernum form established clusters, and the lovely blue of Muscari conicum makes its most effective blaze of colour. Unfortunately, you cannot now so well plant such things as you may have done in October last, yet this is the time to follow, and none more capable of pleasurable results. What you may do now is to plant the common London Pride, dibbling single crowns over the whole area at 6 inches apart—just as a carpet for the season. Grhy making the holes you speak of, such plants as Megasea cordifolia purpurea, Petriwinkle, Euphorbia Lathyris, Linum perenne, Arabia, Aubrietia, Coronilla varia, and Alyssum saxatile may be dealt with at once, planting rather small pieces over a good-sized area. With such plants as these forming a permanent covering the hole may be dibbled in in due season, and quite a variety of season of flower result.]

Flowers for small garden.—As I should like to have a good and continuous supply of flowers in my small garden during the coming summer and autumn, I should be much obliged if you will tell me—1. The names of a few hardy annuals, and when to sow them? 2. The names of a few hardy perennials, and when to plant them? Both annuals and perennials required to be effective, fragrant, and useful for cutting.—M. F.

[The following are good of the first-named, and seeds may be sown at once: Nemophila insignis, Dianthus Heddewegii, Mignonette Golden Queen and Salmon Queen, Nusturtinum Tom Thumb, Helianthus Stella (3 feet), H. oenomerifolius (3 feet), Calliopsis, Gaillardia picta (mixed), Gypsophila elegans rosea, Marguerite Carnations, Chrysanthemum tricolor, Sweet Sultan, Coroflower, Helichrysum, Linum grandiflorum rubrum, Shirley and other Poppies, Sweet Peas. Of the perennials you may plant at once: Oeum coccineum pl., Candytuft, Doronicum in variety, Columbieus (hybrid vars.), Gaillardias, Hemerocallis flava, H. Thunbergii, Rudbeckia Newmanii, Ater Amellus, A. levisgatus, A. acris, Monstretias, Crown Anemone, single Pyrethroms, Iris germanica, Polemonium Richardsonii, Achillea mougalica, Helenium pumilum, H. autumnale, Heuchera sanguinea, Galega officinalis, and G. o. alba.]

Propagating Violets.—"C." in a recent issue, advocates quite a new departure as to increasing the stock of these valuable winter and early spring flowers, a method, I fear, not likely to be followed by many who grow their plants during summer expressly for producing flowers from September to the month of May. It may be all right for the trade, whose sole aim is to propagate rooted plants for sale; but to the

gardener who grows for a constant supply of flowers only the matter has quite a different bearing, for to encourage the production of runners from each plant during the month of August as advised (or any other month while in the open, come to that), is robbing the crowns of that energy for the production of flowers which gardeners endeavor to build up from the time the young plants are put out in early April until lifted in the month of October. Surely "C." does not wish to imply that plants treated as he advocates froish such blooms in quality or quantity as do the plants that have every runner persistently pinched off throughout the summer, as soon as the same can be laid hold of by the finger and thumb! As planting time will soon be with us I purpose to give my method of treatment in a future issue of your valuable paper, and, in the meantime, perhaps "C." would enlighten your readers as to whether his plants that have applied runners for the following year bloom as freely during winter as do those cultivated in the way I have named above. To follow "C.'s" advice, it would be far best to scorfiss, say, a hundred plants solely for the production of runners, and probably this is what he means.—J. M. B.

Violet culture.—Would you give me instructions for the successful culture of Violets, in open and in frames? The time to take young suckers? When to plant out? Whether old plants should be kept for more than one year—if for second year whether they should be thinned out? When to manure, and what manure is best?—G. J. Nov.

[The season for planting out the runners for the next season's use is in April. Usually then there are suckers which are very helpful, and the runners then are, or should be, provided with new roots preparatory to planting. Violets are best replanted every year, whether these be for outdoor beds or in frames. The situation of the bed may be open or partially shaded by trees, according to the nature of the soil. In light land, which invariably suffers more or less in dry weather, a little shade is beneficial. On more holding soils Violets are just as well, if not better, planted in the open. This applies to double or single Violets intended for frames or for outdoor culture only. Ground for Violets must be of good quality, well prepared by trenching or deep digging, and should also receive a fairly liberal addition of decayed manure and, if possible, some leaf mould. Stable-manure, or that which has been employed for Mushroom-beds, is the best for heavy soil—decayed cow-manure suits light land. It is, however, best to manure and dig up the beds in winter so that frost pulverizes it prior to the planting of Violets. Similar treatment is required for the double us for single varieties, except that the latter need more space because of their coarser growth. Single varieties of the modern kinds, such as Princess of Wales, flower freely on the runners which issue from the parent plant, and for this reason can be left. The double varieties require the runners removed frequently in summer, so as to concentrate their strength on the crown which gives the finest blooms. In frames the plants should be so arranged that their leaves come within a few inches of the glass lights, over the whole extent of the bed. Unless they are kept well up to the light they sometimes give a deal of trouble from damping of the leaves. Ventilation is an important item in Violet culture. This should be given freely on every favourable occasion, and the lights are best removed daily in mild weather. Good lumpy soil should, if possible, be provided for planting in pits, adding a little wood-ashes and leaf-mould but no manure. A little fresh soil is given as a top-dressing early in March the runners become stronger and better rooted for planting out-of-doors early in April. Besides being kept moist at the roots by occasional watering, their growth is much benefited by an overhead sprinkling in the evening during the summer when the surrounding soil is hot and dry. While this promotes a healthy growth it tends also to keep down red-spider.]

Plants for pergola.—I am making a pergola across path running from north to south. The pergola is to be 73 feet long and 11 feet wide, and will have thirteen upright poles a side at 6 feet apart, 3 feet high, and about 5 inches in diameter each pole. I want to plant it with different Rambler Roses and any other quick-growing sorts you would kindly suggest. Should I only plant one climber to each upright, or, as they are a good size in diameter, could I plant two—one on the outside, and one on the inside towards path? I want to plant the different Ramblers alternately with other good, hardy climbing

Roses so as to keep up a longer period of blooming. I should be most obliged if you would give me the names of some Roses other than the Ramblers, of the same type and class as the Gloire de Dijon, Blairi No. 2, etc. I have Bardou Job a quite hardy and quick climber? As my uprights are 6 feet apart I should like to plant between each (at 3 feet) either a Climatis or some other flowering climber, but do not quite see how I am to train them up unless I make a complete lattice-work of wood between the uprights, which I did not want to do. I should be most grateful for any suggestions on this point. I want to plant a row of the China Monthly Roses all along the bed between the uprights to make in time a close, low hedge. If you think this suitable, kindly tell me how near I can plant them, and if it is best at once to train them as a hedge on wire, or can they be left their first season as bushes.—T. M. D. H.

[It will be better, we think, to plant each side of the uprights, as by this means seed employing various kinds only will you be enabled to secure an extended flowering season. Your difficulty of planting something between the uprights, while not completely latticing in the sides, may be overcome by your employing Larch poles that have not been too closely spurred back, or something akin to this in point of ruggedness, etc. But having the uprights so near as 6 feet apart, we doubt the advisability of planting between such spaces, unless it be for temporary effect. When the overhead climbers become established there should be enough of drapery to hang down the sides if the plants are carefully trained. Planting a pergola with the rightful subjects is a question of time and not less of preparation. In the latter connection, for example, it is a good plan to plant a few tall Briers for stocks, so that these may be worked at 8 feet high. This would more quickly give you the top covering than by waiting for all the plants to climb simultaneously. You will find in the following list some of the best of the Rambler and free-growing sorts: Aglaia (Yellow Rambler), Euphroayne (Pink Rambler), Thalia (White Rambler), Alice Gray, White Macartney or alba simplex, Bardou Job, Blairi No. 2, Dundee Rambler, Félicité-Perpetue, Queen of the Belgians (creamy-white), The Garland (mauve and pink), Vivid (bright scarlet), Mma Alf. Carriere (white and yellow), Rampant (pale white), Paul's Carmine Pillar, Polyantha grandiflora, Rosa macrantha, and R. setigera, the last a large flowered and late-blooming species. This is the "Prairie Rose." The yellow and Austrian Copper Briers would be very beautiful on the uprights. Other excellent climbers are: Alioter Stella Grey, Almé Vibert, Abbe Thomaseon (very fine), L'Idéal, Mma. Barard (a perfectly hardy and free type of the Gloire de Dijon stamp), Acidalia (white), Fulgens, Mma Plantier (pure white), and the climbing Souv. de la Malmison, form the cream of the most vigorous climbers. Not a few of the latter are late flowering. The China Monthly Roses intended to form a hedge would be best allowed as bush plants for perhaps the two first seasons, and, assuming quite a low hedge is required of these, you will do well to obtain only the smaller plants for the original planting. By foregoing any special preparation in the planting a smaller growth calculated to make the best and densest hedge will be formed of such things.]

Sweet Peas—raising plants under glass (Uncertain).—We assume, from the brief manner in which you have expressed yourself, that you desire to have a continuous display of these beautiful annual blossoms from the early summer onwards. You must observe the greatest care with the first batch of plants, or they will quickly become drawn and weakly. As you are keeping the glass structure comfortably warm, there is a danger that with more genial weather the increased heat, owing to the sun's influence, may be far too much. See that the earliest batch of plants is placed on shelves near to the glass roof of your greenhouse, and also ventilate freely. Watering must be regularly attended to, as the soil in the 5-inch pots quickly dries up. It is a mistake to keep the soil in the pots in which the Sweet Peas are growing too moist at this early period, therefore, when going over the plants each morning, water only those which appear to be rather drier than is desirable, giving such plants a thorough soaking. As a rule, this will suffice for some days. In the meantime the second batch of plants will be pushing through the soil, and that they may not become drawn see that the pots are placed on shelves near the glass roof, as was observed with the earlier lot of plants.

Never allow the growths to become longer than an inch before placing them on the shelves, as previously described. Sturdiness in the early stages of the seedling plants is an essential to success. Cold-frames have their advantages at this season, and are valuable as the season advances. The earliest batch of plants should, therefore, be placed in the cold-frame as soon as they have become fairly sturdy, and somewhat hardened off in consequence. Give each pot ample room. The young plants will need the support of spriggy little stakes when their height exceeds some 6 inches or more. When arranging the plants see that the spriggy stakes in one pot do not touch the stakes of those in the adjoining ones, otherwise the shoots will quickly become interlaced. Air may be given freely at all times, except in frosty weather and during the prevalence of cutting easterly and north-

anes, they continue in flower over a long season. The double flowers, we think, lack the elegance of the single blooms, but they last well when out, and also make a bright show in the open. The so-called St. Brigid Anemones, like those of Caen and Nice, are simply selections from the Poppy Anemone, depending for their value on care in selection, and also on good culture in the warm limestone-soil the plants so well enjoy. —Ed.]

COTTAGERS' GARDENS.

A VISIT I paid some time ago to a number of gardens managed by cottagers that were entered for competition "for the best kept and most tastefully arranged garden" in connection with the show held in the village, corroborated the opinion I had previously formed, that some flowering plants, common enough in most

subjects in them, but they were of a high standard, and, like those depicted in the illustration, were planted so as to bring about a most excellent display. In fact, the best gardens were those where the fewest sorts were grown, strange as it may seem. The main idea with the grower evidently was to cultivate well the few in preference to the many. In the garden, for example, that was subsequently awarded first prize particular attention had been paid to the growing of Campanulas, Pyrethrums, Lilies, and Fuchsias; in another, Begonias, Zonals, Stocks, and Asters rivetted one's attention, and in a third Zinnias, Verbenas, Gladioli, Marigolds, and Carnations had been well grown. The large number of flowers of a particular variety and often of one colour seemed to bring about a very nice effect; especially was this so with Asters, Stocks, and Zinnias. Horticultural societies do not, as a general rule, set aside much money for prizes for the best cultivated gardens, their object being rather to encourage the exhibiting of flowers, fruit, and vegetables to be brought within the show tent and attract the people, and so augment the funds of the society, but where arrangements can be made to offer facilities to cottagers in the manner described, it not infrequently follows that keen competition is evinced by them in other classes of the show—at least, my observation has led me to such a conclusion. Some plants seem to be better grown by cottagers than do others, and besides those already referred to one may mention Delphiniums and Phloxes, some of the finest spikes at many of our exhibitions coming from cottage gardens. Pentstemons, annual Larkspurs, Canterbury Bells, and Gaillardias are flowers in which cottagers take the greatest interest. Fancies, too, are special favourites with many, and not a few first prizes are awarded in the cottagers' classes. One cannot be surprised at this, considering what time they devote to their gardens, often, in the summer, finding pleasure in them in the early morning before the day's work commences, and then again at night till darkness sets in. In this self-same hamlet to which reference has been made other cottagers' gardens, superior to those I had before seen, attracted my attention. There were several semi-detached houses, along the front of which a verandah had been erected, covered then with Roses, Clematis, Honeyuckles, Jasmines, etc. The houses were all tenanted by old people, with some of whom I had a chat, and who told me that the houses had been built years before as "almshouses." It must have been a kindly thought which prompted the donor to establish such residences for the old folk in the first place, for they bore no sign of the "poor-house," save that under one of the porches over the lintel of the door, partly covered with creepers, I read the inscription:—

"At evening time it shall be light."

But for this no one would have imagined them to be other than well-built cottages for private individuals, and the small lawns at the front of the houses, containing gaily filled beds, and about which there were seats placed, all testified for a consideration on behalf of the inmates. Borders too on either side of the paths exhibited much beauty—Dielytras and Rock-roses, Foxgloves and Pyrethrums were there, and as one went away one could not help contrasting the lot of these old people whose closing years had been lightened with that of others who had to toil hard to the end of the chapter, under conditions so adverse and disheartening, and just as the day was sinking one could not help recalling other lines:—

"When the brooding twilight
Unfolds her starry wings;
And worn hearts beam with tenderness
The peace that evetide brings."

LEAHURST.

EAST LOTHIAN STOCKS.

THESE beautiful and fragrant flowers are indispensable in every garden, and invaluable for cutting. Moreover, if the plants are mulched and assisted with liquid-manure, they will continue flowering for several months. Some raise a batch of plants in autumn and keep them in small pots all winter, shifting them into larger ones in January, and treated thus they make grand specimens for the embellishment of the conservatory or for cutting from in April and

A Somersetshire cottage garden. From a photograph sent by Mr. J. Walters, Yeovil.

easterly winds. Plants treated in this way may be planted out in mid-April or even earlier with little risk of failure. The second batch and others succeeding it should be treated in like manner, and if your cold-frame accommodation is somewhat limited, each batch should succeed in its occupation as they are in turn planted.

Poppy Anemones from Ireland.—We are sending you a few of our strain of Poppy Anemones. We can now gather flowers in over thirty distinct colours, and have close upon four acres of this glorious plant, which blooms from nine to ten months out of the twelve, and is, without doubt, the best winter and spring-blooming hardy plant in cultivation.—REAMS, NORRIS & Co., Alderborough Nursery, Geashill, King's Co., Ireland.

[A very beautiful gathering, the flowers varied in colour, and of good substance. There is now a wonderful range of colour in the various Poppy Anemones, and, what is of even more import-

gardens, were specialised, as it were, and cultivated by them with such enthusiasm and thoroughness as to bring about a really fine display—indeed, to such an extent as to draw people to the gate for a glimpse of borders that had become the envy of the villagers, and, as some of them justly remarked, "were the finest they had ever seen." Where these cottages are situated matters little now; suffice it to say that during a holiday ramble once I found myself one evening in one of the prettiest villages it has been my fortune to set foot, where much interest is taken by the landlord proprietor in the gardens on his estate. In most of the places into which I sauntered one noticed that great pride was taken in the flower borders, and one of the things which surprised me most of all was this, that although many of the borders were undoubtedly showy, it was not due to the great variety of plants one saw, for in three or four of the gardens, which were exceptionally bright, and to a casual observer were among the prize-winners, there were very few

May. The seed may be sown at any time in February in gentle heat. Some advise sowing in January, but as there is then little sun the plants are generally weak. The less artificial heat employed the finer will the plants be. Sow in fine loamy soil, with a small quantity of old Mushroom-bed manure added, also a little coarse sand or grit to keep it open. Sow thinly, as if the seedlings are crowded the surplus ones cannot be thinned out without the rest being loosened, which is an evil. Keep the soil moist, and as soon as the plants are up place them close to the roof glass, and if possible near the ventilators, as they require plenty of air and light. Syringe them lightly occasionally, and as soon as they can be beniled prick them out. A frame in which early Radishes have been grown suits them best, as they are near the glass and the gentle bottom-heat induces a sturdy growth. Moreover, they entail less labour in watering than when in boxes or pans. A little of an approved fertiliser should be mixed with the soil in the frame, which should be made firm. The soil in the boxes should be of a loamy nature, and should contain a fifth part well-decomposed manure and sand. Stocks enjoy a good larler, and the soil should be rich from the first. Keep them in a little heat till established, then remove them to a sunny greenhouse or pit, and a fortnight later to a frame facing south to harden off, finally planting them out in April. The bed or border intended for them must be well enriched with good manure; cow-manure is best, and if Stocks were grown in them the previous season a little of the soil should be removed and replaced with fresh from the compost yard. If a small percentage of roadside parings, chopped fine, are added, so much the better. Plant firmly, allowing a distance of 1 foot to 15 inches between each plant, and mulch with light manure or leaf-mould. Mulching is important, as Stocks like a moist root run. When growing freely assist them frequently with weak liquid-manure, or mix a small quantity of artificial with the mulching occasionally, and water it in. Pick off all exhausted flowers, as if left on the plants they soon impoverish them. Amateurs who do not possess a heated structure may grow excellent Stocks by sowing the seed in a frame in March, and treating the plants as above described. Be sure and obtain the seed from a reliable firm. SUFFOLK.

ALSTROEMERIAS.

I READ with interest in a recent issue "S. W. F." experiences of *Alstroemeria chilensis*, and would like to give you my own. My late garden was light loam. *Alstroemeria chilensis* grown from seed gave no trouble and produced fine blooms. On coming here, in March, 1900, I sowed three new beds. The soil is heavy. Two beds were dug in the ordinary way, with a little manure added; the first year a few wretched plants came up very patchy, and the second year, though they were given a good top-dressing, the result was so poor that I have had them dug up. The third bed was sown on deeply-trenched clay, with plenty of good farm-yard manure at the bottom, and with leaf-mould and manure top spit. From September to November the heads were in full bloom; seeds were cut off as soon as formed, and in the summer of 1901 the results were as good as I could wish. "S. W. F." says that some people have difficulty in growing this lovely perennial. I have given seeds to friends, some of whom say they get one or two miserable plants, while others have lovely beds. I find the colour can be much improved by judiciously selecting the seeds. What can be more beautiful and more lasting than a vase of these Lilies, cut with long stems and arranged with the larger and branching varieties of the wild, roadside Grasses?

Lincoln.

G. M. S.

Photographs of Gardens, Plants, or Trees.—We offer each week a copy of the latest edition of the "English Flower Garden" for the best photograph of a garden or any of its contents indoors or outdoors, sent to us in any one week. Second prize Half a Guinea.

The Prize Winners this week are: 1, Mr. W. A. Leslie, Corniston Towers, Biggar, N.B., for Rhododendron Lady Alice Fitzwilliam; 2, Mr. W. Burrell, Stanley House, Milgraves Road, Sutton, Surrey, for Summer house.

ROOM AND WINDOW.

GREENHOUSE CULTURE OF POLYANTHUS NARCISSUS.

THE bulbs are of first-rate quality, and from a good man. The flowers are produced, but the heads are poor and stalks short. When should they be potted, and when taken into the house? Night temperature of house about 45 degs. lowest.—See below.

[All the varieties of *Narcissus* *Tazetta*, bunch, or *Polyanthus* *Narcissus* produce bulbs of large size, or, rather, of exceptional size. To be successful in flowering these kinds several items over which those flowering them have little control are essential. Firstly, the bulbs must be of first quality according to their kind, and,

moisture, both being kept up till the flowers begin to open. A large bulb of one of these will send out a flower-stem 2 feet long and a dozen flowers at its crown. By your description of short stalks and poor heads, we imagine you have potted them far too late, and in a poor condition they are poor indeed.]

CHRYSANTHEMUMS.

SIX EARLY-FLOWERING POMPONS FOR BORDER CULTURE.

(REPLY TO "J. H.")

We congratulate you on winning second prize

Polyanthus *Narcissus* in pot. From a photograph by G. A. Champion.

duly harvested, should be potted up in a good rich soil in September, if possible, but certainly in the following month. Only in this way can the root-fibres perform their functions. Bulbs potted late, particularly in December and later, cannot flower well, albeit the bulbs may be fully as large as earlier-treated roots. Potted at the time stated, given a soaking of water, and plunged 6 inches deep in ashes, roots will be made apace, and upon these the good flowering chiefly depends. Such early-potted bulbs may be taken into the greenhouse in mid-December, and, watered abundantly, progress will be brisk as the days lengthen. A temperature of 45 degs. at the start, to be raised in two sections of 5 degs. in a month, will suffice. Great quantities of water are necessary, and almost of equal weight is atmospheric

last season for beautifying your cottage garden with early-flowering *Chrysanthemums*. You limit the selection of sorts, as you say the gardens have to be judged somewhat early in September. Now, there are several very pretty sorts of ideal habit which we can recommend, but had the period of flowering been extended into the early days of October the selection of sorts would have been a much better one.

MR. ED. LEFORT.—One of the finest flowering *Pompons*, bearing large, well-shaped blossoms of an old gold colour, shaded with red, and prettily frimbriated. The plant attains a height of about 2 feet, and comes into flower from the beginning to the middle of September.

MR. SELLY.—A distinct and pleasing *Pompon* of pretty peach-pink colour. The blossoms are of medium size, freely produced, and each

flower may be gathered on a useful length of footstalk. Height about 18 inches, habit bushy. This variety is in flower from late August and also during the whole of September.

Mrs. E. STACEY.—This is a charming sport from Mr. Selby, and partakes of all the excellent characteristics of the parent plant. In this case the colour is a pleasing spricot.

ANASTASIA.—This is an old sort, but it has many good points. The plant does not exceed 20 inches in height, is wonderfully branching and sturdy in its style of growth, and bears a profuse display of dainty rose-purple blossoms tipped with gold. The period of flowering commences in late August and is continued throughout September.

LITTLE BOB.—In this the colour is a rich chestnut, which passes to a deller shade with age. The blossoms are somewhat small, but they are so freely produced that the effect is very striking. Height about 2 feet; blossoms continuously from mid-August till severe frosts ensue.

Mrs. JOLLIVANT.—A very free-flowering plant with a bushy habit of growth. The blossoms are white shaded with pink. Height about 18 inches. It is in flower during September.

TREES AND SHRUBS.

THE MYRTLE.

Though the true home of the Myrtle is in the sunny south, such a fragrant shrub is cherished by all who love their gardens. We can grow with care luxuriant hedges of every sort of the common Myrtle against a sunny wall, and if a severe winter takes them from us we must replace them. In Cornwall and Devon the Myrtle is seen as a bush in company with the Fuchsia in a tree-like way, but inland we must be content with it as a wall covering, and a most beautiful covering it makes. The common broad-leaved kind as seen in most old gardens has been with us since the culture of foreign shrubs began in England, and therefore a peculiar interest attaches to it. But there are many other kinds which one sees commonly grown in Italy and the south that excel the typical kind in beauty of flower and foliage while retaining the belmy fragrance. The dwarf sorts are the Roman, Box-leaved,

A spray of Myrtle.

Nutmeg, Portuguese, Italian, and the Dutch, all different and having characters that recommend them, but, unfortunately, they are difficult to obtain. One of the best and one that is procurable in nurseries is the Rosemary-leaved Myrtle (*M. communis macronata*), also called *minima* or *angustifolia*. It has much smaller leaves than the common kind and produces a sheet of white feathery bloom against a warm wall. Besides these more or less botanically distinct varieties there are several with variegated foliage, such as the gold-striped, silver-striped of the various forms mentioned above, but they are not so desirable as the simple green-leaved varieties, and are mostly grown in pots for cutting from. In any but the mildest localities or near the sea the place for Myrtles is a wall where they can get plenty of sun, and if there is an overhanging ledge, such as a window-sill, so much the better.

"Farm and Home Year Book."—We are glad to be able to state that the "Farm and Home Year Book" seems to have met with our readers. Its reception by the Press generally has been most cordial, and the demand for it has been so great that a third edition has been issued. Our readers should have no difficulty in obtaining it from any local bookseller or newsagent, who will order it if it is not in stock; or they may get it direct from the Publisher, 37, Southampton-street, Strand, by post, 6s. 3d.

FRUIT.

DISBUDDING PEACHES.

Will you kindly explain what disbudding Peaches is and how it is done? I have just planted five trees in the Peach-house, and want to know how to proceed so as to have good trees and crops? Is the object of pruning Peach-trees to have fruit on the side growths? I have a lot of bloom showing on the side growths of an Apricot-tree. Is there any good work on the cultivation of Peach-trees?—W. F.

[It is difficult in the space of a brief reply to give sufficient detail to clearly describe the work of disbudding in Peaches. There is a deal of necessary study and application to carry on the growth of trained Peach-trees successfully. They are so profuse of growth that disbudding must be continued over a lengthened period. It is a bad plan to remove all superfluous shoots in one day. It is better to extend this over a week or even two, to avoid the check to the future growth. Nor must fruit be considered the first year of planting. It is better, in fact, to remove any flowers there may be in a bad state now. In the course of disbudding Peaches and Nectarines always choose a well-placed shoot as near the base as possible of every existing principal one, allowing as a leader the bud growth at the extremity of the same. If the matured branch should be of a fairly good length, then allow an additional shoot between these two. In the case of a young tree not yet fully furnished this course would be easy. The object of the choice of the basal growth is to provide for the fruiting growth of the following year. Often the growth allowed from the extremity is pruned back, though not in every case, to the fruiting shoot behind it. Much of this depends on the tree itself and the fulness of its furnishing. Crowding is confusing, causing unnecessary labour, and is not good for the trees, thus disbudding should be carried out so that this after trouble is avoided. Always choose permanent shoots on the upper, not the under, sides of existing fruiting wood. These that occur on the under sides are the first that can be removed. In many instances there will be at least ten shoots where two only are required, thus it is advisable to retain those best placed for the formation of the future tree. Manipulation of the green shoots of Peach-trees becomes in itself almost a fine art, which cannot possibly be dealt with in a fearless manner by the amateur grower. A little professional assistance is of great value in giving a proper insight into the initial courses of tree manipulation. Except in the case of a very strong shoot, no stepping of Peach growths is necessary, and the lateral branches formed this year are those which produce fruit next season. Apricots differ in their habit from Peaches and Nectarines in that once the trees are well shaped the future crops are produced on short spurs, formed by pruning in summer and winter. Peaches fruit on spurs, but it is not a natural course of production. Tying or nailing, whichever course is taken, of the growing shoots must be undertaken periodically, so that they are early trained into their proper shape, and make sure they are kept free or in front of the wires, and are not too tightly bound. Always allow room for the expansion of the shoots of any tree, so that their progress is not hindered throughout the growing season.]

NOTES AND REPLIES.

Gordon Apples.—I have just been reading the interesting articles in last week's issue on Gordon Pears and Cox's Orange, and should be much obliged if you would give me some information. I have two south walls. Would it be profitable to plant cordons, with a view to selling the fruit? Would a Pear, such as Doyenne du Comice, or Apple Cox's Orange, be likely to pay best? If I purchase maiden trees is it advisable to cut them down to within a few inches of the union if I only want single cordons?—P. W.

[Before we can advise you as to planting cordon fruit trees against your south walls, we should like to learn something as to their height. Except to grow on maidens into cordon form for a year or two, 4-foot walls are too low, 5 feet are better, and still better are walls reaching from 6 feet to 9 feet in height. In training cordons, let the wall be low or high; additional length for the trees is obtained if trained slant-

ingly, although at but a moderate angle. That also seems to conduce to fruitfulness. You can plant either Peas or Apples 14 inches to 15 inches apart. If you get maidens and plant them, shorten back the shoots one half their length to cause the back buds to break. Also carry on the top shoot as a new leader. In the summer the side shoots must be cut back to about four leaf-buds at the end of July, the spurs being still further cut in to two buds in the winter. Continue that treatment each season. Doyenné du Comice Pear is of superb quality, but is not a great bearer. Probably Maria Louise, Louise Bonne, or Pitmaison Duchess would pay better. You should have both Cox's Orange Apple and a Pear.]

Twelve dessert Apples.—Would you kindly give me in your paper a list, as a reader of GARDENING, of about a dozen good eating Apples, suitable for planting as espalier trees—omit Blenheim Oranges and Ribston Pippin? Is the present season too late to plant?—O. J. Nox.

[The planting season may be said to be almost brought to a close at the end of February, but if you can get your trees from a local nursery, and their transfer can be effected without the trees being long exposed, there is no reason why you should not succeed. You can do much to help them to become established by a mulching of short manure and applying water copiously in dry weather. Partial pruning, too, will tend somewhat to relieve the strain on the roots. The season, retarded by the recent spell of severe frost, will be all in favour of late planting, and will, in fact, be resorted to to a good extent by nurserymen simply because the ground has been held frost-bound for so long, causing delay in the execution of orders. The following will be a good selection, as affording a supply from August until April or later: Beauty of Bath, Red Astrachan, Worcester Pearmain, Banmann's Red Reinette, King of Pippins, Cox's Orange Pippin, Claygate Pearmain, Scarlet Nonpareil, Court Pendu Plat, Mannington's Pearmain, Strmer Pippin, and Allington Pippin. A good, though not a showy, Apple for midwinter and until March is advanced is the old Cackle Pippin, and a useful and very bright little Apple for the autumn is the Duchess of Gloster. Gravenstein, too, is a highly aromatic, finely coloured, and good Apple that may be included in a select list. This is an Apple that birds and wasps are very partial to in autumn—a good criterion of quality.]

GARDEN WORK.

Conservatory.—The New Holland plants are lovely now. Acacias, Eutexias, Ericotomons, Bononias, Pimeleas, Chorozemas, etc., when well done are especially interesting. But most of these are relegated now to Kew and other botanic gardens, and in this respect our national gardens are doing good work. The demand for long-stemmed flowers for cutting has had more to do with the neglect of these beautiful, handsome plants than anything else. I was looking round a large garden some time ago that was at one time celebrated for its collection of plants, and which is now almost entirely given up to growing flowers for cutting and plants for table decoration and general furnishing. Palms are graceful, and the number raised in this country and imported from the Continent is astonishing, especially in the case of Kentias, which I consider the most useful family. It is astonishing in these days of keen competition how well the Kentias keep up their value. This is due to the very large demand. In every village and in almost every cottage residence Palms are now seen. This is the season for repotting any Palms which may require more pot room. The continental growers use a lighter compost than we use for Palms, with the view probably of hurrying on the growth. They also grow their plants in strong heat, and unless well hardened they are not so lasting in the drier atmosphere of the dwelling house as the cooler grown plants. Palms are easily raised from seeds, but they move very slowly in a low temperature, and the specialist with convenience for their rapid growth in the shape of heat and moisture can do the work better and cheaper. Palms will not stand strong sunshine, especially under glass, and if a leaf gets scorched the plant is ruined for a considerable time. If the plants have to be grown in pots of a limited size, good loam, rather heavy, should form the staple. The drainage should be small,

and when the roots have pretty well filled the pots liquid-manure should be used. Very weak and clear soot-water will be useful in giving the plants a dark green colour. Only soft water should be used for syringing, as lime in the water will spoil the appearance of the foliage. The regulation of the growth of the climbers must receive prompt attention now, and when the climbing growth is judiciously spread under the roof a grateful shade will be afforded when the sun gains power by-and-by. Only moderate fires will be required now.

Stove.—With increasing daylight more moisture will be required both at the roots and also in the atmosphere, but newly potted plants must be carefully treated till their roots become active. Many a valuable plant has been ruined by over-watering immediately after repotting. For a time the syringe will pretty well suffice. Such bulbous plants as Gloxinias, Achimenes, Oenotheras, etc., will be waking up now, and should be brought up to the light and encouraged to grow. Repot Caladiums when they start into growth. If more stock is required the corms can be divided. Repot Allamandas and other climbing plants which are grown in pots. An effort should be made to clean Stephanotis floribunda from mealy-bug before the plants come into flower. The Torenia are pretty basket plants and may be raised from seeds sown in a brisk heat. Rivinia humilis is a pretty berry-bearing plant. Nice little plants may be had in 5 inch pots. Seeds grow freely. With us the seeds drop about and grow freely. A good stock of winter-flowering Begonias should be rooted now. The variegated-leaved Begonias seem to be coming up again. Most of the Begonias may be propagated from leaves. Night temperature now 60 degs. to 65 degs. Ventilates freely on warm, mild days. Plants in bloom will soon require a thin shade when the sun is bright in the middle of the day, but it is as well to do without shade till plants appear distressed.

Pines.—Successions will require shifting into larger pots this month, and the bottom-hat beds trodded over and renewed where necessary, but with hot-water pipes beneath the beds the question of renewing pinning materials is not so important, but the stuff should not be left in till reduced to mould. When I grew Pines largely I used loaves for plunging, and changed them annually. Pines do very well planted out, but after some progress has been made in pots, and after the first frosts have been formed, two of the best suckers are left for the next crop. We have often left three suckers on Queens, and had three good fruits to each stool. I cannot quite see the force of giving up Pines growing in private gardens; all other fruits have come down in price as much, in proportion, as Pines. Of course they want a rather high temperature, but pot-Vines, French Beans, and other things, have been grown with them to help to pay for fuel.

Melons.—This is a good time to plant in hotbeds when the necessary heat can be commanded, but in these days of cheap glass Melons for the early crops, at any rate, are worth a warm, rather low-span roofed house, not of too steep a pitch. In a house with a steep-pitched roof it is very difficult to keep down red-spider. Put out strong plants in good sound loam made pretty firm. Have a comfortable bottom heat and a night temperature of 65 degs. Give enough ventilation to have firm, hard foliage, and do not shade. Let the plants get within 15 inches of the ridge before stopping, and pinch the side-shoots one or two leaves beyond the fruit, as far as possible together, on each plant. The number of fruits on each plant must be determined by the variety and strength of plant, but from four to six fruits to a plant are a reasonable crop where the fruit must be grown fit for table.

Window gardening.—There is plenty of bulbs of all kinds now. If potted early, Hyacinths, Freesias, Narcissus of all kinds, will be in flower now under quite cool treatment. Cinerarias, Primulas, double and single, Dentizas, and Lily of the Valley, are plentiful now. Cyclamen also are charming. Double Primulas and Cyclamen will not require so much water as the other things. Cutting of the hanging Campanula will strike now. The growth of Mosaic is moving now, and the pots should be overhauled.

Outdoor garden.—Hardy annuals may be sown outside at any time during March or April when the weather is suitable. The earlier they are sown under favourable conditions the sooner the plants will flower. Certain things, such as Sweet Peas, will be sown several times for successive blooming. Most people either sow in autumn or raise a few plants in pots under glass for the earliest lot; then a second sowing can be made in March and again in April. Mignonette should be sown freely. The Night-scented Stock should be sown near the house for its fragrance in the evening. Cornflower is useful for cutting. These are usually sown in autumn and again in spring. They will transplant well, and must not be crowded. We generally plant a foot apart to obtain fine flowers. Other useful cutting flowers are the various kinds of annuals: Chrysanthemums, Coreopsis, Gaillardia Lorenziana, Indian Pink, Sweet Sultan, branching Larkspur. The Lepotosiphous are pretty edging plants, and may be had in separate colours of white, yellow, and red. Phacelia campanularia is a pretty dwarf flowering plant. Nemophilas, Nasturtiums, both dwarf and climbing, are useful and cheap. The Convolvulus family is also bright and effective. The tall kinds of Lupinus are useful to sow round the shrubbery in new places. Sunflowers also, especially the newer forms, can generally be utilised in new places. Carnations may be planted as soon as the beds are ready. A sprinkling of soot will be useful if there are wire-worms in the garden. Scatter it over the surface and fork it in. Keep off the ground when the surface is damp. Trifolium Pinnatis go in well now.

Fruit garden.—As soon as the sap flows freely grafting may be done. There are far too many kinds of Apples, and it would be a great advantage if the inferior kinds were regrafted with better sorts; especially is this desirable where it is intended to market any of the fruit. Another important matter is the storage of late-keeping kinds. What is wanted is a cool structure that is absolutely frost proof without using artificial heat, and this can best be obtained by building hollow walls, the roof being thatched and lined inside with matchboarding. Ventilators or windows must, of course, be protected with shutters. A structure of this kind need not be very expensive, and would pay for construction if fruit is grown on a sufficiently large scale. For a good many years we have secured a crop of Peaches and Apricots by protecting with fishing net alone, and there have generally been trees on the walls which have no protection at all beyond a rather wide coping, and there have been seasons when the crops have been so good on the unprotected trees that one has been tempted to say that in some sheltered spots no protection was necessary. Any person having nets at his disposal and who does not use them is running a risk which no sensible man would care to do, and so the coverings are brought out when the blossoms show colour.

Vegetable garden.—Cauliflowers may be planted under handglasses or in trenches in warm situations. In large gardens there are often positions in front of forcing-houses where the warmth from the house is reflected on the border, and a higher temperature secured. Here early Peas, Cauliflowers, Horn Carrots, Lettuces, and other things, are brought on long before they can be obtained elsewhere. We always sow the Autumn Giant Cauliflower now under glass in heat, and harden off and plant out during April and May, in various aspects, to form a succession during summer and the early autumn. Another sowing is made outside in April for late cutting. In the hot weather, when the early kinds of Cauliflowers are open and useless, the Autumn Giant from the early-reised plants is clean and white. It is quite true the Cauliflower often comes too large for a fastidious taste on rich land, but we get over that difficulty by planting closer in the rows, leaving the same distance between the rows, so that the air can circulate freely between the plants. To do the best with Brussels Sprouts and Leeks the seeds must be sown early. I have often wondered, considering what a wholesome vegetable the Leek is, that it is not better grown, so as to have it of large size. The same remark applies to Celery, especially the Turnip-rooted Celery, which is so good for stewing. More should be done with

FRUIT.

GRAFTING WITH RUBBER STRIP.

Now that the time for grafting is coming on, I think a few notes on the use of rubber strip for grafting might be useful. The material that I use is the pure rubber strip which is used for insulating joints on electric wires, and can be obtained from electrical contractors or dealers in electric wires, in the form of a roll of tape $\frac{1}{4}$ inch or $\frac{3}{8}$ inch wide. I have generally used $\frac{1}{4}$ inch wide, but this year I have some $\frac{3}{8}$ inch, but I think $\frac{1}{4}$ inch is better for very small stocks, and equally good for larger ones. I first tried it in 1896, and, after experimenting with it for a year or two, I found it so successful that I always use it now for grafting on small stocks, but it is not so suitable for crown grafting on large stocks. The graft may be cut to fit the stock in any of the usual ways, but accurate fitting is not so important as with other covering materials, as the rubber strip can be wound on tighter than any non-elastic material, forcing the scion and stock into close contact with a uniform firm pressure without cutting into the bark. The rubber strip must be well stretched before putting on, then wound round the joint tightly, so as to cover it from end to end with two or three layers of strip; it then forms an air-tight covering and holds the graft very firmly, so that no other support is required, and yet it will give as the union of the scion and stock swells. The end of the strip may be tied, but the best way is to moisten the end with rubber solution and stick it down. If very little solution is used it will stick at once if pressed down firmly; if too much solution is used it takes a little longer to set. Sometimes the rubber strip perishes quickly if exposed to hot sun, and I have lost some grafts from the rubber coming off before the graft had united properly. Last year I covered the rubber with a layer of raffia, put on loosely, as a protection from sun, and found it quite satisfactory. I have found the same material superior to anything else for budding fruit-trees, but Rose-stocks are often not strong enough to stand the strain of winding it on tightly. About 4 inches or 5 inches, measured before stretching, is enough for most grafts on young stocks, and rather less will do for very small stocks. Strip $\frac{1}{4}$ inch wide weighs about 100 grains to the yard, so that 1 oz. is enough for about forty grafts.

Heworth, Launceston. R. B. ROGERS.

FRUIT-TREE STOCKS.

In the course of a very practical lecture, delivered the other day in my hearing, on the subject of "Fruit-tree Stocks," the lecturer did not refer to a practice adopted by that excellent gardener, Mr. W. Crump, of Madresfield Court, who, having charge of a large nursery on Lord Beauchamp's estate, established specially to supply tenants with various fruit-trees, raises his own stocks almost exclusively, and in relation to all seedling ones, whether of Apple, Pear, Plum, or Cherry, corrects the natural tendency on the part of all these stocks to send down stray vertical roots to the soil. His practice is to, early in the stage of root development and when the

seedlings are planted out whilst young, and are plastic, to bend forward or horizontally the inevitable tap-roots, and thus literally set the trees upon them. The result, Mr. Crump states, is that not only are downward roots thus checked, but they become surface roots, thus enabling the trees to make good growth without producing sappy wood, and also enabling all roots to be preserved rather than bent away. To a request for reasons why not rather cut away these tap-roots, Mr. Crump replied that if such a course be taken it is pretty certain that from just above the severance new and strong vertical roots will break down, and thus in a few years the condition of the trees will be no better than would be the case had the original tap-roots been left uncut.

Trees that have been worked on stocks raised from seed, and have had their roots bent or deflected on the Madresfield lines, are, when lifted for sending out from the nursery, found to have so set a base that they will stand on the ground without support. This is strong proof of the value of the plan as applied to all free or seed raised stocks for fruit-trees. But the Madresfield trees are raised chiefly for orchard culture. Still, the plan of bending the roots answers admirably for trees to be grown in gardens, although to produce Apple, bush, and Pear pyramids, without doubt, it is best to work on Paradise and Quince-stocks. In relation to the latter stocks the lecturer approved of the practice of

DOUBLE WORKING in the case of varieties of Pears that were not strong growers. It seems strange that the introduction of but a few inches of stem of a strong growing variety between the stock and the ultimate graft should have on the latter so marked an effect as usually found to result. There is, perhaps, no better variety of Pear for first working as a strong grower than is Baurré d'Amanlis. That usually produces the first year from the bud tall shoots. These, the following August, can be budded 6 inches above the first budding joint, and when the variety is a habitually weak grower on the Quince, the result is material strengthening and much greater robustness. Marie Louise so double worked does remarkably well as a cordon on the Quince, and other moderate growing varieties respond in the same way. Of course it may be said, why not work these varieties on these seedling Pear-stocks at once? That is a fair query to put, but there is, I think, that no matter what the variety worked, the free Pear-stock will all the same tend to develop strong vertical roots, and to secure good high flavoured fruit that course should be avoided. Hence the value of double working the Quince-stock to produce trees better for garden culture.

In relation to Plum and Cherry-stocks, the lecturer preferred those raised from seed to any obtained in the form of suckers. The latter seldom produced satisfactory roots or trees. Whilst the Mussel Plum was that most widely used, the Myrobalan stock was sometimes useful for comparatively weak growers. But this stock is a coarse rooter and a late grower, hence it is less fitted for garden work than is the Mussel. What the Paradise and Quince

stocks are to the Apple and Pear, the Mahaleb stock is pretty much to the Cherry. It is well suited to produce bush-trees for the garden or cordons for walls, whilst for ordinary standards in orchards none are better than are seedlings of the common wild Gean, as these possess good enduring properties. Where standard Cherries do well they not only attain to great size, but also to great age.

A. D.

DISBUDDING VINES.

Will you kindly explain what dibudding of Vines is and how it is done? The buds entirely removed are so that no growth can again come? The Vines I am putting in my house are two-year-old canes, 3 feet to 10 feet long, and thicker than one's finger, having buds at from 3 inches to 7 inches apart. Should each of these buds be actually rubbed off, so as to allow the remaining buds to be about 18 inches apart? From the edge of the plate or brickwork to the earth bed I suppose all the buds must be removed? Should about 3 feet of the Vine be allowed upwards from the plate and above that cut off? I should be much obliged for this or any other information you may kindly give.—W. F.

[Dibudding is the removal of superfluous shoots of the Vine. From the joints of young Vine-rods there will often issue two or three buds. It will be at once obvious that only one of these will be necessary, therefore select the best of these and retain for the purpose of the summer, and remove the others. As your joints are so closely situated, it may be necessary to wholly remove the buds at a point bare and there to prevent crowding, but it need be remembered that the shoots are trained alternately on the right and left of the rod, which in some measure opens out the spaces as they appear on a young Vine-rod. It will thus be apparent that a rule making 18 inches the limit between the shoots would be too severe. Do not attempt to dibud the Vine below the roof trellis, but rather retain the shoots, keeping these in subjection by periodical pinchings. These favour the swelling of the stem from the ground upwards, which is such an advantage to the future Vine. Do not, on any account, use a knife at this late period, or such severe bleeding will be set up that you will be unable to check it—rather remove the swelling buds later on by hand from the extremity back to the point where you would in the natural course of events have pruned, and there will be no loss of sap to the detriment of the Vines. Some prone to the first wire of the roof-trellis; it is better to err on the side of severity than otherwise in dealing with newly-planted Vines. After they are well into leaf you can cut the nude rod back to any point desired without injury, because then the sap is absorbed by the foliage. As your Vines are strong they should, if your border is composed of suitable materials, make a correspondingly vigorous main shoot. This will be better stopped once or twice during its progress, which will have the effect of thickening out the shoot from behind the position where it is stopped. The advantage of this will be more apparent the following season. Do not attempt to fruit the young Vines this year, as this tends to cripple their future progress. Stop the lateral or side-shoots at the length of about 1 foot, and in stopping later allow an extra leaf each time, especially if they are vigorous.]

SOME GOOD CODLIN APPLES.

The term Codlin as applied to a particular section of Apples is a very old one, and is supposed by some to be derived from the word coddle—i.e., to parboil, in reference, no doubt, to their suitability for "coddling," a peculiar form of cooking necessary when preparing Apples for certain dishes. Codlins and oreem was a dish well known to and much appreciated by our forefathers, and the particular variety laid under cultivation to form the principal ingredient of this time-honoured dish was the old English Codlin. Codlins, to use the term generally, are as popular now as ever they were with cooks and housewives on account of their splendid cooking qualities, and housekeepers in large establishments prefer them to all others for the purpose of making Apple-jelly, their soft flesh and brisk, acid flavour rendering them eminently suitable for this. Other recommendations are: they are very heavy croppers, of which fact the accompanying illustration affords abundant testimony; they are also consistent bearers, as it is seldom that healthy trees fail to yield good crops yearly. Commercial fruit-growers do not regard them with such

sized tree as ones established. The fruit of this variety is large and conical, the width of the base exceeding the height in the case of well-developed specimens taken from young trees; skin, yellow, covered with reddish-brown markings on the sunny side, and sometimes heavily flushed with red. It has firm flesh, which is juicy and pleasantly acid. It is a splendid cooking Apple, and is in season from September to the end of October. Taking

LORD SUFFIELD next, this may be described as the king of the group, so noble is it in appearance. This originated near Manchester, and was named after Lord Suffield, who was at that time Lord of the Manor of Middleton, and near to which place it was raised by a handloom weaver. If this variety is grown in standard form, the trees should be planted so that they are protected from the force of high winds; otherwise, there is a risk of the crop becoming considerably damaged. The only drawback is the fact of the tree being so liable to canker on some soil, and when this assumes very serious proportions the better plan is to plant Lord Grosvenor, which is proof against this evil. When well grown the fruits attain a very large size, and average

grower such high returns when marketed, it is, nevertheless, a good market Apple. This variety originated near Ulverstone a great many years ago, and it was sent out by Mr. J. Sander, of Keswick, under the name it now bears. It is particularly hardy in constitution, and amenable to any form of training, and is a prodigious cropper. The fruits are somewhat similar in outline to Lord Suffield, but are smaller, and have the addition of several distinct lines or angles, which run from the base to the crown, this peculiarity being more intensified in some examples than others. It is in season from August and lasts to the end of October if stored.

LORD GROSVENOR, as has already been mentioned, is a good substitute for Lord Suffield, under certain conditions, and is also known and grown under the name of Jolly Beggar. It is, however, not so handsome an Apple as Lord Suffield, although equalling it in size, as it partakes of the character of Keswick Codlin in being ribbed, or having several angles on its sides, and is often much pockered round the eye. It is a clean, healthy doer, and has a distinct habit of growth, the young wood having a polished appearance and spotted with small grey dots, while the leaves are broad and of a leathery texture. Like Lord Suffield it is a remarkable cropper, and is a good Apple for market supply or for private consumption. If gathered and despatched to market in the same condition as recommended for Lord Suffield, the returns are then very satisfactory.

MANCK'S CODLIN, which, like Keswick, has been an inhabitant of kitchen gardens and orchards for a great number of years, is a thoroughly good Apple, if somewhat small, and an excellent cooker. It has a brighter appearance than any of the preceding, and in a hot summer often becomes beautifully coloured. It is seldom more than medium-sized, conical, and marked more or less with angles or lines, and the flesh, which is white, is agreeably flavoured for a cooking Apple. It comes into use in August, and, owing to the firm texture of the flesh, will, if required, keep till near the end of the year. This self-same Apple is also known under the names of Irish Pitcher and Irish Codlin, but Manck's is that most frequently used. It is a very close-growing variety, and trees of it, no matter in what form they may be trained, never attain to large proportions.

TRANSPARENT is much like Lord Suffield in appearance, but it has a more clear or transparent-looking skin, the same peculiarity being also imparted to the flesh. It is a handsome-looking Apple, particularly when its clear, yellow skin becomes flushed with crimson in a hot summer, and has been strongly recommended by some growers as being an excellent variety to grow for market. This succeeds well as a pyramid or bush, and is a first-rate early-maturing garden Apple.

DUTCH CODLIN is somewhat similar to Manck's in appearance, but grows considerably larger than it. This Apple used to be highly esteemed at one time, but it seems to be passing out of cultivation.

The above do not by any means exhaust the list of Codlin Apples, as there are the French, Royal, Nelson, and several others; but as the best, most popular, and valuable have already been enumerated, no good purpose will be served by taking up space in particularising these.

"The English Flower Garden and Home Grounds."—Thoroughly revised, with full descriptions of all the best plants, trees, and shrubs, their culture and arrangement, beautifully illustrated. Medium 8vo. 12s.; post free, 12s. 6d.
The same, in 3 vols., half bound sage green morocco—1st. History or presentation, one guinea nett. Of all booksellers, etc.

A good crop of Codlin Apples. From a photograph by Mr. F. Mason Good, Winchfield.

favour as they do other varieties which ripen about the same period, as Codlins are rather bad travellers; yet, in spite of this, there is no gainsaying the fact that no other Apple can surpass them for cooking, baking, jam or jelly making at the time they are in season. Again, the varieties are all so hardy and accommodating that they can be cultivated in any form of tree. For private gardens the bush is perhaps the best form of tree to plant, and the same may be said of modern plantations or orchards. In old orchards they are generally found in the form of tall standards, and some few growers plant them in this form at the present day.

The group comprises some fifteen varieties, of which several have been in cultivation for a great number of years. The oldest is the English Codlin, previously alluded to, but the best known of all are Lord Suffield, Lord Grosvenor, Manck's, Keswick, and, in a less degree, Transparent. The old

ENGLISH CODLIN has long been grown, but is fast dying out. At one time no garden or orchard was considered complete if it was not represented, so greatly was it esteemed. This is one of the easiest of all Apples to propagate from cuttings, and if a whole branch is sawn off and planted it will soon emit roots, and a fully

from 2½ inches to 3 inches in height, and about 2½ inches wide at the base. They have a smooth pale yellow skin, which becomes slightly flushed when fully exposed to the sun on orchard standards; flesh white, tender and juicy, with a plebeian acid flavour. It is in use from August to October, and is a first-rate Apple for cooking. Owing to the skin being delicate and tender, and therefore liable to show any mark and bruise easily, Lord Suffield is not planted so largely now as formerly for market work. Nevertheless it is a very remunerative Apple if gathered just before the fruit becomes ripe, and properly packed and forwarded to a good market for disposal. We have known fruits which have had this care realise prices averaging from £18 to £20 per ton, while in other cases some who lacked enterprise, both in seeking a good market and who would not gather until the produce was fully mature, did not realise more than one half of these figures. As a variety for private consumption it takes front rank, and it is a heavy, continuous cropper, no matter whether grown in the orchard or garden.

KESWICK CODLIN has long been in cultivation, and if not so large as the preceding, yet ranks with it as regards its cropping power and general usefulness. Although not yielding the

PLANTS AND FLOWERS.

AN OLD-FASHIONED BORDER.

The illustration shows a piece of an old-fashioned border. As the soil is rich, most hardy plants grow luxuriantly and form natural and picturesque groups, like that shown in the illustration of Summer Snowflake and Siberian Saxifrage, with some dark foliage behind them, and a bright mass of blue Forget-me-not, which had sown itself, further on.

Dunboyne, Ireland.

MABEL GAISFORD.

HARDY PLANTS FOR SPRING BORDERS.

SPRING may be roughly taken as comprising the three months of March, April, and May,

which contrasts so effectively with the deep yellow of the Daffodils. The best edging for the mixed border is, without doubt, one composed of rough, irregularly-shaped stones, through the interstices of and over which trailing plants may be grown. Of these there is a long list of charming spring-flowering subjects, such as the golden *Alyssum saxatile*, its lighter-tinted form *A. s. citrinum*, and the Sweet Alyssum (*Kryniga maritima*), with its honey-like perfume, a perennial in warm borders; *Arabis albidia*, which as early as February drapes retaining walls with a veil of white in the south-west; *Aubrietas*, in their many hues from lavender-grey to crimson and deep purple; the dead white *Cardamine trifolis*, *Iberis cornifolia*, *I. semperflorens*, and others

naturalising in open woods. The scarlet Star Anemone (*A. fulgens*) is particularly glowing in its hue, but in some gardens rapidly deteriorates, while in others it retains its vigour and free-flowering qualities for ten years or more. The well-known Poppy Anemone (*A. coronaria*), an old garden favourite, has been greatly improved of late years, the St. Brigid strain being very large and of pleasing colour. The Pasque-flower (*A. Pulsatilla*), a native of our chalky downs, with its purple-golden-stamoned blooms, is very lovely, but requires lime in the soil to do well. A ranunculoides, which bears bright yellow Buttercup-like flowers, is a little gem, and the silver-blue *A. Robinsoniana*, a variety of the common Wool Anemone, is perhaps the loveliest of all the Windflowers, but, like *A. hepatica* and its sister *A. H. angulosa*, requires porous soil and a partially shaded site to display its fullest beauty. In April the tall white Snowdrop Anemone (*A. sylvestris*) bears its white blossoms. *Chionodoxa* and *Scillas* make pretty patches of blue in the border, and the fine *Doronicum plantagineum* excels in Harpur-Croze often opens its great yellow stars as early as March, at which time in warm, sheltered gardens the stately Crown Imperial (*Fritillaria imperialis*) perfects its drooping bells of clear yellow and orange-red. In April the Prophet-flower (*Arnebia echinoides*), a pretty perennial, commences to expand its yellow blooms with purple spots on the interior of the petals, which disappear in a few days, and the Lyre-flower (*Dicentra spectabilis*) throws up its arching shoots strung with pendant pink blossoms. This plant should be placed behind a later-growing subject, which will hide it when it becomes unsightly, as it will towards the middle of the summer. The little Daisy-like *Erigeron mucronatus* generally begins to flower in April, and continues until stopped by the frost, and the more showy *E. speciosus* (also known as *Stenactis speciosa*) and its variety *superbus* carry their meads, yellow-centred flowers for almost as long a period. *Heuchera sanguinea* is attractive when bearing its coral-red spires of bloom, and in a somewhat shady and moist spot *Mertensia virginica* makes a pretty picture when holding on curved stems its soft blue flowers, but of blues there is none more beautiful than that of the Forget-me-not (*Myosotis dissitiflora*), which is especially charming when used as a carpet for the white Poet's Narcissus. The Spring Vetch (*Orobus verna*) bears its purple and pink flowers in countless numbers, and the chaste *Ranunculus emplexicaulis* expends its single white blossoms, while *Sanguinaria canadensis*, with its snowy, Crocus-like blooms, though little known, is worthy of a place in the border. The Foam-flower (*Tierella corallifolia*) makes a charming edging, and well justifies its English name when in full bloom, and the Celandine Poppy (*Stylophorum diphyllum*), with its large yellow flowers, has a handsome effect. *Triteleia uniflora*, now classed as *Milla*, a low-growing bulbous plant, is in April a mass of starry, white blossoms, and many of the Tulips are now at their best. In May, *Achillea ptarmica* fl. pl. The Pearl produces its little double-white flowers in profusion, remaining in bloom until the autumn; the hybrid *Aquilegias* display their graceful forms and soft gradations of colour; but though perennials are best treated as biennials, *Arenaria balearica* is delightful, spanning a large stone in the edging with a tracery of tiny white blossoms, and *A. montana* takes the place of the earlier-flowering *Arabis* on the margin of the border. *Campanula glomerata* opens its deep-purple blooms, and the scarlet *Geum coccineum* and brilliant orange *G. Heldreichii* show their glowing tints.

Group of hardy plants in an Irish garden. From a photograph by Miss Mabel Gaisford, The Grove, Dunboyne, Co. Meath, Ireland.

and, although during that period hardy flowers for adorning the open borders are not so plentiful as they become in summer days, there are yet many available to interest and charm the eye. Of these, the family of Daffodils provides a host in themselves, and, though the numerous species and varieties undoubtedly present the most satisfying picture when boldly naturalised on the Grass, many of them, from the giant trumpet form to the pretty triandrus pulchellus, add much to the beauty of the border, especially the golden varieties of the former section when planted amongst herbaceous Perennials, the rich carmine of whose young

of the same family, the Sea Pinks (*Armeria*), *Dryas octopetala*, *Gentiana acaulis*, and *Pinkie* in variety; while in late spring and early summer the *Helianthemum* or Sun Roses in different colours make a brilliant display. In March, the pretty *Adonis vernalis* opens the first of its single yellow flowers above its fennel-like leafage, preceded, however, by the newly-introduced *A. amurensis*. Anemones gladden the spring months with their lovely flowers, the Greek Windflower (*A. blanda*) often expanding its blossoms as early as January, followed later by the charming *A. pennina*, with flowers of a lighter blue, a species well adapted for

The Dey Lilies are a lovely race of plants, whose flowers, although not lasting, are produced in such quantities that an attractive display is afforded for some time. Among the best are the clear yellow *Hemerocallis flava*, the darker *H. Middendorfi*, the lower-growing *H. Dumortieri*, the tall, orange-buff *H. aurantiaca major* and *H. Kwanso* fol. var., the latter being also a very effective foliage plant. Irises, towards the end of May, are as lovely as any of our garden flowers. Of the bulbous section, the Spanish (*I. xiphium*) and English (*I. xiphoides*) are best suited for the border. These should be planted in good-sized clumps of one colour; when colours are mixed or splashed varieties

employed, the effect is trivial and unsatisfactory. Flag or German Irises are noble flowers that should be in every garden. There are countless named varieties, of which the following ten form a good selection: Florentina and Princess of Wales (white), aurea (golden-yellow), flavescens (light yellow), atropurpurea (deep purple), Bridesmaid (white and blue), Mme. Chereau (white and lavender), Victorine (white and violet), Queen of the May (rosy-lilac), and pallida (lavender). *Incarvillea Delavayi* is a handsome plant of recent introduction that does well in the border. It throws up a flower-spike 2 feet in height bearing many large rose-pink flowers and blooms at the end of May or early in June. Lilies of the Valley should be granted a nook amongst the taller subjects, and if well fed succeed admirably in full sunshine. The great Paeonies of the herbaceous and tree sections are among the chief attractions of the garden—the doubles with their massive blossoms, and the singles with their delicately graceful flowers. When purchasing herbaceous Paeonies it should be remembered that the best time for planting is the middle of September, and that they appreciate deep and rich soil. The giant Oriental Poppies strike the highest note of colour in the garden at the end of May, the vivid vermilion of their huge blossoms blazing with unrivalled splendour in the sunshine. Solomon's Seal (*Polygonatum*) is a charming plant for a shady spot in the border, and *Thermopsis montana*, with its yellow pea-like flowers, is a distinct and attractive perennial for the garden.

S. W. F.

CLEMATISES FROM SEED.

(REPLY TO "A. S.")

GENERALLY speaking, as far as the amateur and gardener are concerned, the raising of the Clematis from seed is almost, if not entirely, overlooked. It is difficult to understand why raising from seed should be so ignored, for few plants are capable of yielding such satisfactory results as these. This is more than ever apparent if a little care be exercised at flowering time in hybridising the blooms by keeping the varieties within their own section or division. Some may perhaps regard the raising of such things from seed as unnecessary, seeing how many good kinds exist among the named varieties. This fact, however, should deter no one from raising a batch of seedlings occasionally, if only for the embellishment of the shrubbery or woodland garden, for it should always be borne in mind that we have none too many of such beautiful climbers in our gardens, and, moreover, that however unworthy the seedlings may be when compared with the best named kinds now in cultivation, very few indeed would be unworthy a place in the garden. Many of the seedlings, while devoid of the florist's idea of form or insufficient substance of petal, have very good flowers, and many are possessed of great freedom of blooming. Any varieties possessed of the latter quality are certainly worth a place at the base of many a disfigured *Arenaria* or *Wellingtonia*, among whose branches these seedling Clematisses might ramble to their heart's content. As a rule, our gardeners are by no means overdone with free-flowering climbers, so that there are abundant room and opportunity for planting seedling Clematisses with a free hand.

Seeds may easily be obtained in any garden where a few kinds already exist either by fertilising with their own pollen or by hybridising wherever opportunity offers. Frequently in hot summers a batch of seed may be obtained without this assistance. Very often the seedlings are more vigorous than the grafted plants and less fear exists of breaking them, and for these reasons they are better suited for planting freely in the places mentioned. With the best-named kinds in the more prominent parts, the seedlings could be employed wherever an opportunity offered. Seeds are easily secured where a few varieties exist, and it is by no means a rare occurrence to get a score of good seeds from a single head. With these beautiful climbing plants there is no waiting half-a-dozen years for the result, for if the seeds are sown in a cold-frame in the late autumn as soon as harvested the plants would be fit for planting in May following and would flower in the year ensuing. Any seed sown in the early spring-time should be raised under glass in slight warmth,

always, however, placing the young plants in frames as soon as they are a few inches high. In planting out the seedlings, previously well started in pots, always give them the benefit of a good strong stake. When planting in the woodland or near some disfigured tree, dig out a large hole and refill with a barrowful of good rich soil. Near trees or in the shrubbery the soil will be much spent, and unless a good start is given them the newly-planted Clematisses will not make much headway.

OLD-TIME GARDEN FLOWERS.

OLD-TIME flowers and old-time gardens are not entirely things of the past, for we see instances to-day of a desire on the part of many to cultivate plants, and model, as it were, their gardens after the fashion in vogue long ago. One calls to mind places where the gravelled and stone walks are yet divided with trim Box edgings, or that equally old thing, Thrift, where Yew, out into all manner of shapes, reveal to us something of the taste which, several decades since, than obtained. As I write, my memory reverts to a west country garden where, on the terrace, a sundial still stands, an object more or less of curiosity, a relic of the past, not to be parted with any more than the specimens of Sheraton furniture in the old drawing-room overlooking the lawn, where summer arbours, embowered with Roses and other climbers, and rough timbered but cosy-looking seats at convenient corners or beneath overhanging trees, are still in keeping with the quaint surroundings. It is interesting to notice the change of opinion time has brought about. Some readers will, doubtless, recollect how, for a long season, the carpet bedding style of gardening spread like some contagion and seemed to take precedence of everything, when design and pattern appeared to be the chief points aimed at, and plants themselves cramped and pinched to such an extent in order to conform to some pre-arranged plan. And so it came about that, during this period, numerous hardy and herbaceous plants, which could not possibly be brought into requisition for the purpose named, were forsaken, and had to give place to summer bedders, some of which were in preparation months under glass for a brilliant but brief display out-of-doors. Whilst one has no wish to revert to the ideas of our predecessors in the matter of tree mutilation, we may, I think, imitate them in giving to hardy plants their rightful place in our gardens. Happily, to-day, the flowing tide is towards a more extended cultivation of hardy plants, and this revolution has not, in my judgment, come any too soon. Amongst them are many which we may rightly claim as "old-time garden flowers," and it is a matter for regret that they should ever have fallen into disrepute.

In advocating growing plants for the garden, one should not, I think, lose sight of the fact that, although primarily they should be cultivated for the adornment of borders and beds, one ought also to have in view their capabilities when in bloom for indoor decoration when out. We have, I submit, those combined qualities in not a few of those hereafter mentioned, and as now one may proceed with planting, it may be opportune to consider those that give us a delightful array of blossoms from early summer until winter's keenness puts an end to outdoor flowers. Let us, then, first of all, study our requirements before beginning to plant. For the back rows of borders, margins of shrubberies, and other places where tall-growing subjects are needed, one should remember *Delphiniums*, *Campanulas*, like *grandis* and *grandis alba*, with the double-white Peach-leaved Bellflower, *C. persicifolia alba plena*; *Phloxes* of various sorts, *Lupinus*, as *L. polyphyllus* (hush-purple), also the white form; *Spiraea anteboides*, *Starworts* for late autumn blooming, *Helianthus*, showy *Solidagos*, and *Rudbeckias*. For general border work one must also consider *Paeonies*—most brilliant of our old-fashioned flowers—*Inulas*, and the *Perennial Peas* (*Lathyruses*), *Diostryas*, *Galegas*, *Eryngiums*, and *Iberias*. Few bulbous plants offer a display so varied and for so long a time as do the *Irises*, *germanica*, *Kämpfers*, *florentina*, and *sibirica*, some of which are most effective for indoor decorative uses after being cut. *Perennial Corollifers*, of which *Centaurea montana sibirica* is an old sort, are valuable in a cut state. Let me also remind readers of Sweet

Williams, *Rockets*, and *Pinks*, the last still one of the sweetest of early summer flowers; of *Polemoniums*, like *P. Richardsoni*, a blue flower, also coming into full beauty in May and June. The *Scabiosas* and *Pyrethrums* are both good border plants, the latter in much demand for cutting. Fair Maids of France (*Ranunculus acutilobus*) and the *Globe Ranunculus*, with its yellow variety, *Trollius Orange Globe*, are both adapted for culture on borders where the soil is deep and rich, and where there is some shade for part of the day. *Columbines* have always been associated with old-time flowers, and are very interesting. *Anemones* are charming, and some of the spring-blooming sorts, like *fulgens*, as well as those that flower in late autumn, as *japonica* and *j. alba*, should be included in every collection of hardy flowers. Charming, too, are the *Gentians*, from the small-flowered *G. verna*, which delights to grow amid rocks and stones, and never seems better than when on some sunny rockery, to the old *acaulis* of our gardens. Where blue flowers are wanted these are sure to command admiration, being dwarf and pretty. These one cannot afford to do without the brilliancy of the *Poppies*, and those of the Oriental type are extremely showy. *Liliums*, too, grouped about a garden have a very pretty effect. We see this in early summer, where *candidum* is planted. The *Torch Lilies*, of which we select one example, viz., *Kniphofia grandis*, are among the showiest of our old-time flowers, and still are largely grown. For a cool, moist soil mention may be made of the *Day Lilies*, the *Hemerocallis*. On a sunny bed, *Alatromerizas*, *Gaillardias*, and *Lunaria* (*Honesty*) may be successfully undertaken, whilst for early summer flowering *Doronicums* and *Fritillarias*—*Crown Imperials*—are worth noting. One plant I had almost overlooked is the *Erigeron*, all the varieties of which are of much use where quantities of cut blooms are desired, and one of the many bulbous plants one cannot afford to leave out the *Galtonia* (*Hyacinthus candicans*), inasmuch as they are imposing when in bloom in July and August, their white bell flowers being somewhat conspicuous amongst *Gladioli* and other showy flowers then with us.

Whether we are disposed to regard hardy plants in the light of the ever-changing display, or value them most for the variety of blossoms they supply us with suitable for cutting, we cannot, I think—at any rate, those of us who have grown them—but admit that no class of summer bedding plants, however brilliant a pageant they afford, can compare with some that we still care to designate "old-time garden flowers." WOODBASTWICK.

MONTBRETIAS.

THESE beautiful flowers, which have been much improved of late, should be grown in every garden. They are very hardy and well adapted for growing in the wild garden and shrubbery borders, also by the margins of streams. When planted in such positions, however, some of the old soil must be removed and replaced with a mixture of loamy soil, well decomposed manure, and a little leaf-mould. They do best when grown in a sunny position and given ample room. The corms are sometimes left in the ground for two years, but this is a mistake, as the plants then become crowded, and the bloom-spikes are small and poor in quality. The corms should be taken up every year in March, divided and replanted, the large ones 6 inches apart, in rows 15 inches apart. The soil should be deep and fairly rich, and contain a liberal quantity of leaf-mould. Plant the corms firmly about 2 inches deep, and in May mulch the spaces between the rows with old mushroom-bed-mansure or leaf refuse, as *Montbretias*, being free-rooting plants, require plenty of moisture. A good mulching with diluted liquid-manure once in three weeks is of immense benefit to them. Do not allow exhausted flowers to remain on the plants, or they will soon impoverish them. The small corms should be planted by themselves and closer together than the large ones. If kept well watered they will make good flowering corms for next season. *Montbretias* are invaluable for cutting, and look charming arranged in vases with a little of their own foliage. They should be placed in a cool room, and the water changed occasionally. The following are all charming varieties: *Bouquet*

Parfait, bright vermilion, with yellow centre; Crocaminiflora, scarlet and yellow, very fine; Drap d'Or, rich yellow; Pottsi, orange and scarlet; Etoile de Feu, bright vermilion, with deep yellow centre; Transcendant, orange shaded outside, inside yellow, a very free-flowering variety; and Germania, a fine new variety. J.

CLIMBERS FOR A WALL-BACKED HERBACEOUS BORDER.

The photograph reproduced on this page shows the best form of mixed border—namely, one backed by a high wall. The wall in question is apparently of recent date, as it is only at rare

rarely met with in this country. Climbing Roses are a host in themselves, but these are treated of more fully in another article. The Clematis family affords a large selection of species and varieties suitable for wall climbers. The first to bloom is *C. balcarica* or *calyculus*, which, in the south-west, bears its white, purple-spotted flowers in February. At the commencement of June the well-known *C. montana* is smothered in its starry, ivory-white blossoms, and, in the autumn, the yellow-flowered *C. graveolens* blooms, as well as the fragrant Virgin's Bower (*C. Flammula*), and the well-known *C. paniculata*. The large-flowered Clematises of the Jackman, lanuginosa, petens, and floride sections prodnce their widespread

myriad snowy blossoms being norivalled. This is deservedly a favourite with cottagers who hold sweet-scented flowers in high estimation. *Bignonia* (*Tecoma*) *radicans* is a brilliant sight when thickly set with its orange-scarlet blossoms, and other species of *Bignonia* are well adapted to outdoor culture in the south-west, where *Solanum jasminoides* bears its white bloom-clusters through eight months out of the twelve, the fragrant *Stauntonia latifolia* its inconspicuous flowers in the earliest days of spring, and the *Lapegerias*, on north walls, their drooping, waxy blossoms of red and white till Christmas-tide, *Physianthus albens* its crowded white blossoms, and *Akebia quinata* its odorous maroon-coloured flowers. The five latter plants cannot, however, be considered hardy in more northerly counties. Of annual flowering climbers, or climbers that must be treated as annuals, we have *Cobaea scandens*, with its large purple bells, the pink-flowered *Lophospermum scandens*, the Canary Creeper (*Tropaeolum canariensis*), climbing *Tropaeolum* of the *Lobbianum* section, and the scarlet and yellow *Mimulus lobata*. In favoured localities in South Devon and Cornwall Ivy-leaved *Pelargoniums* are rarely injured during the winter, and such plants as *Solanum Wendlandi*, *Hidalgos Wercklei*, *Mandevilla suevoles*, *Gianthus puniceus*, and *Mutisia decurrens* succeed against the open wall. All the subjects mentioned in this note are suited for covering a high wall at the back of a herbaceous border, though some, as pointed out, are not sufficiently hardy for cold localities. Some require the assistance of wire to enclose the wall, and some are of such rampant growth as to need periodical thinning. In the accompanying illustration the value of fine form in the garden is shown in the effect produced by the lofty gray Mullein (*Verbascum*) and the foliage of the Flag Iris and *Saxifraga cordifolia*, while the tall *Thalictrum aquilegifolium* in the foreground, the Sea Pink, Sunroses, and other flowers in the middle distance, and the informal manner in which the edging plants have strayed in irregular breadth into the pathway, combine in rendering the border a pleasing example of natural beauty. S. W. F.

A wall-backed hardy plant border. From a photograph by Miss Willmott, Warley, Essex.

NOTES AND REPLIES.

The distillation of flowers.—I am very desirous of trying the home distillation of flowers. Could some reader kindly give me some information on the subject? I have a copper still for ordinary kitchen use, and the flowers available are Roses, Lavender, and Elder. The information required is mostly as to proportions and treatment of the flowers.—*Distill.*

Increasing Eryngium.—Will you kindly inform me what is the best way to propagate *Eryngium*? I do not find dividing a very successful way, as only a few start, so I think that root cuttings will be the best. Kindly say if that is so, and if so, how and when will be best to put them in? The method you recommended of propagating *Senecio pulcher* I have found very successful.—*W. Terr.*

[You do not say which species you inquire about, and there is considerable difference. The biennial kinds, as *E. serra* and *E. pandanifolium*, are easily raised from seeds, but they are scarcely hardy enough for British gardens generally. Many of the perennial kinds are quite easily raised from seeds also, and all may be increased by root cuttings. The best roots are those below the first thong, or about 8 inches from the crown. At this point you may sever what you require and replant the crown portions at once. The present is a good time for these root cuttings of not a few things, and none come more freely or ready than of the genus under notice. What you have to do is to cut the roots into lengths an inch long, or rather more, keeping the upper part always as forming the top. When you have sufficient made, insert them around the interior of some class well-drained pots, using sandy soil. By placing the cuttings not quite close together you may get from four to five dozen around a pot 8 inches in diameter. The best plan is first to place in enough soil so that the root portions when inserted just clear the surface rim of the pot, then stand the root cuttings in this surface soil and lean against the pot. When the pot is filled around, fill the centre with soil, and make firm and well water. Placed in the greenhouse in

Original from

intervals, here and there, that climbing plants thread its surface. Every wall-backed border should have the wall surface covered with flowering climbers, since these provide the most charming background possible for the herbaceous plants in the bed beneath. The list of flowering climbers, both perennial and annual, suitable for such a wall is a long one, and includes many flowers of conspicuous beauty. The *Wistaria* is admirably adapted for such a wall, old specimens being met with that have extended 70 feet and more along wall-coatings, where they are objects of especial loveliness when adorned with their countless long tassels of scented, lavender blossoms. The variety *multijuga*, with racemes sometimes as much as 3 feet in length, is extremely beautiful, but

blooms, single and double, through the summer and autumn, while the seldom-seen *C. coccinea* creates a brilliant effect with its scarlet blossoms. The common blue *Paeonia*-flower and its white variety *Constance Elliot* are fast-growing climbers that are practically evergreen, only losing their leaves when the young foliage is being pushed out in the spring. They are very ornamental during the summer with their large, star-shaped blossoms, and enjoy a further period of beauty in late autumn and early winter when thickly hung with oval fruits of glowing orange that gleam brightly under the dark skies from out the dark green leafage. *Honeysuckles* in variety are always welcome, and the white *Jasmin*, though common, can scarcely be overrated, the exquisite perfume of its

slight heat growth buds will appear in about a month at this season of the year. With greater progress the young plants may be treated in the usual way.]

Bulbs for border.—I shall be much obliged for your advice regarding a long, narrow border (at present thickly planted with spring bulbs)? It has a Box-hedge (low) at the back (W.), and practically gets little sun, but this has a very hot, dry soil (sandy). I want the names of bulbs for making a show in July and August. I have Gladioli. What Lilies would do well?—H. C.

[In Lilies you have a large selection, and you may practically plant any kinds of which you can now obtain good bulbs. For example, any of the forms of *L. Thunbergianum* would be excellent, and equally good are such as *L. croceum*, *L. nimbellatum* and *davuricum*, *L. Batemannii*, *L. longiflorum coccineum*, the lovely *L. auratum*, *L. tigrinum* in all its varieties, and, finally, the great host of beautiful things found under *Lilium speciosum*. These last, however, do not flower before September. In their stead you may plant *Alstromeria aurea*, *A. psittacina*, *A. chilensis*, etc., also any of the best *Montbretia*, and *Galetia candicans*. Then there is *Tigridia*, a rather showy, important group delighting in sun and warm soil. The majority of the Lilies named, excepting *L. auratum*, should succeed, and even this on occasion does not object to quite strong sun, provided the soil below is fairly deep. You say you have Gladioli. Do these include the newer race known as *Lemoinei* and *Childsi*, etc.? These embrace some really fine forms and quaint colours, and are more hardy.]

Tall v. dwarf Wallflowers for early blooming.—Amongst early-blooming hardy flowers Wallflowers hold an important place. Many growers have a special strain, and when grown in the open fields the plants are not very tall. Where they are needed for gathering from early in the year the very dwarf kinds so useful for planting in beds for spring gardening are not suitable, seeing they do not commence to bloom early compared to the taller-growing kinds, of which *Harbinger* is a type. Some years ago I had a good strain of this kind, and when planted in a sheltered border, facing west, in front of my cottage, I was able to gather handfuls of bloom during January, while the dwarf yellows and reds were not in bloom till the end of March. Last year, when at Bourne-mouth at the end of March, I observed the dwarf kinds had scarcely a bloom open.—J. CROOK.

Calceolarias under hand-glasses.—After a protracted winter, with several spells of sudden and severe frost, I was surprised to find a splendid lot of yellow and dark Calceolarias that had stood without any covering beyond some cloches and hand-glasses, that were set on a border in the autumn and filled with cuttings and kept quite close, but never opened or removed until the end of February. All the cuttings had made sturdy-looking dwarf plants that needed a little more space to develop into fine sturdy bushes; in fact, far better than the ordinary run of plants one finds at this time of year that have been grown in pits or frames.—J. G., Gosport.

The New Zealand Flax (Phormium tenax) in the open air.—Some ten years ago I had some plants in pots raised from seed brought home by the owner of this garden. These I planted out in two positions, one on low ground, near an ornamental pond, and exposed to north-east; the other was on some high ground 20 feet above the other close by. These are sheltered by a big mass of evergreen shrubs; the soil here is dry. In this position they do not grow nearly so fast as those near the water, but every summer they all bloom. In one severe winter those in the damp situation suffered slightly, but soon recovered. I should not hesitate to plant out *Phormium tenax* except in the coldest parts of the country. Many things that would thrive in the open suffer from being cramped in pots.—J. CROOK, *Ferde Abbey, Chard.*

Raising Eremuri from seed.—Good fresh seed sown as soon as ripe in a pan of light soil and set out in the open will begin germinating in less than a month, and the tiny spars will continue piercing through the earth till all have come up. The pan should be wintered in a cold-frame, but it will soon be observed that many of the young plants are ripening off. One would imagine something

was wrong, but all is going well, the season of life above ground the first year lasting only a month or two. About May the small fleshy roots may be taken out of the pan and planted in a bed of sandy soil where protection in the severest weather may be given in winter. Each year the young plants ripen off their leaves later and start to grow later than they did in the first year or so of their existence. Every summer they should be transplanted till about the eighth season after sowing the blooming stage will have arrived. The first two years the roots go straight down, but after that they assume a horizontal growth and radiate from the crown. New roots are formed every year, the old ones decaying and falling away.

Cold frames in April.—Perhaps at no other time in the year is it needful to watch more closely the inmates of cold-frames, whether they contain *Pansies*, *Anriculias*, *Calceolarias*, or other partially hardy subjects, than during the month of April. We often get bright spells of sunshine, which necessitate sometimes the shading of the plants in the frame or the removal of some where they have been placed too closely at first, as in the case of *Pansies* and *Calceolarias*, as to leave them too long together they become weak and lanky, spoiling each other from want of space. Where such conditions exist it is worth the trouble to remove some, if one has to sacrifice a few, rather than spoil the whole.—LEAHFRST.

Renovating Grass plots.—The lawn should now receive attention. How seldom, indeed, one thinks of Grass plots after the lawnmower was put away until it is time to attend to the duty again. How few consider the plot as requiring manure, and yet, after all, a little trouble spent in this direction is seen in fewer bare patches. Now is the time to make good any defects, and it is even worth while to spread over the surface some half-rotted dung, so that the rains may do their part, and any relaying of turf is best undertaken during this month. Seed may be sown early in April.—DERBY.

ROSES.

PLANTING A NEW BORDER OF ROSES. (REPLY TO "WILD GARDENER.")

We quite agree with you that the beautiful Tea Roses may be grown most satisfactorily upon roots, as you describe, and where exhibition bloom is not desired they do not require much pruning, provided they escape injury from frost. We note your intention to plant Tea Roses upon what you term "moots," but as you ask for information regarding *Aglaia* and other "Rambler," we conclude your intention is also to plant some of this class. Twelve first-rate fast-growing climbers are *Aglaia*, or *Yellow Rambler*. This is very beautiful, but requires patience in its treatment. If left unpruned and allowed to ramble at will it makes a glorious show about the third year after planting. *Electra*, which is newer and very similar, flowers freely the summer following the planting if not pruned in any way. Doubtless you have *Crimson Rambler*, otherwise this would be indispensable. *Euphrosyne* (*Pink Rambler*) and *Thalia* (*White Rambler*) are most beautiful, but the remarks regarding *Aglaia* apply also to these two. Two hybrids of *Rosa Wichuriana* are particularly lovely—namely, *Jersey Beauty* and *Ruby Queen*, both excellent ramblers. *Carmine Pillar* is good, also *Rosa sinica Anemone*, *Mme. Alfred Carriere*, *Reine Olga de Wurtemberg*, *Mme. Jules Siegfried*, and *Dr. Ronges*. The above would be a varied and excellent dozen ramblers. For the hedges between the roots and "moots," Japanese Roses and Scotch Roses, as suggested by you, are very suitable. As you desire the names of fifty of the very best exhibition Roses, you should write to Mr. Edward Mawley, hon. secretary of the National Rose Society. As to the arrangement, we think half circles of contrasting colours, composed of the strongest growers, and running the whole length of the border, would have a good effect, and in front of each half circle a hook or clump say of three or four plants of one variety, but of a more lowly growth, could be placed, and these of a different colour. This would have a better effect than straight lines. The angles in front could be planted with one plant of a dwarf-growing kind, or with *Tufted Escalopes*

and at back we presume you could arrange the angles to be opposite the "moots" or roots. The distance at which these Roses may be planted would be 1½ feet apart for the dwarfest growing, and about 2 feet apart for the stronger. If you aim at exhibition blooms you would need to prune more severely than if you were growing the Roses for merely garden decoration.

NOTES AND REPLIES.

Rose Marechal Niel planted last autumn.—Last autumn I purchased a *Marechal Niel* Rose. It was in a 7-inch or 8 inch pot. It has two vigorous, strong shoots or branches, one about 9 feet, the other about 14 feet long. I have planted it in a cold-house. Should either or both of the shoots be shortened? It has plenty of wire to run on. I want Roses as it is this year, and would thank you to inform me whether I could let it remain as it now is, or prune?—J. B.

[This fine plant, with growths 9 feet to 14 feet long, will require but little pruning now. Generally speaking such plants have 1 foot to 2 feet of unripened wood at the extreme ends of the growths, and by removing this the more eyes below are induced to break and provide blossom. Another good plan is to train the growths of such plants around three sticks, then almost every eye will break. This, of course, can best be done when the plant is allowed to remain in the pot. It is not a good plan to suffer too many blossoms to develop on one plant. A judicious thinning of the buds will assist those that remain. Often this popular Rose is over-cropped and over-fed. Feeding is needful as buds increase in size, commencing when about the size of Peas, but it is better to give it weak and often. We have found liquid-manure made from cow and sheep manure most beneficial, and a peck bag of soot dropped in the liquid-manure barrel is also valuable.]

Rose cuttings under glass bottles.—I followed the instructions given some months ago in your valuable paper for striking Rose cuttings under glass bottles. I am pleased to say at least 75 per cent. have rooted. I should like to know when is the time to take the bottles, when is the best time to put the Roses into permanent quarters? I should prefer November or March. Should the trench be left as it is when the bottles are removed, or filled up? If filled up it would cause the trees to be buried. If necessary, I could take them up in the autumn and put them in a cold-frame.—HAGLEY.

[We are glad to learn from you that the method of striking Rose cuttings advocated in these pages in our issue of July 7th, 1900, has in your case proved so successful. If you do not require the ground now occupied by the cuttings we should advise you to leave them where they are until next year, transplanting them to permanent positions in March or April. The glass bottles should not be removed this year until May. When this is done draw away the soil, leaving the plants free in the trench. A small stick should be placed again; each cutting and the growths tied upright. In June a thin mulching of well rotted manure and old potting soil would considerably strengthen the growths. Should you desire to transplant this spring you can do so in May; but in this case pot up the plants into small pots for three or four weeks and plant out during showery weather in June. Of course the plants after potting must be kept in a cold frame. After you remove the bottles in May it is as well to watch against frost. It would be a simple matter to cover the cuttings every night until all danger of frost is over.]

Rose W. A. Richardson.—I have often noticed in your columns that this Rose has a name for "producing pale-coloured blooms." While allowing this to be true, may I ask your correspondents if they have noticed that if the cuttings are taken from rather old, well-ripened wood the colour will be everything that can be desired; if, on the contrary, the cuttings be from young, rather tender wood, the blooms of the plant will be always paler, and no feeding or care will make them otherwise. I have struck as many as twenty of them in one season, and have noticed this peculiarity year after year. If more pains were taken in selecting the wood for the cuttings this lovely Rose might lose the reputation for "pale-coloured blooms."—H. M. B.

As many of the most interesting notes and articles in "GARDENING" from the very beginning have come from its readers, we offer each week a copy of the latest edition of either "STOVE AND GREENHOUSE PLANTS," or "THE ENGLISH FLOWER GARDEN," to the reader of the most useful or interesting letter or short article published in the current week's issue, which will be marked thus:—

ROOM AND WINDOW.

COSMOS.

THE genus *Cosmos* numbers only about ten species, and as these are mostly natives of tropical America, Mexico, etc., the best time to sow is after all danger of frost is past in spring; indeed, it is never safe to sow *Cosmos bipinnatus* until April. Of all the species, none are so beautiful as *C. bipinnatus*, here figured. A glance at our illustration will give some idea of the beauty of this charming annual, which, as a fine-foliaged plant, is the most elegant of all annuals. It grows to a height of from 3 feet to 5 feet, copiously branched and well clothed with delicate thread-like leaflets. The Hibiscus-like bright red-purple blossoms, which in warm summers are freely borne on long foot-stalks, are very useful for cutting. If one wants an early display a good plan is to sow in pots in a warm-frame in March, and a week before planting to stand them in a cold-frame to harden off, finally potting into their flowering quarters, 2 feet apart. A good way to obtain a

settling last but a short time when out. They can be made to last in capital condition for five or six days at the least if the precaution is taken to cut the bracts the day before they are required, and steep the stems all night in a bucket of water, placing the latter in the house in which they have been grown. Another method, and a very excellent one when the bracts are required at short notice, is to plunge the ends of the stems in boiling water, which effectually seals up the pores of the wood and prevents further flow of the "milky" fluid or juices, the draining away or loss of which is accountable for the flagging of the bracts when they are used in heated rooms. I have been using *Poinsettias* treated in this way for some time past, and with most excellent results.—A. W.

CHRYSANTHEMUMS.

SEASONABLE NOTES ON CHRYSANTHEMUMS.

MUCH may be done at this season to ensure the well-being of the young plants. Growth of a

prove that the cold-frame, for plants rooted early in the year, is the only accommodation suited to their needs at this season. Assuming the plants were rooted singly in "thumb"-pots they should now be in those measuring 3 inches in diameter. For a little while the pots may be arranged close together. We are not yet "out of the wood" in so far as regards sharp frosts, and at any time within the next week or two it will be necessary to provide adequate protection in the way of plenty of litter and good mats. Cold easterly and north-easterly winds are very cutting during March, and not infrequently also much later, and for this reason when giving the cold-frame hut a "crack" of air, care must be observed that the somewhat tender occupants of the frames do not suffer. It is necessary, of course, to commence inuring the young plants to harder and more airy conditions, but it will be apparent that they should be adequately protected against the cutting winds when they prevail. Through carelessness in this respect I have seen a promising batch of young plants almost spoiled, and although receiving careful treatment subsequently, they never appeared to recover from the check they then experienced. The plants must be grown on without a check from their earliest history until the blooms are out for the shows. Watering is an important item of culture even at this advanced period. The sharp bursts of sunshine very quickly dry up the moisture in the soil of the small pots, and unless one is on the alert in this respect the plants may suffer in consequence. One thorough watering when given is the rule to follow.

Plants needing their first shift even at this late date should be treated with the utmost care. Immense quantities of useful plants are propagated later than are those intended for exhibition, and many establishments now have their batches of plants, which are nicely rooted, in boxes and around the edges of some of the smaller-sized pots. These young plants should be lifted from the boxes or shaken out of the pots, and be repotted singly into small sixties (pots 3 inches in diameter). Compost for this shift should comprise three parts fibrous loam, one part leaf-soil, and one part nicely rotted horse-manure. Pass the foregoing through a sieve with a 1/2-inch mesh, and add thereto a liberal quantity of sharp sand or coarse silver-sand, and give the whole of the ingredients a thorough mixing. Use clean crocks and pots, and pot the young plants firmly. By these means growth of a sturdy character is encouraged, and if the plants be placed in a cold-frame subsequently, the sturdy growth becomes consolidated, and a good foundation thereby laid. Keep the cold-frame rather close for a few days, until the plants have recovered from the check experienced through the repotting.

E. G.

CHRYSANTHEMUM RUST.

THAT rust does exist is taken for granted, but the possibility is there are many instances where its presence passes unnoticed, or is accepted as a result of indifferent culture. Some kinds are very much more addicted to the disease than others, and though no sufficiently clear reason can be given why it is so, there are at any rate gardens where no disease appears among the plants. Instances occur, too, in which a collection has been hadly infested one year, and the next there is no disease. While, too, some growers take every precaution, and spare no effort to combat the enemy, its persistency is such that one's energy becomes almost, as it were, crushed. This has been so, at any rate, with some, and they have been driven to leave the plants to take their chances, whether for good or evil. An instance of a nurseryman who grew a great quantity for cutting for the purpose of his business, was a year or two since the victim of the disease to such an extent that almost the whole of the plants were ruined, the flowers opened in a poor, half-hearted way, and the plants lost all their foliage. This so exasperated the owner that he resolved on some drastic measures for the ensuing year. Fresh cuttings were bought in, and also a good stock of *Velthea*, a specific prepared specially for fungoid diseases, and for *Chrysanthemums* in particular. Into a solution of this the cuttings were dipped before they were inserted, and every week after until the flowering period came round they

Flowers of *Cosmos bipinnatus* in a vase. From a photograph by Geo. E. Low, Dublin.

succession is to sow seeds between these plants, and by the time the early plants are over the others will be showing flower. A light, sandy soil suits the *Cosmos* best, and the warmer the position the better will be the result.

Hardy Ferns for Rooms.—Many of the hardy Ferns are quite as well adapted for room decoration as the greenhouse kinds commonly grown for that purpose. Some beautiful varieties as the Welsh Hard Fern (*Polypodium vulgare cambricum*) and the Crested Male Fern (*Adiantum Filix-mas cristata*) are quite equal in beauty to most of the Ferns that require to be cultivated under glass throughout the year. The *Scolopendrinum*, *Polypodium*, some of the *Asplenium*, and *Polystichum* are evergreen if merely protected from the vicissitudes of our winter climate. For corridors, entrance halls, and similar places where cold draughts of air are apt to come and where the temperature will sometimes fall to freezing point, these hardy Ferns are much more suitable than greenhouse kinds.

Poinsettias flagging when cut.—One often hears the complaint that *Poinsettias* may take. These facts should

sturdy kind can only be developed by cool treatment, and for this reason, assuming the earliest batch of young plants has received the first shift, they should be arranged in the cold-frame close up to the glass. Many growers regard the treatment of young plants in a cool greenhouse as ideal at this early period, but the system will not hold good. As growth is made very rapidly at this season, particularly where there is the least amount of artificial heat, it will at once be apparent how undesirable is the character of the growth under such treatment. You may ventilate ever so freely, but you cannot prevent the young plants becoming drawn. Even in a cold greenhouse, when the plants are arranged on shelves near to the glass roof, the same danger, only in a less degree, is experienced. With the daily increasing power of the sun the temperature of all glass structures must necessarily rise considerably, and not infrequently at a very rapid rate, and with disastrous results. Sturdy growth under these conditions cannot possibly be, and unless a good foundation is laid at this early period it is almost hopeless ever to expect to produce in the end anything likely to reward us for all the trouble it may take.

were syringed with the same preparation. The result of this was a perfectly clean stock and abundance of first-class flowers in their season. Now this is a costly procedure, but in this instance it was no doubt well repaid. In some seasons and among some collections it is possible to find traces of the disease at any time of the year; in others it makes its appearance in late summer, and continues on through the winter. The cuttings, too, when taken are found with disease spots lurking about them, which develop during the period while they are kept close. The better course of dealing with them at this time of year is to pinch off the leaves so affected and burn them at once. It will often be found that the spots will be on the old leaves, the growth made beyond the original cutting being clean. If every individual plant is examined weekly during the time they occupy small pots the chances are they will go on through the summer without any trouble. Should it appear in the autumn just about or prior to their being taken indoors, a few syringings with Veltha will tend to check it greatly, if they do not stamp it out. As previously remarked, some kinds are much more prone to disease than others. A partial remedy is obvious—discard those which are the most diseased, and retain those not so addicted. It is supposed by some that high feeding contributes to this trouble, manures of a highly stimulating nature being necessary to build up the high-class exhibition flower. While this view is held by some, another grower will say the poorly-fed and weakly-grown plant is that which fosters the disease. That it does exist under both conditions has been often proved, but because this is so it must not be made an excuse to allow the disease when present to run its course unmolested. Soluble petroleum in a neat state, applied with a pointed stick or small camel-hair pencil to the rust spot, has been a remedy with some. Others, again, use the petroleum alone, but these applications are fit only for small plants which can be handled each separately. One very useful and partial remedy is to encourage the vigour by rational treatment from their early stages and throughout the growing season. A change of manure as an effort to stimulate vigour in the plants is advisable, and as manures of so many kinds are obtainable in suitable quantities cheaply, this comes within the means of everyone.

S.

Chrysanthemums—what to do with recently rooted cuttings.—At this period many growers have numerous cuttings which were propagated in shallow boxes, etc., and which have recently rooted. It is important that the young plants be potted up singly into small pots—those 3 inches in diameter or rather less—as the roots to quickly become matted and entangled that unless they are taken in hand promptly serious damage must necessarily ensue when dividing them. The soil for this potting should consist of two parts good fibrous loam, one part leaf-mould, and a half part of well-rotted horse-manure. Add thereto a liberal quantity of coarse silver-sand or clean road-grit, and thoroughly mix the whole. Both crocks and pots should be clean. Cover the crocks with the rougher siftings of the compost, and pot the young plants rather firmly. When potting is completed, either place the young plants in a cool greenhouse or in a cold frame where protection from frost can be provided. Keep the frame rather close for a day or two, after which gradually admit air, taking advantage of genial weather to give them a more abundant supply.—E. G.

Outdoor Chrysanthemums.—Border Chrysanthemums are some of the best things one can grow in a garden, particularly if the garden be near to a town, and early in April the old plants of last year—and I have many such that have withstood the winter with merely a little stable manure placed round them—will be ready for dividing. I look upon Mme. Desgrange, Mme. Marie Masse, Mrs. Hawkins, Mollere, Ivy Stark, Lady Fitzwygram, Comtesse Foucher de Cariel, and Queen of the Earlies as indispensable amongst the first to bloom. If only all admirers of this section would understand that they may be grown without any glass protection whatever, then many of our gardeners would wear a brighter aspect in the autumn.—E. G.

ORCHIDS.

CYPRIPEDIUM CALCEOLUS.

THIS has been called the English Lady's Slipper, and, indeed, is so called at the present time, but it is very doubtful if a single specimen of it could be found in a wild state in this country, even in those very few localities where once the plant was sparsely distributed. Happily, it is not extinct in other countries, and each year consignments are received in the early autumn months. These, unfortunately, are not lifted with much care by the collector, and the result is single crowns for the most part with but few root-fibres existing upon them. But even with such rough and ready treatment as this, the plants, with care, do not take unkindly to our English climate, and many may be established in due course, though failures are bound to follow now and then. Once the plants make a start at the root there is little to be feared for the fresh young fibrous roots, as these issue from immediately below the flowering crown, reach and extend a consider-

able distance when in the right kind of soil. Singularly enough, because it is an Orchid, the soil usually given is one of peat and as such soils do not suit this particular kind, not a few of the failures to grow it well or even to establish it at all may be traceable to this alone. Certainly if weakly plants and plants with but few roots to sustain them are at once planted in the worst selection of soil it is small wonder that failure results. In nature this species is only found on calcareous formations, usually in loamy soil freely impregnated with limestone chippings. To make it a success in our gardens the species should at least be planted in loamy soil, and in this, without the admixture of lime, I have grown the plant with every success. Naturally there is a certain percentage of lime in most loamy soils, and some, such as the Banstead loam, have a larger share than others. The addition of old mortar or some bone-meal will, however, assist if anyone so desires, and it may help in certain cases. Provide a deep bed, quits 18 inches deep, and make it sandy or gritty. A rather sheltered spot is good, and while some writers make a point of a well-drained and rather dry soil, I invariably plant in a recessed bed, about 3 inches below

the usual level, so that plenty of moisture is assured to the plants. Thus arranged a pretty effect may be gained by colonising the plants, as in the illustration, and once established the plants may go on for many years annually increasing in strength and general vigour. The English Lady's Slipper has a large, much-inflated lip, or labellum, of a deep yellow tone, lined with dark veins occasionally; the sepals and petals are brownish-purple. The plant flowers in May and is delicately fragrant. When well-established it will attain fully 18 inches in height. E. J.

CHIMNEY CAMPANULAS.

I HAVE a dozen of these, white. This time last year they were planted out in a cold-frame and potted up into 4-inch pots in April, on the understanding that they would flower about harvest-time. None showed any signs of bloom. I re-arranged the drainage in October and top-dressed them, putting them again in a cold-frame for the winter. Now they are little rosettes about 3 inches across. What can I do to get them to flower this season? Shall I bring them into the greenhouse, which is now between 50 degs. and 60 degs. at night, and whatever the sun chooses to make it in the day? Or should I shift them into bigger pots

Cypripedium calceolus in Mr. Goodman's garden at South Lodge, Hordham. From a photograph by Norah E. Hay, Greenocks, Brockenhurst.

able distance when in the right kind of soil. Singularly enough, because it is an Orchid, the soil usually given is one of peat and as such soils do not suit this particular kind, not a few of the failures to grow it well or even to establish it at all may be traceable to this alone. Certainly if weakly plants and plants with but few roots to sustain them are at once planted in the worst selection of soil it is small wonder that failure results. In nature this species is only found on calcareous formations, usually in loamy soil freely impregnated with limestone chippings. To make it a success in our gardens the species should at least be planted in loamy soil, and in this, without the admixture of lime, I have grown the plant with every success. Naturally there is a certain percentage of lime in most loamy soils, and some, such as the Banstead loam, have a larger share than others. The addition of old mortar or some bone-meal will, however, assist if anyone so desires, and it may help in certain cases. Provide a deep bed, quits 18 inches deep, and make it sandy or gritty. A rather sheltered spot is good, and while some writers make a point of a well-drained and rather dry soil, I invariably plant in a recessed bed, about 3 inches below

before doing so? I have another lot planted out in a frame that were sown this time last year. Surely I ought to have a show somehow?—H. M. B.

[Judging from your letter, with the first dozen of which you speak there must have been some cultural error. With good culture plants can easily be flowered in from twelve to sixteen months. By sowing the seeds now the young plants should be in 4-inch pots by the end of June. Better still, if planted in the open in deep, rich soil, 18 inches apart, or even in the frame you speak of. In either case attention must be paid to watering and feeding to build up a solid foundation. In September you may pot the plants up, or you may leave them until April, when, in the first week thereof, pot the clumps with all the roots you can get into 10 inch pots. See you have a good yet not over-abundant drainage. The soil may be any good, sound loam, with sand added; and also some old mortar. A handful of some good fertiliser will be useful. With the coming away of the flower-spikes the plants must be encouraged with liquid-manure twice each week, and at an early stage a top-dressing of richer soil. Ample water supplies are essential at this stage.

Now as to your other plants. Six-inch pots

are quite useless. These plants have been starved. You may improve them now by shaking away all the old soil and potting afresh in perfectly clean pots not less than 8 inches across, with a view to a liberal shift later on—say, first week in May. Employ very old manure, finely sifted, at the rate of one-fourth of the soil and send one-sixth. This shift may resuscitate them in a measure, and each little rosette may have its small spike of flowers. Your greenhouse at 60 degs. is rather too warm, and plenty of air will be needed. Be sure the plants do not get dry at the root. Those sown a year ago may be potted as already noted; or you may pot them now if you see they are on the move. Give them ample room, however, and keep in the cold-frame for a month longer, as you do not require them until harvest time. Pots of 10-inch diameter, with very firm potting and rich soil, and at least 1 inch retained as space for watering at the top, to be filled up each time water is required, with cool and liberal treatment, should insure you the display you expect in the coming autumn.]

NOTES AND REPLIES.

Orchid leaves falling off.—I enclose some leaves and bulbs of *Cattleya Gaskelliana* which have gone wrong, also some leaves of *Vanda concinnescens* which have fallen off. I should be much obliged if you will tell me the reason for this decay? The temperature of the house in which they are kept varies between 50 degs. and 55 degs. —C. BOLTON.

[We should say the following would be the cause: Temperature too low, probably combined with a too liberal supply of root moisture during cold periods. The temperature should not be less than 55 degs. for these species.]

Increasing double Primulas.—Having been a reader of your paper for some time past, I venture to ask a question. I have got several small glasshouses, and on a shelf in one I have about forty double Primulas, which have been in full bloom all the winter, and I am now anxious to propagate them. I have been told to fill the pots up with sandy soil. If this be correct, should I cut or sick them like Carnations, and shall I shade them? Please tell me what best to keep them in?—MUSCAT.

[Considerable difficulty is sometimes experienced in increasing the stock of this most useful winter and spring-flowering plant. As soon as the blooming is past remove the whole batch to a shady position in an intermediate-house, divert them of all their lower leaves, and fill in the vacant spaces at the top of the bells with new sweet Sphagnum, sifted loam, and silver-sand in equal proportions, raising the material somewhat above the pot in the form of a small mound, so that the bare portions of the old stocks are covered. This mulching is then kept continually moist by the daily use of the syringe, and so rapidly do the plants root into this medium that in a month's time the whole batch may be divided and potted off. Each crown or portion is separated with a sharp knife and potted, Moss and all. The plants are allowed to remain in the same house until established, after which they are placed in frames, and only a limited amount of air given for a time. Primulas, especially the double section, will stand, and even enjoy, more sun than many people suppose, while making their summer growth, their texture thereby becoming more consolidated and their flowering powers increased.]

Growing Amaryllis.—Please give cultural directions for growth of Amaryllis, when to pot, and after treatment? Also colour and shape of flower, and say if it will do out-of-doors? I do not mean Amaryllis Belladonna.—A.

[The different varieties of Amaryllis now in cultivation bear on the top of a sturdy stem (from 18 inches to 3 feet high) large, broadly funnel-shaped blossoms, which are just now at their best. In colour there is a considerable amount of variation, some having a light ground netted more or less with red, while all shades from light red to deep crimson are represented among them. They will not do out-of-doors. To succeed with them in pots they used the temperature of a warm greenhouse, and should, after flowering, be watered as before till the leaves begin to turn yellow, which will be about August. After this time water must be given, and when totally dormant they must be kept thoroughly dry. Throughout the latter part of the summer and in autumn they must be fully exposed to the sunshine in order to thoroughly ripen the bulbs. A shelf in the greenhouse or a frame fully exposed to the south is the best for them at that season. By the beginning of February a little water may be given, and this, of course, must be increased as the leaves and flower-stems develop. For potting, which, when

necessary, should be done before they start into growth, a suitable compost is two parts loam to one part each of leaf-mould, well decayed manure, and sand. In potting, shake the bulbs clear of the old soil. At one time it was considered necessary to repot every year, but it is not now so universally followed, and we have seen some good examples that had been for three years in the same pots.]

Forcing Anemones (Rockery).—Tubers of the Anemones require to be at least two years old before being of a size suitable for forcing, so that by sowing the seed at once you may, provided everything goes well, obtain the desired end in some three years to come. A better plan, we think, will be to purchase tubers as early as you can next autumn, and get them as large as possible. By potting these as soon as received (say September) flowers may be secured in February and March following. Four tubers will be ample in a 6-inch pot, and if the bulbs root quite freely you may even obtain a few winter flowers. Winter flowering is easily adjusted to the nature of all this tribe of plants. Heat, and excessive heat, minus the sun and its heat-giving influences, are just the things to ruin these beautiful flowers, and the only way to enjoy them in English gardens and in districts adjacent to large rivers is to plant them freely in a frame in the sunniest aspect possible, and keep all

given a suitable soil and position. In some gardens it is a rule to sow the first lot of seed early in March. This may do very well if large plants are needed and good accommodation can be given them, or if they are needed to be in bloom early in October. I fall, however, to see their value thus early. Really good plants can be grown for blooming during November onward by sowing towards the end of April. The chief thing is to keep the plants growing from the very first. I have often been impressed with this when looking over large trade nurseries where they are grown for seed. As a rule, I save any good variety for seed, and when the seed is ripe some time in July this is sown, and now (early in March) I have nice young blooming plants in 4-inch and 5-inch pots from this late sowing. Many fail to get the seed to germinate. This often arises from allowing the seed to float on the water at the first watering instead of making the soil moist first, then sowing the seed when the soil is set and covering it with fine, light sandy soil. If the soil is moist when the seed is sown and covered but little watering will be needed until it is up.—J. CROOK.

TREES AND SHRUBS.

A FINE IVY.

The illustration shows a good specimen of

Ivy "Clouded Gold" (*Hedera canariensis aureo-maculata*) over a doorway in a Norfolk garden. From a photograph sent by Mr. E. Banbury, 80, Cadogan Square, S.W.

frost away from the surface that will come through the soil in early November. Many would be quite satisfied if these Anemones would really force once quite well. Certainly they will not endure it twice in succession. If you still desire to try, pot early and introduce into warmth as soon as the pots are well filled with roots and ample foliage is in evidence.]

The Chinese Primula.—Few low-growing indoor plants are more useful or ornamental than Chinese Primulas when seen in good condition. These, like most soft-wooded plants, to have them at their best, should never receive a check. Often failure arises from sowing too early in very warm structures, then removing them into cold-pits or frames too early in the spring. Another evil is allowing the seedlings to remain crowded in seed-pans, or after they have been pricked out. When they have made large plants they are difficult to separate, and when the young, tender roots are destroyed the check is so severe that they seldom recover. When they are large enough to handle they should be pricked out into pans or boxes, and before they get too large it is best to lift them out of these with a nicot ball, placing them in 4-inch pots. Care should be taken in the watering after fresh potting. Often by careless watering at this stage the soil is made sour, and then the plants never take to the soil but have a yellow look and stunted growth. It is astonishing how fast these will grow when

Hedera canariensis aureo-maculata, known as "Clouded Gold." The garden in which it is growing (upon a wall looking west) is in west Norfolk. On the lower part of the wall the leaves are dark green, and the golden leaves all growing together at the top of the wall appear from a distance like a mass of yellow bloom, giving a most brilliant effect. The photograph was taken about 5 o'clock on an August afternoon with the sun on the creeper.

E. BANBURY.

NOTES AND REPLIES.

Climber for very hot, sheltered, south brick wall.—I wish to plant front of my house (as above), and am divided between a Vine and a Magnolia. The latter grows remarkably well in front border as trees—the Yulan and the common M. House too staked, much larger space to cover above than at the ground, owing to climbers already on it.—i.e., Roses, Clematis, Pyracantha, and Ampelopsis Vitis. For variety a Vine appeals to me. Kindly advise, and give names of most suitable and effective, time of planting, etc.—KERR.

[One of the best Vines for outdoor culture is the Sweetwater—that is, regarded from a fruiting standpoint—but if foliage effects alone are to be taken into consideration you may plant the out-leaved variety of the common Grape (*Ampelopsis*), or the huge-leaved Japanese *Vitis* *Coignetia*. A very pretty member of the Grape family is the *Vitis vinifera purpurea*, often called the Claret Vine. The leaves of this are in all stages tinged with purple, and in autumn before they drop they are very richly coloured,

This variety is, however, weaker in growth than the others previously mentioned. Whichever you decide on should be planted at once, and some good soil given the roots to make a start into. If you decide on a Magnolia, the Kilmont variety of the evergreen *M. grandiflora* will best suit your purpose. Planting should be done now and as recommended for the Vine.]

Treatment of dwarf Japanese trees.—Having purchased at a recent sale a Japanese dwarf Pine, 40 years old, I shall be very much obliged if you will inform me how I should treat it to keep it in good health? Do the roots require trimming to keep it from growing? I have no greenhouse, so keep it in the drawing-room, where it gets plenty of light.—BRAMMEL.

[Your Pine will only need the average attention given to plants grown in pots—that is, sufficient water to keep the soil in a moderate state of moisture, and an occasional syringing to remove the dust which is sure to accumulate on any plants kept entirely in the dwelling-house. No trimming of the roots is needed, as the plant has been gradually inured to this semi-moribund state by a process of semi-storvation, till its stunted condition has become chronic, and it is so permanently stunted that any attempt to induce it to grow freely would in all probability end in failure. If in process of time the soil becomes too much wasted add a little more.]

GARDEN PESTS AND FRIENDS.

NOTES AND REPLIES.

Fungus on Oak (F. W.).—The so-called fungus on Oak is really a Lichen (*Sclera pulmonacea*), sometimes known as the "lungs of the Oak." It is quite common, and is sometimes used instead of Iceland Moss as a nourishing food for sick persons. It is said that in Siberia it is used to impart a bitter taste to beer.—G. S. S.

Black Vine-weevil.—Kindly say what the enclosed grub is? I found over 100 in one pot.—ANON.

[The grubs you sent are those of the black Vine-weevil (*Otiorrhynchus sulcatus*), or a very closely allied species, the clay-coloured weevil (*O. picipes*). The grubs are so much alike that it is very difficult to tell them apart. These grubs are very injurious to the roots of many different kinds of plants—Cyclamens, Ferns, Primulas, Begonias, Sedums, Strawberries, etc. The only practical way of destroying them is to examine the roots of the plants and pick the grubs out, as insecticides strong enough to injure the grubs would kill the plants. The beetles, which feed on the foliage of Ferns, Vines, Peaches, Roses, and many other plants, are black and about 1/2 inch in length. They hide themselves under stones, rubbish, or some other shelter, coming out at night to feed, so that, though very common, many persons who know the grubs have never seen the weevils. Plants which are thought to be infested with them should be laid on their sides on a white cloth or sheet, and when it has been dark for about an hour, a bright light should be thrown suddenly upon them, this generally causing them to fall and lie perfectly motionless for a few minutes. If they do not fall, the plants should be given a good shake, and be carefully searched. Small bundles of dry Moss or hay should be placed on the soil near the stems of the plants or tied to them, so as to provide the weevils a handy shelter. These bundles should be searched every morning.—G. S. S.]

Titmice in gardens.—I am venturing to ask if you or your readers could tell me how far it is really proved that titmice do more good than harm in a garden? They have lately nearly stripped three Pear-trees of the blossoms, eating out the blossom and leaving only the husk. There is no apparent trace of insects in the buds left. On the other hand, the trees are old, and many of the Pears have dropped in previous years owing to a grub which gets through the Pear. It is said that titmice are insectivorous, and I they undoubtedly feed their young with grubs; on the other hand, in the autumn they eat *Sandwaver* seeds. How far is their devastation of fruit blossom due to a search for insects, and are they sufficiently successful to make their work worth while to the possessor of the fruit-tree?—M. BRUNSON.

[I think that there can be no doubt but that the titmice are very useful birds in gardens, and all ornithologists are of the same opinion. Many gardeners I know hold just the opposite opinion, but they are very apt to judge only by appearances, which are, it must be admitted, against them. It is quite a mistake to think that the birds that they attack are oused and would produce fruit if left unmolested.—G. S. S.]

The wood leopard-moth.—I will be much obliged if the accompanying grub is named in GARDENING ILLUSTRATED. It was found in the centre of a branch on a worn-out Apple-tree. It had burrowed along the centre of the

branch for 3 inches or 4 inches. The branch is about 2 1/2 inches in diameter.—A CONSTANT READER, *Old Chester*.

[The branch of your Apple-tree was infested by the caterpillar of the wood leopard-moth (*Zenzera tessuli*), one of our most elegant moths. The female measures 2 1/2 inches across the wings when they are fully opened, these being long and narrow, white, and almost transparent, with yellowish-brown veins. Between every two veins there is a row of rounded bluish-black spots, the head and thorax are covered with a thick white pile, the latter having three black spots on either side of the middle, the body is thickly covered with a thick black down, and each joint is fringed with white. The males are rather smaller than the females and have very deeply-toothed antennae. The presence of these caterpillars may generally be detected by small, sawdust-like particles which are thrown out by the caterpillar. If possible the branch should be cut off, but if it be undesirable to do so, the entrance to the hole should be slightly enlarged, and an attempt made with a pointed wire to catch the insect, or, if the wire be formed into a hook, to drag it out. If this fails, some cotton-wool or tow should be soaked in tar or paraffin-oil and pushed as far as possible into the gallery formed by the caterpillar, and the hole closed with a piece of well-kneaded clay, so as to assist in stifling the insect.—G. S. S.]

Grubs in a bed of Mint.—Will you kindly tell me what the enclosed grubs are, and, if left alone, would they turn to moths or what? I found them in a bed of Mint, which they have quite destroyed by eating the roots all away. I have picked hundreds out of a small bed. What is the best way to clear them from the garden? I have found others in different parts of the garden.—A READER.

[The insects you enclosed are the caterpillars of the common swift moth (*Hepialus lupulinus*), a common and very destructive pest to the roots of plants. I am afraid that there is nothing to be done but to turn them up out of the ground and destroy them, as insecticides cannot be made to reach them without seriously injuring the plants. By killing all you can find you will lessen the chance of an attack next year.—G. S. S.]

Fungus on Snowdrops.—I enclose specimens of Snowdrops which have been attacked by some sort of fungus or mildew, and shall be obliged if you will tell me what is the cause of it, if it is likely to spread, or if there is any remedy? The bulbs of the Snowdrops attacked have entirely disappeared.—D. O. B.

[Your Snowdrops are attacked by a fungus, *Sclerotinia galanthina*, which is nearly allied to the White Lily disease which has recently proved so destructive to that kind of Lily. I do not think that there is any cure for this disease. All the infested bulbs should be destroyed as soon as they show any signs of the disease, as it is very likely to spread.—G. S. S.]

VEGETABLES.

THE CULTURE OF ANGELOICA.

ANGELICA is the subject of special culture in the west of France, towards Niort and Châteaubriant. It is a biennial plant, exhaling a sweet odour, and having a warm, bitter, aromatic savour. It requires a good cool, deep substantial soil and a southern exposure. It needs frequent watering—"roots in the water, head in the sun," as they say. The seed is sown in nurseries in April, but the better way is to sow in September, when the seed has ripened, in a good exposure, for choice seeds sown in September do not always germinate in the same year. Seed sown in spring, on the other hand, germinates a month after or sooner. The seed is sown in lines a pinch at a time, and lightly covered over with sandy soil. Planting out takes place in the autumn, or in the spring following, when the roots are about the size of a little finger. They are planted 23 inches to 28 inches apart, then watered and covered with straw-manure. The only attention they receive during vegetation is hoeing and water in abundance until the autumn of the first or the spring of the second year. The ground is dug between and a good layer of dung or compost applied. The stalks are gathered in the spring of the second year or sometimes in the third year, when the umbels begin to lose their flowers. The plants are then between 3 feet and 4 feet in height. The stalks are cut down to the ground and bisected, leaving two shoots on the middle if the plants are to remain another

year. By preventing the plant from producing seed one can prolong its life for a year.

The seed is collected in August. The umbels are cut and put in the sun to dry, and when dried up they are separated, cleaned, and put in bags. But it is chiefly the stalks that are used in confectionery. When these are cut they are flattened out and cut into lengths of about 4 inches, and thrown into boiling water to whiten. When soft enough to yield to finger pressure they are taken out, the threads removed, and the pieces put into cold water to harden, after which they are taken out to drain. Treatment with boiling sugar follows in the process of transforming this vegetable into the sweetmilk which is so well known.

If it is intended to make use of the roots, these are pulled up in September, split into pieces, and kept dried in woodco boxes. Those of a year old are worth more than older ones. From the seeds of Angelica a pleasant liqueur is made, and in medicine its roots are more valuable than the other parts of the plant. Angelica is recommended for weak stomachs, and for gouty persons, and those who have weak digestions, also in the treatment of convalescents exhausted by long illness in the form of infusions of the roots and young, fresh stalks.

BLANCHED LEEKS.

THE note on these at page 1 of March 1st, from "A. D.," is a valuable one. I agree with all he says respecting their value when grown to about the size he names, and blanched as he describes. I prefer a dish of Leeks to most things during the first three months in the year. Owners of small gardens who may have grown them only in a green state should blanch them. Another recommendation is that a quantity of roots may be grown in a small space. Added to this, frost does not affect them when protected with soil to blanch them. Most lovers of good vegetables will agree that from the New Year onward the choice of vegetables is limited. Blanched Leeks have not been regarded with the favour they deserve. Since I have had the charge of a garden I have sown Leeks at the same time as the Spring Onions. When working out the rows for Onions I put one row of Leeks at each side of the quarter, sowing and treating just the same as the Onions. By the time the Onions are ripe the Leeks have attained to a good size. Early in the autumn, should they appear to have exhausted the soil, I give them a dressing of some stimulant, either in a dry or soluble form, according to the weather. Before the winter sets in these are protected, thus blanching them. This is easily done by removing the lower leaves and drawing a ridge of earth to them on both sides, as high as needed, leaving a portion of the green tops out of the soil. J. CROOK.

NOTES AND REPLIES.

Growing Winter Greens.—Can you say why the whole of my Winter Greens have not grown this year? I have pulled some up and find they are clubbed. Can you give any reason for it, or suggest a remedy? The earth is called "brick earth."—O. F.

[Where trouble in this direction has previously been experienced, preventive measures ought always to be taken. In many instances the roots of plants in the seed-beds will have commenced clubbing before they are large enough to put out. A free use of root and lime, forking it into the surface of the bed before sowing the seed, has a deterrent effect, and so also has sand soaked in petroleum, the surface of the bed being dressed with this every week or ten days. Before planting examine the underground portion of stem of each plant, and cleanly cut away every small excrescence or wart where found, following this up with the old-fashioned remedy of puddling the roots of all the plants. Form a puddle with clay, soot, lime, and water, a wineglassful of petroleum being also added with advantage, and drag the roots through this so as to thoroughly coat them and the lower portion of the stem with the puddle. Thus treated, they seem to feel the check of removal less than when not puddled, and are seldom interfered with by either maggots or wireworms afterwards. It is on stale, indifferently cultivated ground that grubs most often gain the ascendancy. Newly-slaked lime at the rate of 1 bushel per rod ought to be forked into the

surface of the previously well-manured ground, and after the plants have been put out, all being carefully fixed, clear water should be given for a time, or for the first week or so, afterwards giving liquid-manure frequently. Nitrate of soda, or that in mixture with superphosphate of lime, dissolved at the rate of 1 oz to a gallon of water, would be the best form of fertiliser for the purpose. Apply at first round the plants, but when the latter are growing strongly, draw mould up to the stems and pour the liquid-manure freely along the furrows. Petroleum is one of the best insecticides ever discovered, and in extreme cases of chomhing we would advise soaking and in it and mixing the latter freely with the soil in which the Cabbages are planted.]

Manuring poor ground (Myrrhis).—If the ground you found so terribly weedy has been trenched some 18 inches to 20 inches deep, and all the weed refuse was put into the bottom of each trench, the soil should be capable of sustaining a fair crop of strong-growing Potatoes, such as Up-to-Date. If you want to thoroughly clean the ground, nothing could possibly be better, as once the tops became strong they would smother weeds. It would be impossible for you to furnish anything like an adequate manuring at a cost of 10s. to 15s. per acre. Probably the best outlay of the latter sum would be in good fresh soot. Failing that, then get nitrate of soda, and give a thin sowing of that over the surface just before you sow or plant crops. Some of the crops named, especially Kales, would be too exhausting for poor soils. Some others would probably be stunted. If you planted all with Potatoes, as advised, kept them clean during the summer, lifted in the autumn, forked the ground over evenly and left it for the winter, it would be amply firm, then hoe deeply and clean off weeds before sowing Grass-seed in the ensuing April. When such treatment is adopted seedlings root deep, and get a strong grip of the soil, which helps to sustain them better than do mere surface waterings, which soon evaporate and leave the soil baked harder and drier than it was before. A sandy soil is not necessarily a very dry one—indeed, we find that it retains moisture better than do gravelly or clay soils, especially if the surface be kept well stirred. In the case of wind-swept gardens, such as yours is, it is well to plant frooly wind-breaks, such as hedges of Holly or Arbor-vitæ, or of anything which will check the force of the wind and allow plants in the intervening spaces to thrive. Even such temporary expedients as sowing Rape in narrow rows or drills, and allowing it to get 2 feet to 3 feet in height as a wind-break before cutting it down, are great help to plants. Something may be done by sucking in branches of Laurel or other ever-green shrubs, or of Fir, to form temporary protection to tender or seedling plants.

GARDEN WORK.

Conservatory.—Flowers are abundant now. Large pots planted with single Narcissus are very bright. Stella and Cynceure are very cheap and are light in appearance. Horsfieldi is a very dwarf variety, but is very effective in a mass. These require no forcing to flower now, merely planted a dozen or so in a good-sized pot and placed in a cold-frame till some progress has been made. It is not necessary to plunge in ashes or fire if the soil at the bottom is not rammed in very firm; the roots will go down and the bulbs remain in position. Standard scarlet or pink Thoros and Lahoums forced quietly bring a delightful whiff of spring in March. Now is the time to lay the foundation for a good display of climbing growth in spring and summer. Ipomea Leari is a gorgeous thing when in blossom. The roots are perennial, and when strong the growth spreads rapidly and the bluish-purple blossoms are of large size and freely produced. It is an old thing, but not often met with now. Granges and Camellias should have what pruning is required now. Plants in pots or tubs may not require much pruning, but when planted out in the border some attention is necessary to keep the outline perfect. This, also, is the best season for repotting. The plants will not thrive in a limestone soil; this is the characteristic of pretty well all hard-wooded plants. I have

seen Camellias and Acacias thrive well in good yellow loam; but, as a rule, a little leaf-mould, peat, and sand always improve it and are generally used. Roses which have been gently forced are lovely in bud now, and the flowers are more lasting than the early blossoms which have been pushed on in strong heat. Insects are very fond of the young shoots of Roses, and, if not destroyed, will cluster thickly about the buds. There are various ways of dealing with them. In the Rose-house use the vaporiser, but when the plants are few in number a sponge dipped in soapy water will clear them off or a little Tobacco-powder will settle them, and a syringing with clear water afterwards will make all comfortable again. Deal with all troubles of this nature promptly and they soon disappear. Do the watering in the morning. Give a little weak stimulant to all plants coming into flower.

Stove.—This is the season to repot Eucharises should it be necessary. Annual repotting is not always necessary or desirable, and it is well not to break up the mass of bulbs till the plants have reached a large size. When the mass of bulbs has reached a considerable size and seems inclined to burst the pot, then division must take place. These plants can be carried on for some time with liquid-manure, and the flowers are very freely produced under such conditions. The best compost is good loam two-thirds, as turfy as possible, and the other third equal parts very old cow-manure, charcoal (broken very small), and sharp sand. The pots must be well drained. Cuttings of the young shoots of Bouvardias will strike now in brisk bottom-heat kept close. Pot off the outtings as soon as rooted, and pinch from time to time. Some growers plant out and lift again in autumn; but my experience is in favour of growing them in pots. The Poinsettias are now for the most part resting. When the rest is over, give water, and syringe to get them to break. I like young cuttings, though short pieces of the ripe wood will root in bottom-heat. To get large heads of bracts the outtings should be struck early, though, of course, there is plenty of time yet. April and May are time enough to work up the main stock, though we never miss a cutting if we can help it. Epiphyllums may be grafted on the Pereskia or Cactus stocks now, or they will strike freely from outtings in porous compost. Grafted plants are the longest lived.

Orchard-house.—The trees will be in blossom even in a cold-house now, and careful attention to the ventilation will have much influence in the setting of the blossoms. Keep out cold winds. Damp the floors for an increase of temperature in bright weather. Ventilate early in the morning—not excessively, but admit air in small quantities, so as to avoid cold currents. Keep the roots healthily moist. As the growth increases, the demand for moisture will be greater, and if this demand is not promptly met something will soon go wrong, and the young fruits are the first to feel the change. Begin disbanding early, and then no great check need be given. Do not be in a hurry to pinch the young shoots, unless it is a case of grossness which is fast developing into a case of rothbery; then either remove the shoot altogether or stop it.

Figs under glass.—We have gathered ripe fruit of the White Marselles in May, and to do that the trees must be started early and a temperature about equal to that used for forcing Grapes kept up. When Figs are grown in pots they may be forced anywhere in a suitable temperature. We have forced them in a Pine stove standing on the back wall of the pit in which the Pines were plunged, and very good crops these trees in pots always produced. They were moved to another house to mature the second crop. In pot culture the feeding in the way of top-dressing and liquid-manure must be liberal, and when the plants have been in pots some time without a shift the roots may be pruned rather hard back and the pots reduced in size. The Fig under all conditions soon responds to warmth at the roots, and a leaf-hed will ensure good results. The leaf-hed in the vinery is not so common as it used to be, but I have seen very good early Figs gathered from pot-trees plunged in a bed of leaves in the early vinery. The disbanding and stopping of the young growths are important details. The stopping should be

done when five loaves have been made, and instead of pinching out the terminal bud, the best course is to raise the bud so as to hook further progress, but not altogether remove it. The object is to stop bleeding.

Window gardening.—Anything that requires larger pots may have attention now. Cuttings of Enchyses, Zonal Geraniums, Campanulas, and white and yellow Marguerites will strike now in the windows in a warm room. Geraniums will strike best without any covering, but other things will be best in a box covered with glass. Those who have a small frame on a hot-bed may do a lot of propagating now both from seeds and cuttings. Cuttings must have a little shade on bright days.

Outdoor garden.—There will be a good deal of work now in the propagating department. It is quite easy to have a very pretty garden without a single Geranium or taking the trouble to winter a single plant. Here is a list of plants which may be raised from seeds in February or March in the hot-bed or warm greenhouse, pricked off into boxes or pots, and when grown a little and hardened off be ready for planting in May: Petunias, splendid for dry, hot soils, Verbenas, Lobelias, Stocks, Asters, Dianthus (Indian Pink) in variety, Scabions in variety, Phlox Drommoldi, Mari-golds (African and French), Salpiglossis in variety, and Zinnias. Seedlings are often weakened in the seed pots by thick sowing and keeping them too long without transplanting. Petunias are among the brightest things in the garden in summer, and will thrive in the hottest, driest positions. Balsams are not much used in the beds, but they do much better planted in the garden than in pots in the conservatory. When used in beds or borders they should be planted 3 feet apart, and the ground between filled in with another colour of low growth. Verbenas, pegged down, will do, as would also the purple Heliotrope and white Stocks. Cuttings of almost everything will strike now in heat if kept close and shaded from the hot sunbline. Very pretty for grouping are the China Roses. Fellenberg makes a very bright mess, and is always in blossom from early spring till late in summer or autumn.

Fruit garden.—This is a good season for planting new Vineries where the borders are prepared and ready for the roots to work into. Many of our best Grape growers prefer borders altogether inside. When the question of feeding has been properly grasped inside borders are best, but roots in inside borders want a lot of nourishment, and the risk of neglect or want of judgment are greater than when the roots are partly inside and partly out. The best courses for the average man is to make 3 feet or so of border inside, and build the front wall on arches. Plant the Vines inside, and leave a free course for them to go outside when they like, and out they will go the first season. It is a mistake to make all the borders at once—the roots rosh through and are away out in the garden in three years. Keep the roots at home as long as possible, and with this object in view make the borders piecemeal, say about 3 foot at first and about 4 feet or 5 feet a year after. Sometimes the border making after the first year can be postponed so as to miss a year, by using rich top-dressings. It is a question of feeding more than extent of feeding ground. If heavy coverings are placed over wall-trees in blossom they should be taken off every morning when mild. Figs on walls should be pruned and restrained towards the end of the month. Take out an old branch here and there to give room to lay in young wood. A good dressing of lime will be useful under Gooseberries when the caterpillar exists.

Vegetable garden.—Those who grow prives Onions will now have their boxes of plants hardening off, and the ground made suitable for planting. The rows should be a foot apart, and the plants from 6 inches to 8 inches apart in the rows. Manure must be used freely in the preparation of the ground, and a top-dressing of short stuff, of which charred rubbish forms a part, will be beneficial. Later on a dressing of nitrate of soda will be useful. Plants raised early in this way get a good start of the Onion-fly. Those who have not sown their Tomatoes for planting outside should use no time now. Sow thinly in boxes, and grow from the start without check. Straw plants put out at the

end of May will render a good account of themselves. As regards variety, Holmes' Supreme and Laurenson's No. 3 are good croppers, but there are numbers of good varieties. The lets might be curtailed with advantage. Sow more Peas and Beans for succession. Antocrat and Duke of Albany are good Peas for sowing now. We find by sowing a second early with either of the above a succession is obtained. Sow a few seeds of Broccoli, Cabbage, and Kale for early planting. These things have frequently been sown too late when the season is dry. Run a string of matting round the earliest Cabbages to forward the heading. Sow and plant out Lettuces. Forward the Potato planting. Give them plenty of room—3 feet between the rows for large topped kinds is not too much.

E. HOBDAV.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

March 25th.—To clear the houses a little some of the autumn-struck Geraniums and other bedding plants have been removed to cold-frames. Coverings will be used at night. The Chrysanthemums have also been placed in cold-pits. All the early-struck plants are now in 5-inch pots. Precautions are taken against the advent of rust on the foliage, and the plants are closely watched. Sowed more Tomato seeds for outside; also more red Celery.

March 25th.—Planted out more Lettuces, and sowed seeds of White Cos and Continuity Cabbage Lettuces. A little more thinning has been given to the young shoots on Peaches, and the fruits thinned to about 6 inches apart on the averages. Some of the longest shoots have been tied in. Finished thinning Grapes in early house. This is the second time in going over the bunches, and only a little was required, and that little chiefly directed to relieve crowded parts of bunches and remove small berries.

March 26th.—Strawberries ripening are removed from warm-house to cooler quarters. The flavour is improved and the fruits are in a better condition for packing. Petunias and Verbenas raised in heat have been potted off or, in some instances, pricked off into boxes. They will be helped with a little warmth till established, and will then be removed to cooler house. Put in more cuttings of Lobelias in boxes. Sowed more hardy annuals, including things suitable for cutting. Potted a lot of *Lilium auratum* and *ancifolium*.

March 27th.—Planted out Gleditsia of various kinds in masses in the borders. Stirred the soil among bulbs in beds, which are growing freely. Manured and dug over a plot of land for Violets. The cuttings are rooted in boxes and will be ready to go out as soon as the ground has settled a little. Top-dressed Asparagus beds with nitrate of soda and raked the surface over. Top-dressed Cucumbers coming into bearing. The shoots are regularly pinched one leaf beyond fruit.

March 28th.—Disbudded Vines in late house. Orchard houses receive free ventilation on mild days. The stems of the trees are tapped with a padded stick about eleven o'clock in the forenoon, to distribute the pollen. Water is given when required, but no top-dressing or stimulant till the fruits are set and swelling. Dusted each over Peas to keep off sparrows. This has hitherto proved effectual, but if it fails other means will be adopted. Pruned various Roses. Teas will be left a little longer. Roses planted in autumn are now making roots.

March 29th.—Re-arranged conservatory to clear away hulks which have flowered, and fill in with other things coming on. Looked over climbers to thin and train growth. Earliest Pelargoniums are bursting into bloom. Azaleas also are very bright. Acacias going out of bloom are being pruned back. Put in a lot of Rose cuttings taken from forced plants under glass. We generally graft at this season a few Roses on Brier roots. Any healthy Brier roots as thick as a cedar pencil will do. The roots are grafted by what is known as whip-grafting, and then potted and plunged in bottom heat. Very few fail.

The Index to Volume XXIII is now ready and can be had from the Publisher, price 1d. post free, 34d.

BOOKS.

"THE BOOK OF THE APPLE."

THIS is the sixth volume of the series of "Handbooks on Practical Gardening" that is being issued under the general editorship of Mr. Harry Roberts, and is uniform both in size and appearance with its predecessors. For the information of those who have not possessed themselves of the volumes issued previous to the one now under review, it may be stated that Mr. Roberts deposes the writing of the practical portion of each volume to various authors, and to Mr. H. H. Thomas, the assistant editor of *The Garden*, has been entrusted the task of supplying that for "The Book of the Apple." This occupies some 80 pages, and the remainder is taken up with chapters by the editor, on "Apple Lore," "Apple Cookery," "The Evaporation of Apples," and "Cider-making," on which important matter Mr. Roberts has had the opinion and assistance of the best makers in the kingdom. The recipes given for cooking Apples are excellent, and the illustrations of the various and up-to-date machines and implements required for the manufacture of cider are extremely clear and good. Coming next to the more practical part of the treatise, we think that when compared with previous volumes of the series, this, the sixth, does not attain the same high standard that the others have done, viewed from a practical cultivator's standpoint, and although the information afforded will no doubt be of great service to amateurs and small cultivators, we fear that those engaged in the cultivation of the Apple, commercially and otherwise, will glean nothing that will be of assistance to them by a perusal of its contents. Apple culture has largely engrossed attention for several years past, and by the wide dissemination of information bearing on this subject by the gardening press, and by various works from the pens of eminently practical men, great strides have been made, and the old methods have given place to those of a more intelligent and rational character. Such being the case, the advent of a new work treating upon such a popular fruit as the Apple is eagerly scanned with a view to obtaining information bearing on some point or other on which they are not quite clear. Such will, we fear, be disappointed, but amateurs and others who wish to grow Apples on a comparatively small scale for private consumption will find much that will be helpful to them. There are several little matters on which Mr. Thomas has not touched, such, for instance, as the protection of the stems of "elandards" from attacks of rabbits and hares; the lifting and transplanting of the trees in lieu of root-pruning; the importance of winter-dressing the trees for all pests with the caustic alkali solution mentioned by him as a remedy for American-lyght only; and the spraying of trees before they blossom and immediately after the fruit is set with Paris-green, or Winter Moth Specific, as an antidote for the caterpillar of the winter and other moth. The chapter on storage is very good, and the list of varieties given and recommended can also be commended, but surely a mistake has been made in stating that Golden Noble does not keep well? A short chapter on budding, grafting, and training completes the portion of the work for which Mr. Thomas is responsible.

LAW AND CUSTOM.

The right to light.—A bought a house with ground around. The house stands about 4 feet from the boundary wall owned by B, and there is also a greenhouse about the same distance from the boundary wall. B has now raised the wall to the height of A's house, thereby obstructing the light and the heat of the sun. Can he be compelled to remove the addition to the wall?—*Tox*.

[It is not stated whether the obstruction complained of is in respect of the house or of the greenhouse, but as a greenhouse was held in *Clifford v. Holt* (1899) to be a building within the meaning of the term "building" in section 3 of the Prescription Act, 1832, the matter is immaterial. The right to the unobstructed flow of light and air is gained by twenty years' enjoyment, or by express or implied grant. If the house and greenhouse have been erected more than twenty years, the right to light is pretty certainly been gained, but you do not

say how long either has been built, nor whether there are any windows in the house overlooking this wall. If there be, there can be no doubt that the heightening of the wall has seriously interfered with the access of light to those windows, and an injunction may be obtained to restrain B from obstructing the light, and this practically means that in addition to the wall would have to come down. A will be well advised to consult a solicitor on the matter, as if he has gained the right to light he will need a solicitor's assistance to enforce his remedy, and even if the buildings have not been erected twenty years there may be circumstances from which a grant may be implied.—*K. C. T.*]

A tenant's claim for compensation.—A took 20 acres of waste land on a yearly tenancy under an agreement to leave the land in the same state as he found it. He sunk a coal-pit in the field. He died subsequently, and his trustees gave up the field. I have taken the land on the understanding that it is made good. The trustees have filled up the pit and have spread the remaining refuse over two acres of good soil, and have put a thin covering of soil over so thin that in rain or snow old bricks, stones, and stumps are on the surface. I cannot expect any crop unless more soil be placed on the surface; but the trustees say they will do no more to the land. I have already carted 100 loads on, but more is still required. Can I claim any recompense?—*D. B. AND J. W.*

[It depends upon the bargain made with the landlord whether you can enforce any claim or not. If you agreed to give a certain rent on the condition that the land was put into proper order, you may claim from the landlord damages for his breach of contract with you, but unless there was such a condition and you can prove its existence, you can enforce no compensation. It may be as you say, that, as between the trustees and the landlord, the trustees were bound to make the land good, but there was no obligation on the trustees to do this for you. You have nothing to do with the trustees and they have nothing to do with you. The landlord may, if he thinks fit, recover compensation from the trustees, but you can do nothing against them. Your only course is to complain to your landlord, and ask him to claim damages from the trustees. Of course, if the landlord contracted with you to make the land good, you may recover damages from him.—*K. C. T.*]

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.

ANNUAL MEETING.

The annual meeting was held under the presidency of Mr. Herbert J. Cuthbush, at the Caledonian Hotel, Adelphi-terrace, Strand, W.C., on Monday, March 10th. The report for the past year was unanimously adopted, and it was decided to print 3,000 copies of same. Eighty-three new members have been elected during the year, and over £300 has been distributed in sick pay. The secretary's salary, printing, postage, and auditor's fees, etc., amount to £168. The treasurer has invested £1,800 during the year, the total invested funds now being £19,000.

Mr. Cuthbush, in the course of his remarks, said he hoped the membership by the end of the year would be 1,000, and that the invested funds would be £20,000.

The retiring members of the committee were again elected, also secretary, trustees, and treasurer.

For reports and rules readers should write to the secretary, Mr. W. Collins, 9, Martindale road, Balham, S.W.

—The monthly committee meeting of this Society was held at the Caledonian Hotel on Monday evening last. Mr. C. H. Curtis in the chair. Seven new members were elected and two others nominated. Ten members were reported on the sick fund; the amount of money paid out for the month being £33 12s. The sum of 30s. was granted to a sick member from the convalescent fund. The decision of the committee at the last meeting was upheld in the case of a member who wished to be re-instated. The death of two members was reported, and cheques were drawn for the amounts standing to their credit in the ledger, being £32 1s. 1d. and £23 7s. 1d. respectively. A hearty vote of thanks was given the chairman and vice-chairman for their services during the past year, and at a subsequent meeting they were unanimously re-elected for the ensuing year.

BEES.

SEASONABLE WORK IN THE APIARY.

The Crocus and the various kinds of Willow yield large quantities of pollen in the early spring, which is eagerly gathered by Bees for the feeding of the young, being mixed with honey and water for that purpose. When more is gathered than is required for present use it is stored in worker cells and sealed over with wax. The Bee foraging in the flowers becomes powdered with pollen, this it brushes from its body with its front legs, which are provided with brushes for this purpose, and collects and kneads it up into little pellets, which are transferred to the hollows of the hind legs formed for its reception and transportation. When many bees are seen carrying into a hive large quantities of pollen-pellets of various tints it is a pretty sure sign of prosperity and increase of population. When natural pollen cannot be obtained by the Bees in sufficient quantity it is the custom with some Bee-keepers to supply them with Pea-meal, placing it in shallow boxes, in a warm and sunny spot near the apiary, a few shavings being mixed with the meal to provide a foot-hold for the Bees. This artificial pollen is found to answer in brood-rearing, and is collected by the Bees as freely as natural pollen. Water is also carried into the hive at this season, and here again much help can be afforded by placing near the hives shallow pans of water with small sticks of wood floating upon the surface. This will often save the Bees the necessity of travelling long distances in search of water, which is so necessary in brood rearing. Indeed, so eager are the Bees to collect water in the early spring that many venture out for this purpose even in unpropitious weather, and never regain the hive. A little water provided near at hand obviates all this. Hives that were properly provisioned in the autumn will not require feeding at present. Where, however, feeding is found to be necessary to prevent starvation, the food should be applied in mild weather only, and in the evening, and only as much given as will be taken in a few hours, that the Bees may have become quiet before the morning. If fed during the day the excitement caused by the supply of food will induce them to fly abroad in search of a natural supply, and many may never return. Candy and Barley-sugar are both good for winter and early spring feeding; or a good feeding syrup may be made as follows: To 3 lb. of boiling water gradually add 10 lb. of granulated sugar, keeping it stirred with a wooden spoon till all the sugar is dissolved, then add half a teaspoonful of water in which has been dissolved a teaspoon, level full, of tartaric acid, when, after stirring a moment, remove from the fire. This, when cool, will be found of the consistency of ripe honey. It should be supplied (just warm) in a feeder placed on the top of the hive, the whole being covered with some heat-retaining material. The tartaric acid prevents the syrup becoming candied. Another very excellent food can be made by mixing liquid honey and finely-powdered leaf-sugar together to the consistency of putty. This can be laid upon the tops of the frames in the form of a cake, and is readily taken by the Bees. By feeding thus no disturbance is caused to the colonies.

Many stocks that were fed up heavily in autumn have even now a superabundance of stores, and feeding in cases of this kind is worse than useless, because any food supplied now will be used for daily consumption, while the sealed stores will be left occupying, in some cases, thousands of cells which should be usefully employed in the rearing of young Bees. If a frame of worker-comb filled with sealed honey be uncapped and set in the centre of a strong stock, it will be found that in about a week the food has been removed by the Bees from the cells, while thousands of eggs and larvae have taken its place. In examining hives in the spring, old colonies will sometimes be found overstocked with last season's pollen, while younger hives are short of it. A very advantageous interchange of combs may be made when this condition of things is observed. Strong stocks, with plenty of stores, begin breeding often as early as the month of January, and prosperous colonies should soon be in possession of large quantities of brood.

CORRESPONDENCE.

Questions.—Queries and answers are invited in *Gardening Illustrated*. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF GARDENING, 27, Southampton-street, Covent Garden, London. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent each should be on a separate piece of paper, and not more than three queries should be sent at a time. Correspondents should bear in mind that, as *Gardening Illustrated* is sent to press some time in advance of date, queries cannot always be replied to in the issue immediately following the receipt of their communication. We do not reply to queries by post.

Naming fruit.—Readers who desire our help in naming fruit should bear in mind that several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. The differences between varieties of fruits are, in many cases, so trifling that it is necessary that three specimens of each kind should be sent. We can undertake to name only four varieties at a time, and these only when the above directions are observed.

PLANTS AND FLOWERS.

Geniatae (T. Jaeger).—These should be cut back after flowering, and after they have begun to grow repeat them, using loam, leaf soil, a little manure, and sand. Keep them close and shaded for a time until they have started to root freely. Gradually harden off and stand in the open air during the summer, being careful as to watering, as, if this is neglected, the plants will lose all their foliage.

Sweet Peas (Beginner).—All the Pea family prefer a rather stiff soil to root into, and never do well in loose soil. You will need exercise discretion in this, however. Light sandy soils may receive a good deal of firming with limonite. Heavy soils may be firming down with the back of the fork if dry and in good condition at the time; while light soils may be made firm by treading before and after planting.

Yucca filamentosa (Kent).—As *Yucca filamentosa* is hardy you may leave your plant, with its attendant suckers, alone, as it will thereby form an effective mass or clump. If the leaves are still tied up they should be loosened at once. One caution to be observed in the case of plants that have been tied up in this manner is that the young leaves in the centre are, when first exposed, very tender, hence they should be protected from sharp frosts till they have recovered their normal condition.

Removing stones from the soil (S. R.).—Unless the stones are of a size to be later removed by the proper working of the soil it is undoubtedly a mistake to remove them, so they play a valuable part in the economy of nature, keeping the soil open and properly drained, while, on dry soils, stones scattered on the surface prevent so rapid an evaporation as would otherwise be the case, and thereby assist vegetation. The practice of removing every stone is likely to encourage the Mossy growth, as the presence of Moss indicates a more or less stagnant state of the soil, and this stagnation is, of course, made worse by picking out every stone.

Daffodils in fibre (Beginner).—If the bulbs are planted wholly in fibre, by which we presume you mean Cocoon-fibre refuse, it is on woeless signs of failure we are assured. There is absolutely nothing to be gained in planting or rooting in this material, and the water would pass away without doing the least good. You cannot make things much worse now if you lift the bulbs and replant in good garden soil. Doubtless the roots have perished in the fibre, and if so, no new bulb will be formed this year, and no good growth will appear next year. In two years the bulbs may pull through somewhat. There is no better kind for the gardener than Narcissus Horsfieldi, and it is perfectly hardy and increases abundantly if left in the soil from year to year. Dig the ground deeply before replanting the roots, and employ some sand about the bulbs.

Wallflowers in a cool-house (Rockery).—Sow the seeds at once and grow the plants as freely as possible all the season. The seedlings may be planted or stopped to promote a more bushy growth, but this should not be encouraged after July, and at each time only the most erect point or tip should be removed. The better plan would be to remove the point when the seedlings were a few inches high, and again when a inches of growth have been made. By potting quite firmly in September you would obtain all that was possible in the time, but Wallflowers do not flower much in midwinter unless the spikes are already formed in late autumn. The best kind we know for winter flowering is the old double yellow, and this does best when kept in rather small pots. This variety cannot be raised from seeds, but from cuttings.

Soil for potting (S. R.).—The worst possible soil for potting is that which has been passed through a sieve with a 1/2-inch mesh; indeed, the tougher portion which does not pass through would, in the case of many plants, be by far the best to use. The only cases in which fine sifted soil is the best, are for sowing minute seeds and for many cuttings. For potting young and delicate subjects into small pots it is a great convenience to run the soil through a sieve, but, in that case, one with a 1/2-inch mesh is preferable. For potting and repotting in general, by all means use rich fibrous old turf as your basis, with different mixtures according to the requirements of the plants. A good compost for most subjects may be formed of two-thirds loam to one-third well-decayed leaf-mould, or a mixture of manure and leaf-mould, with a free sprinkling of sand. As loams vary a good deal in consistency, some of the heaviest are all the better if mixed with an equal amount of leaf-mould. Failing this last, peat may be used instead. Of course, there are many plants that this mixture will not suit—Azaleas, for instance, which need good fibrous peat, broken up by the hand, and sufficient drainage to be readily seen when mixed.

Thrip on Azaleas (Southdown).—The Azaleas-leaves you send are badly attacked by thrips. Syringing the plants with paraffin emulsion, Quassia extract, and soft-soap or Tobacco-water. A cheap insecticide for the destruction of this pest, also green and black-fly, is as follows: Tie up a peck of root in a canvas bag and place it in a hogshead of soft water. Stir the bag of root about daily for a week, and then add about 3 lb. of fresh sea-salt lime. When the lime has clarified the mixture it may be used for syringing, diluting it if necessary. Try it on one or two plants first. This is an excellent syringing mixture, not only freeing the plants from insects, but also giving health and vigour to them.

Ferns under greenhouse atags (Leck).—You will find a large number of the free-growing kinds useful as—e.g., *Nephridium melle*, *Cyrtanulum falcatum*, *Pteris of the linear type*, and the well-known British *Maidenhair*, *Adiantum capillus-Veneris* is usually one of the best. If not too dark and too much drip overhead, *Pteris aquatica* will do well and spread freely. *Doodia aspera*, *Pteris tremula*, together with the ordinary *Maidenhair*, *Davallia canariensis*, and *Woodwardia radicans*, would also be useful, and, with some of the Selaginellae, make good variety. Any rough, peaty mixture, with ordinary loamy soil added, will do, or even the old potting soil from Ferns, if a supply is at hand.

Pinching or stopping plants (Rockery).—Generally this is no rule for this, and, with such things as *Phlox Drummondii*, nothing to be gained. Wallflowers of a known rather leggy kind may be pinched to make more bushy plants, otherwise, if given plenty of room to develop, they branch out quite freely naturally. In *Falargonia*, all depends upon circumstances—e.g., winter flowering kinds are pinched twice or more, and all blooms removed so that the plant may be strengthened and devote all its energies to making good flowering branches for the time to come; and any pinching or stopping should be on these or similar lines. To stop plants of the annual or biennial class is only to delay a flowering which may be better secured by a later or even a successional sowing of seed.

Pot-Roses in a room (Beginner).—The shrivelling up of the bottom leaves is probably owing to too much moisture at the roots. It is just possible you have given the plants rather a large pinch of the Fertiliser. It is a mistake to use artificial manures upon room-grown plants. The Rose is not a good subject for room culture, its foliage requiring a rather moist atmosphere, and under plenty of sunlight can be given, which enables the plant to utilise the manure, this should be avoided until bloom-buds are visible. We should advise you to water more sparingly at the root, but the leaves will be the better for a daily sponging. To prevent the soil drying so quickly, a good plan would be to obtain a box containing some Cocoa-nut-fibre refuse and plunge the plants into the latter, keeping the fibre moistened now and then.

Stopping Chrysanthemums (Dulley).—Calvat's Sen, stop middle of April, crown bud; Lady Roberts, a Colonial introduction, which you had better try in one or two ways, stop early April; Dolly Glide, end of March, second crown; Miss Elsie Polton, stop middle of April, crown-bud; Canary Bird, stop early April, second crown; Heroine, stop early March, second crown; Mrs. J. Thornycroft, stop middle of March, first crown; Major Plumb, stop middle of March and secure first crown; Mile. M. Lager, stop middle of March and secure first crown. Nina and Lily are best treated as from the decorative point. All those grown for this work may be stopped twice if bushes are required, securing the buds any time after August 15. Not a few of the most shapely flowers are the result of one stopping and securing second crown buds.

Fuchsia for sheltered corner (S. H.).—If you have room at the start you should try the following three kinds, which represent the hardest types of this family: cocoon, globe, and the well-known *Hiccup*, which is the most in vogue. The others are very beautiful, but, and the first, perhaps the most hardy. It is not often the plants are killed outright. Even though the tops are cut down the roots break up again. If your soil is badly drained, dig out a couple of feet and put in bricks for drainage to the extent of 9 inches. Then lighten the soil with sand and grit and leaf-soil, and plant early in May. For winter protection Cocoon-fibre or coal-ashes is good, or a barrowload of dry Oak or Beech-leaves. A good protection is gained by planting right up to the wall, but this should not be so useful in your case.

Planting flower-beds (Scraper).—Your proposal to have in your flower-beds this season only red, white, and blue—the National colours—may give you pleasure, but this season it may become monotonous and hardly artistic. However, do not in any case use only three kinds of plants. You can have blue in *Lobelia*, Tufted Pansy True Blue, *Ageratum Perle Blue*, blue *Verbena* from seed, and blue *Salvia*, either raised from seed or from cuttings. Reds can be had in *Geraniums*, tuberous and fibrous-rooted *Beconias*, usually very persistent to bloom, and *Verbena*. Of whites, *Begonias*, silvery variegated *Geraniums*, white *Petunias*, white Tufted Pansies, Sweet Alyssum, *Dactylis glomerata variegata*, and *Cerastium tomentosum*. The last two are white leaved plants. Naturally quite dwarf things should go in the taller beds, but none of the things should be tall, as, if so, there will be no good effect.

Roses Marechal Niel and Crimson Rambler (Alden).—The growth of 7 feet is a moderate length for the growth of Marechal Niel to attain, and, unless they are very weak, you had better leave them as they are. The growths may be bent horizontally on the roof if you are unable to take them up perpendicularly. If some stout iron wires are put into the rafters, about a foot from the glass, the growths could be secured to these. The new shoots now forming will bear the blossom later on, so that if you desire to shorten the growths a little you must lose out time in so doing; but we should say this is not necessary, excepting, perhaps, 5 inches or 8 inches of the extreme ends. With this grand Rose, all the plants we have had them with grow the July 14 feet in length. If such plants are liberally fed they yield fine yellow blossoms either grown in pots or planted out in a well-prepared border under glass. The Crimson Rambler, having only one long shoot, should be left unpruned. If it is planted in some good soil it will quickly make up for its present lack of height.

VEGETABLES.

NOTES ON PEAS.

I HEAR that seed of many varieties of Peas is likely to be scarce this season, owing to the drought last summer, but as this will necessitate thin sowing it may, after all, be a blessing in disguise, as thick sowing, which is a great evil, is still very common, especially amongst amateurs. Nothing very startling in the way of early Peas has been introduced of late, but no fault can be found with existing varieties, either as regards cropping or quality. The dwarf forcing sorts are still best represented by American Wonder, William Hurst, and Carter's Lightning, which, if sown in a sunny pit or deep frame in January, will afford useful gatherings a month before the earliest outdoor sowings. Chelsea Gem is probably the most popular of early Peas. It is hardy and prolific, and, being a wrinkled Marrow, is generally preferred to the round-seeded varieties. Not unfrequently early Peas are grown on the same ground many years in succession, with the result that it becomes Pea-sick and unable to afford the crop sufficient nourishment. Where growing them on the same ground annually is unavoidable, the top spit should be removed every two years and replaced with good loamy soil, in addition to which a liberal dressing of rich but well-decomposed manure should be given, and the ground bastard trenched. That dwarf, hardy, free-cropping Pea Early Sunrise is, I believe, still grown for market, especially in the midlands. It is scarcely good enough in flavour for garden culture, but for field culture, and producing early and heavy crops, few sorts surpass it. Wordsley Wonder is a grand second early variety, producing its long, well-filled pods in great profusion. If mulched and well watered it will continue bearing for some time. The quality is excellent, and it is a first-rate variety for market. Stratagem has stood the test of time, and is still a general favourite. Few varieties possess such good all-round qualities. The pods, which are fresh and continuously produced, are long, handsome, and covered with a delicate bloom, the Peas being of a dark-green colour and deliciously flavoured. Amsteurs cannot grow a better variety. Parrot's Prolific Marrow, a new Pea of great excellence, will doubtless become a general favourite. It belongs to the Veitch's Perfection type, but if sown at the same time as that standard variety, it is ready for gathering three weeks sooner, and is equal to it in quality. Its average height is 2½ feet. Sharp's Queen should be grown by everyone, as it possesses every good quality that may be expected in a Pea. Its height is 3 feet, and the long and handsome dark-green pods are filled with Peas of delicious flavour. It is a great favourite in Lincolnshire and Notts, and is largely grown by cottagers. It does well in light soil. Stourbridge Marrow is a most profitable variety, growing to a height of 4 feet, and bearing its large, well-coloured pods continuously, and

light shallow soil. Prodigy is another grand sort, similar in height and general character to Stourbridge Marrow. I grew it for years, and was highly pleased with it. Filbasket is a superb sort for small gardens, being a prodigious cropper and of excellent quality. I used to grow it in shallow trenches, and mulch and water it well, and it did splendidly. Lye's Favourite, a 3½-foot Pea, is one of the best and most profitable varieties in cultivation. In some parts of Northamptonshire it is grown almost exclusively. Autocrat, a splendid dry weather Pea, is indispensable. It is a vigorous grower, and unrequiring for light warm soils, as it resists mildew well, and if well watered yields for a long time. It is a good substitute for Ne Plus Ultra where the soil is too light for the latter. Where the soil is deep and rich enough, and tall stakes are procurable, Ne Plus Ultra and British Queen should always be grown for late supplies. In deep loamy soil I have known them grow 7 feet high and crop prodigiously from base to summit. Walker's Perpetual Bearer is still one of the best medium-height late sorts, and a capital mildew resister. It is invaluable for retentive soils and low-lying situations, and is a great and continuous cropper. I should have mentioned that there is an inferior variety of Stratagem, with light green pods, in commerce, and that therefore it is necessary to procure the seed from a reliable firm.

KEEPING ONIONS.

READERS of this paper who do not see the "Journal of the Royal Horticultural Society" can hardly be aware of the fact that three years ago a trial of autumn-sown Onions was made at Chiswick, and it was so inclusive that it comprised no less than forty-eight so-called varieties. Two primary objects were in view in conducting the trial. The first was to see how far Onions of the Spanish and Globe types, ordinarily sown in the spring, stood the winter as compared with the Rocca and Tripoli varieties, usually sown in the autumn; and the second to test keeping properties. A third test, not anticipated, but which occurred during the progress of the trial, was the difference between transplanted and non-transplanted Onions. So far as relates to the latter test, ample evidence was furnished to show that not only did the bulbs of transplanted Onions keep longer, but also that they were finer and of superior form. That has been freely substantiated generally; but in relation to keeping properties of varieties generally, the fact that the very worst keepers are the soft Tripolis and Rocca varieties so generally sown in the autumn, was specially established. Not a variety of these types was sound by the end of the year, and very many were useless even earlier. The white varieties, such as the Leviathan and Lisbon, always decay very speedily. On the other hand, many varieties, such as Bedfordshire Champion, Fordo Long Keeping, Magnum Bonum, The Wroton, and others, kept sound until June, and even then others were sound up to the middle or end of May, some even keeping as long and as sound as did the bulbs from spring sowings of the previous year. With respect to the general

hardiness of plants of varieties little difference was seen. Fogs, as usual, thinned the plants very much, but one variety was hardly any more hardy than the other. The trial has thoroughly demonstrated the fact that of all Onion varieties for autumn sowing the Tripolis and the Rocca are the most worthless.

A. D.

BURNT CLAY IN THE GARDEN.

THE value of burnt-bake, charcoal, wood-ashes, and the like is generally recognised in the garden, and is recommended when putting plants or in the construction of fruit or plant borders under glass. I have known the value of this material for years, but, as so often happens, the opportunity for obtaining it does not occur so often as one could wish. During the past winter a deep excavation into clay land provided the means for burning some for the garden and greenhouse. In the potting soil now come of this material has been mixed, and the growth shows the value of its presence in the soil. Chrysanthemums revel in it, as do also Carnations and many other plants. A heap of this ballast is looked upon as a valuable adjunct to the potting materials, and every soil prescription now contains a proportion of it. In the garden it is common knowledge what a direct influence ashes has on the working of heavy land or that which is of a close or pasty nature. It is well known, too, how attractive coal-ashes is to some plants, and how freely roots will ramify through and among them, particularly those of pot plants standing on an ash-bed. The manurial value of ashes is not of much importance, nor is there much food in them, or plants would assume a more vigorous character when given an unlimited root-run. Gypsum is said to be a product found in coal-ashes, which in a purer form is employed in some artificial manures. Burnt clay sets on the soil like charcoal.

A plot of ground measuring from 10 perches to 12 perches was cleared last autumn of Raspberries, these being removed to a fresh site. During the several years' tenure of the land by the Raspberry crop the soil became much trodden and compact, simply because the nature of the crop did not allow much surface cultivation. After this land had been deeply dug and left roughly exposed, a good dressing of the burnt clay was spread on the surface and left for the frost, rain, and air to pulverise it. After severe frost the surface was again moved with forks, and now the advantages both of the ballast and the frosty weather is clearly in evidence. Potatoes will occupy the ground in question as a preparatory crop for Strawberries, and I hope that the labour that has been already spent will give a good return in at least two prospective crops.

To those having no experience in burning clay, it may seem a great and perhaps a laborious undertaking. If the clay can be had locally for digging, or, as in my case, it can be brought easily from a distance, the burning is not a great item. If a fire be kindled with wood and coal, or, what is equally suited, house-embers, the clay lumps may be arranged in a cone-shaped heap, enclosing the fire, and in the course of feeding the fire put on alternate layers of

clanders and clay. Once well alight it is remarkable how freely the clay burns, and how soon one may get a heap of valuable material, from a garden point of view. An effort should be made to keep the fire from burning through, but not to overload it by an excessive charge, which will exclude the necessary air, while a sufficiency will aid slow combustion, rendering the material more fertile. With favourable weather and the clay in a dry state, the fire will burn freely and need attention twice or three times a day. Gardens having heavy clay subsoils may be made much more productive if some of the under spit is brought up, burnt, and spread over the surface. W. S.

SOWING THICKLY.

On the packets of such as Carrots and Beetroot it is often advised that the seed be sown thickly, but in my opinion it is out of place, as many sow much too thickly, with the result that crops that would yield a good return are so weakened that it is impossible for them to stand against disease and drought. I am aware there is another side to the question, namely, entire failure of crop by thin sowing of certain seeds which are of doubtful germination. Not only with vegetables, but with flowers also thick sowing is far too common. I have frequently seen hardy plants and half-hardy annuals sown so thickly that the season was shortened and the flowers weak of little value. Present day gardeners pride themselves upon improved culture in most departments of horticulture, and rightly so, but we have room for improvement in the matter of both thick sowing and planting also. The great fault of thick sowing is that we do not thin sufficiently. We crowd Potatoes far too much, and many who give a fair distance between the rows have far too many sets in the row. Peas are strangled in their fight upward, many of the tall growers and Marrow varieties losing all their bottom leaves and becoming an early prey to mildew. The Sweet Peas, given plenty of room and rich soil, are very useful; whereas if crowded the flowers are small and the season soon over. Very often as many seeds are sown in a drill as would plant six or more. The plant, given more space, branches out and, being stronger, has more root-hold and is better in every way. Take Asparagus. This of late years has been given more room, with the result that we have much better grass.

I have only named a few things we do not treat well, but my remarks apply with equal force to most vegetables and other plants. The plants when once they are weakened in the beds rarely regain strength if left too long before they are thinned. In the case of the Brassicas, how often do we sow six ounces or half an ounce in the space that would not allow a quarter of the plants to grow. The same remarks apply to salads. Lettuces are often sown so thickly that they are quite useless, being so drawn. I find the spring end summer sowings suffer most. The autumn plants, not being so vigorous, are less liable to suffer, and it is much better to make several sowings, as then there are a succession of plants and good material. W. E. R.

NOTES AND REPLIES.

Autumn-sown Onions.—If these were thickly sown in a small bed or plot with the idea of planting them out in spring, this must be done soon, especially as the plants have had to check to growth throughout the winter and have already got big. They will need careful lifting from the seed-bed, as the roots are brittle, and any great loss of roots or check of any kind will predispose the plants to rotting. In planting, the roots only should be buried, as deep planting leads to badly-shaped bulbs. A good plan with these Onions is to sow a fairly large bed in autumn, letting the majority of the seedlings mature where sown, and only transplanting the thinnings at this time of the year.

Old versus young Rhubarb roots for forcing.—Everyone with a garden may have forced Rhubarb. Seeing there are so many ways of forcing the roots, the difficulty with many is to obtain a continued supply of roots for forcing. This is best done by raising a young stock frequently, as these young roots are far better for this purpose than old

out roots. Good strong roots may be had from three to four years, according to the soil and treatment. My way is to raise a young stock every other year from seed. Some may say Rhubarb does not come quite true from seed. I find, by planting out thickly, I can see any poor or worthless plants the first autumn, when I remove them, thus causing no inconvenience. Seed can readily be obtained from any seed house, or you may save your own.—J. CROOK.

Lime from acetylene gas.—I have seen no reply to a query asked some time ago as to the garden use for the lime refuse from acetylene gas. I have used acetylene gas here with entirely successful results for two years. For eighteen months the refuse remained in a pit where it is thrown daily, the farmer being afraid to use it, and my gardener the same. One day the maker of the generator arrived and inquired why we did not use such a useful article in the garden, the reply being that we were ignorant of its value. We were told to do as follows, with what result so far I have not had time to see. The lime has been well mixed with a heap of sods and refuse-soil, which is to be thoroughly turned three times during the year. Next autumn it is to be wheeled on the ground and presently dug in. It is said to be extremely useful where land is infested with wire-worm.—G. M. SANDERS, Lincoln.

Oraneton's Excelior Onion.—From a famous Hampshire grower of Onions, Mr. N. Kueller, of Malshanger, has come to me half-a-dozen of Cranston's Excelior Onion, quite a superb sample, sent to show how well the bulbs of this fine globe-shaped variety keep. That a good deal of this keeping property is due to the splendid maturation the bulbs have had there can be no doubt, but, all the same, good keeping properties are inherent to varieties, and globe-shaped Onions usually keep longer than flatter ones do. The bulbs sent, which were some 2 lb. each in weight, have more pointed bases than have ordinary good-formed bulbs of Ailsa Craig. They are handsome, hard, glossy, and clean. One of the lot that I had cooked was as mild as could be desired, and deliciously soft and flavoured. These large Onions make, so served, really delicious food, and are singularly nutritive. The stock is a first-rate one, and comes in seed form from a Hereford firm, who, it is evident, take great pains to have it pure.—A. D.

Treatment of Tomato-plants.—Will you kindly inform me whether young Tomato-plants should have the soil pressed firmly round their roots, or not, when transplanted into their place for fruiting—viz., a long bed in greenhouse? And is it necessary to repot them two or three times? I have grown mine in pans, and they are now a foot high, and I am thinking of now transplanting them direct to the greenhouse-bed to remain there.—R. N.

[It is somewhat distressing to learn that Tomato plants yet in pans are 12 inches high, as they must of necessity be very leggy and weak. It is a pity you had not got them singly into small pots when they were but 4 inches in height and kept them near the glass, as they would now have been sturdy, well-leaved plants, fit to turn out into the border where you wish to grow them. If you plant out these long, drawn ones, do so in such a way that you can bury the stems some 4 inches at least in the soil, as new roots will be made from them. Do not have too much border. If the soil be good loam three parts, the other part being well-decayed manure, and if it be 20 inches wide and from 6 inches to 7 inches deep, that will be ample. You can plant at 13 inches apart, keeping each plant rigidly to the one main stem only, pinching out all side shoots. Certainly press the soil firmly about the plants, and the whole of it also, but not over hard. Firm soil conduces to sturdy growth and to early blooming.]

Lettuces.—Although there are numerous varieties of Cabbage and Cos Lettuces in commerce, it is worthy of note that gardeners generally limit their main varieties to a good stock of Paris White Cos and a compact, white, smooth-leaved Cabbage form like All-the-Year-Round, a great favourite, Stanstead Park, or Leyden White Dutch. We see many very fine hearting Cabbage Lettuces tried at Chiswick occasionally, but very many of them when tasted are found to be very bitter. That is, of course, a great defect. The white-leaved Cabbage Lettuces usually are sweet and crisp, but crispness has much to do with rapidity of growth, for if the reason be hot and dry, and

water is not freely given, bitterness is likely to follow.—A. D.

Bean Johnson's Wonderful.—I was fortunate enough to secure a capital stock of this excellent Longpod Bean last year, and found it to be a splendid cropper. It is interesting to note that in spite of the run on the long-podded but sparse cropping Beans of the Seville type, especially for exhibition, that Johnson's Wonderful, quite an old variety now, holds its own. It would be interesting to see a fair trial as to the productive or podding capacity of this Bean and that of the best of the Seville or Aquadulce type. As a cottager's Bean for productiveness I prefer the former. Getting on plants double the number of pods found on the Spanish varieties more than compensates for their being somewhat shorter.—D.

Raising Tomato-plants.—Myriads of amateurs are now thinking of growing Tomatoes again this season, and naturally like to take the best course to lead to success. But too much haste in sowing seed is not a means to that end, as because the plants are tender and need warmth, seedlings raised in cool greenhouses or frames too early are apt to be stunted or to damp off. The first week in April is quite soon enough to make a sowing of seed, and that is best done in 5-inch pots, into which has first been put some drainage, then filled with moderately fine, light soil. Make small holes to the number of about fifteen over the surface of the soil with the point of the finger, drop seed into each, then cover with sandy soil. Each plant then as it grows finds ample room, till of necessity shifted singly into small pots. The seed will be helped to germinate if the pots be stood in a box 6 inches deep, and after being watered covered over closely with a large piece of glass, which should be thinly shaded on sunny days.—D.

Parsley.—As this is a hardy herb, and once raised stands well before starting into flower, a first sowing may be made at once in a drill beside a garden path, or in several drills 12 inches apart on a garden border. Without doubt, it is convenient to have a nice row of Parsley beside a footpath, as it can then be gathered by anyone without its being needful to tread on the ground. But in such a position it is not well to sow in poor ground. Rather dig in deeply a dressing of half-decayed manure, as Parsley roots will go deep in such case. The drill may be just shallow enough to enable the seed to be thinly covered. That should be sown thinly also, as if got in thick, material addition is made to the labour of thinning. If a good stock of the compost garnishing or the best treble curled be sown, and plants ultimately thinned out to 6 inches apart, very superior leafage in great abundance is produced. Plants giving the best quality of leafage alone should be retained. A similar sowing to stand the winter may be made early in August.—A.

Size of Potatoes for planting.—Now the season is with us when many people will be selecting or planting their Potatoes, there are many cultivators who are anxious to know how small they may plant their tubers. This is a question not so easy to answer, seeing much depends on how the tubers have been treated during the winter. Much also depends on the nature of the soil you are planting. I am aware that a good average sized whole Potato is the best, and I consider tubers from 3 ounces to 3½ ounces each large enough, and this is the size I should select for choice in a general way. Hardly too much importance can be placed on the care of the seed. This has been so often pointed out so ably by "A. D." and others in GARDENING ILLUSTRATED that I need not say more on this. Where the soil is poor I prefer a larger tuber than when otherwise. I have a field where I grow most of the main crop. This is under plough culture. Every year I select all the best and most even sizes for planting in the field, and what is over, if the kind is needed, the small ones are planted in the garden, the soil here being so much better and deeply worked that these small tubers often give twice the crop of those in the field. On several occasions, having new or scarce kinds, I have cut large ones to one eye, and also planted the very smallest in the garden, covering them with sifted soil, such as bird-potting soil, leaf-mould, etc., and have been astonished at the fine crop.—J. CROOK.

PLANTS AND FLOWERS.

ROOM AND WINDOW.

MICHAELMAS DAISIES.

THE return of certain flowers, long familiar, conveys to us in no unmistakable manner the story of the progress of the seasons. Scarcely, indeed, has the year been cohered in ere we are confronted with the blossoms of Aconite, Chionodoxa, Iris reticulata, and Snowdrops, and following in quick succession come Scillas, Grape Hyacinths, Crocuses, and Narcissi. We regard them all as Nature's own messengers. All through the piercing, uncertain March weather we thought of April sunshine and budding leaves, and endeavoured to banish from our minds the recollection of a long and dreary winter past. Now we find April as coy and fickle as ever, and dream of May and May flowers. We think of meadows where presently Colandines will cover all with their golden stars; of gardens where Tulips will soon be all

third season; but when some of these are fading there appears that typical blossom, the subject of our illustration, the Michaelmas Daisy. We recognise it as a forerunner of cold nights and misty mornings, when frosts may be expected, but its flowers are bright for all that. For how many years has it been planted in some of our gardens? More, perhaps, than we should care to tell; but, possibly, like many others, our interest in this "old timer" is not very deep. The plant has been kept certainly, because it fills a gap. We have, maybe, one variety, and that the well-known blue; others we have heard of, but have not added to our solitary specimen. May we, therefore, at this time, when planting may still be pursued, bring before the notice of readers the claims of these simple flowers—call them Asters, Starworts, Michaelmas Daisies, or what you will? We know that when their petals open the wealth of summer and autumn blossoms is practically ended. When gathered they lend themselves by their informality, needing nothing, as may be seen, to embellish them beyond a little of their own foliage, and the ease

large white, fine; N.-B. T. S. Ware, pale rose, large; N.-B. T. Smith, large blue; ericoides, white, small, centre yellow; Coombe Fishacre, flesh, very pretty; paniculatus W. J. Grant, bluish-white, rosy centre, effective; cordifolius major, lavender, large, all from 2½ feet to 3½ feet high; Novi-Belgii Top Sawyer, rosy-lilac; N.-B. Purity, white; N.-B. Margaret, pale blue; N.-B. Herpur-Crewe, white, early; N.-B. Ashley Smith, rosy-purple; Nova-Angliae procox, crimson-purple, early; levis floribundus, bright blue; levis Councillor W. Waters, pale lavender; Mont Blanc, white; turhinellus, violet, tipped rose; pendulus, white, Tradescanti, small white, with beautiful foliage, very useful for cutting, these last growing from 3½ feet to 5 feet high. LEAUCENT.

FLOWERS IN THE HOUSE.

(REPLY TO "GWYNNE")

To obtain flowering subjects in the window-box is comparatively easy, but to do so on the shelf you have set up "around the sitting-room" is another matter. For this latter, we think you had best secure some pot-grown examples of plants, such as the market growers supply of Ferns, Heliotropes, Agrostum, Calceolaria, Campannia isophylla, etc. Or you may grow the following in the room quite well, but it is desirable to secure plants fairly well established: Dracoea congesta, D. marginata, D. lineata, Aspidistra ltrida and its variegated form, commonly called "Parlour Palm." Of true species of Palm you may grow Kentia Belmoreana and K. gracilis, two of the best of all Palms for indoor work; also Corypha australis (nearly hardy), Phoenix gracilis, P. eriopala, Scaforthia elegans, Lstania borbonica, Chamsrops Fortunei, and C. exoala. Of Ferns you will find Adiantum formosum, A. cuneatum, Pteris tremula, P. oreitia, P. serrulata in variety, Polytichum proliferum, and Davallia canariensis as good as can be for the purpose, while Campanula fragilis, C. isophylla alba, Saxifraga sarmentosa, and Lysimachia Nummularia or Moneywort are the best of drooping or hanging plants.

In the windows you cannot do better than grow the plants first named—Heliotropes, etc.—and supplement them with Goraniums, Mignonette, Vallota purpurea, the white Arum Lily, Tuberosa Begonias, and such things in season. Stocks and Mignonette, as also Heliochrysums, Rhodanthe, etc., may be raised from seed sown in pots. The two first of these will require hot three or four plants in each 5-inch pot, while the others may be sown much more thickly. At this time all this can be sown in pots on the window-sill—or some, at least, for succession.

In the window-boxes you may grow Nasturtium, Marguerites, single Petunias, Verbenas, Stocks, Mignonette, Canary Creeper, Celosias, Indian Pinks, Poppies, Sweet Sultan, Sweet Peas, allowing them to hang down in front of the window, Antirrhinum, Fancies, Phlox Drummondii, Marigolds, Convolvulus, and many more from seeds sown thinly in the boxes in patches. If you adopted this view for the window-boxes that are outside, and plant at the end of April three Begonias of the tuberous-rooted section in each box at the back near the window, these would give a later supply of bloom, and also permit the seedlings in front to grow and flower unchecked for the time being. In sowing these seeds some care will be necessary, and some thinning also when the young plants appear, as also the clearing away of old stems when flowering is past. A good deal of attention to watering will be required. E. J.

Iris fimbriata.—This fine old greenhouse plant does not receive the attention which its merits fully justify. For the large conservatory or the winter garden, where the latter is kept at about 40 degs. or 45 degs., this plant is beautifully adapted. It may be grown in large pans or planted out in a deep and broad pocket on the conservatory rockwork, and in either find a congenial home. This plant should have attention generally, on account of its winter-flowering properties, as blue flowers are very rare in winter, and any plant so free growing and free flowering at this season cannot be too well known.

The Index to Volume XXIII is now ready, and can be had from the Publisher, price 3s.; post free, 3s. 6d. ILLINOIS AT URBANA-CHAMPAIGN

Arrangement of Michaelmas Daisies. From a photograph sent by Mrs. Hughes, Dalchoolin, Craighvan, Co. Down.

adams with beauty; but when we enter May and breathe the fragrance of the Lime we sigh for

"The grace,
The golden smile of June,
With bloom and sun in every place."

For, after all, is it not in these halcyon days when our gardens are most resplendent; when the very air is filled with Roses; when Pinke and Rockets show themselves; when Paeonies and Canterbury Bells, Poppies and Lupins, and hosts of other flowers add their quota of beauty; and when on every hand are to be seen the peerless blossoms of white Lilies. 'Tis in June when Nature puts on her fairest dress, when skies are blue, and when the atmosphere is soft and lucid; but when she has come and gone, and hot July gives place to the more sultry days of August, other blossoms appear which plainly tell of a further change. Then it is we get the first glimpses of autumn; faint perhaps may be the signs at first, but none the less surely. Some low trees have scarcely begun to don their amber garb ere the bright blooms of Gladioli, Phloxes, Hollyhocks, and Ranunculus all portend the approach of the

with which they may be grown in almost any garden should ensure them a still wider patronage. As we have observed, planting may be done now, but it should not be deferred a day longer than is absolutely necessary. We are under the impression that the pale blue variety which one often meets with, and which takes up a deal of room, when left for a few years has prejudiced many against Michaelmas Daisies in general, but from the list of sorts here given it will be noticed that not a few are comparatively dwarf, and it is to those who have small gardens and have not much room that we recommend them. Mention ought also to be made as to the abundance of spikes one may get from a collection, and coming in as they do, when, as we have said, other garden flowers are over, they are doubly welcome. The following are good kinds: dumosus horizontalis, reddish, suffused white; Masaki, deep lilac, early; ptarmicoides, small white; linoxyris, bright yellow; acris, lilac-purple; sibirica, mauve, late; all from 1 foot to 1 foot high; alpinus albus, white. Also, grandiflorus, blue, 1 foot; Novi-Belgii Rev. Eyles, purple-blue; N.-B. Madonna,

STARTINO HARDY ANNUALS AND OTHER FLOWERS.

(REPLY TO "DELTA.")

The idea of utilising the hot-bed for seed sowing of many annuals, biennials, and perennials is often overlooked. In many instances it is invaluable, not merely for the warmth generated by the manure, but equally so—if not, indeed, more so—by reason of the greater vigour which the seedlings on raised appear to have. The bed, that is composed of quite one-third leaves, not only much longer retains its heating power, but throughout it is found to be far more uniform, and therefore more serviceable and reliable. You may, therefore, with every confidence resort to the hot-bed, more especially because you have ample cool glass accommodation later on, so that the plants, young and delicate as they are, can be kept going at this important stage in their existence. In the nas of the hot-bed thermometer the temperature is taken when the instrument is plunged, and a bottom heat or bed heat, say, of 70 degs. may mean a surface heat of some 10 degs. less when minus sun heat. You would in such case not plunge the pots in which are sown the more quickly appearing annuals or biennials, all of which will obtain ample heat from being stood on the surface of the bed, surrounded as they would be in such a frame by a warmth that penetrates on all sides. On the other hand, any seeds of perennials may be much assisted in their germinating by the very presence of this moist, warm, ammonia-laden atmosphere. You will find a maximum temperature of 60 degs. quite enough, and you will need exercise some vigilance that the young seedlings be not surrounded by a rank steaming heat. Whether such is present or not will depend on the way and the materials of which the bed is composed. Rank team can always be modified by a 3 inch covering of fine ashes, or its equivalent, over the manure, and with ventilation afforded at the back. You will, however, have need to be careful as to watering, and when water is afforded let it be done thoroughly. Quite often this is fatal in its results; the amount of moisture, and of atmospheric moisture in particular, is so great that root moisture may be much lessened. In all cases sow the seeds in very sandy soil. See that liberal drainage is given to pots and boxes, and above all make the soil quite firm for the seed sowing. Soil that is quite firm permits of a more uniform passage of the water, while soil that is loose is as retentive of moisture as a sponge, and not only becomes so very quickly, but is in other ways a most unsuitable and uncongential rooting medium for any plant.

PLANTS FOR BED.

I HAVE a small piece of ground which I should like to plant with a few flowers to bloom through the summer and autumn, and if you would kindly advise me what to put in and when to plant I should feel much obliged. The situation is north of Manchester, fairly elevated; soil apparently clayey, and air slightly smoky.—WALKERS.

[The following plants will most likely suit your purpose. The first dozen are intended for the back against the fence. *Helianthus multiflorus*, H. m. fl. pl., H. Soleil d'Or, *Tritoma Uvaria*, *Aster Novae-Angliae pulchellus*, A. N. A. ruber, *Anemone japonica rubra*, A. j. alba, *Galaga officinalis*, G. o. alba, *Helenium nudiflorum*, *Echinops rothenticus*. The following will do quite well in front of the above: *Gaillardia grandiflora*, *Hemerocallis flava*, *Coreopsis grandiflora*, *Iris Mme. Chersau*, I. pallida, I. pallida dalmatica, *Dalphinium Belladonna*, *Pyrethrum Hemlet*, P. Sherlock, P. Mrs. Bateman Brown, *Rudbeckia Newmanii*, *Aster Amellus*, A. acris, A. levigatus, *Aquilegia chrysantha*, *Pyrethrum J. N. Twedy*, P. Aphrodite; while in the front row you may plant *Carnations* in variety, also *Heuchera sanguinea*, *Anemone sylvatica*, *Helleborus niger*, pink Hepaticas, blue Hepaticas, *Achillea mongolica*, A. umbellata, *Acmisra cephalotes*, *Geranium Andreasi*, *Iberis sempervirens*, *Phlox Nelsoni*, P. divaricate, *Lychis viscaria fl. pl.*, *Megasea cordifolia purpurea*, (*Euthera macrocarpa*). All the plants named are strictly hardy perennials, and may be planted at once. You will note the plants are given in three sets, so as to form three rows lengthwise, and by devoting these plants to the 25 feet at disposal sufficient room will be given for each. All the plants are quite hardy, and will come up again with greater

vigour. It is quite possible in the first year of planting there may be vacant spaces that eventually will be occupied by the plants given. If such is the case it will be in the first and second rows from front or between these rows, and for the present year you could introduce some showy annuals, sowing the seeds thinly in the open ground after the other things were planted. Such things may include Shirley and other Poppies, *Marguerite Carotions*, Stocks, *Mignonette*, *Godetias*, and others, or you may prefer some *Asters* for flowering in September. These you could obtain quite easily in young plants, and put them out in May. Another idea that would be showy and last a long time consists of *Tuberous Begonias* and *Tufted Pansies* planted alternately. A dozen of each planted in April would do well. The *Begonias* would have to be planted 2 inches deep or nearly so, while the *Pansies* could be dealt with in the usual way. An alternative scheme, if you wish for much colour at one time, would be single *Dahlias* for the back row, with a few *Sweet Peas* on the fence, filling the middle row with summer-flowering *Chrysanthemums*, and the front row with *Tufted Pansies* and *Begonias* alternately, as just stated. This, if you wish for an annual display, would be the simpler, but would need to be planted afresh each year.]

ANNUALS FOR TOWN GARDENS.

ONE of the vexations of the town gardener's life is that he is deborred from growing many plants that he would like to do, and experience has taught him that to attempt the cultivation of some herbaceous subjects, for example, is only incurring unnecessary expense and trouble, to end in failure. Under such circumstances it is not altogether surprising to find that after a time those who went in strong at the commencement for all kinds of plants gave up gardening as a bad job. My sympathy is extended to all who, though loving flowers, have to fight against conditions that are so fatal to such a variety of plants. The closed-in garden, the impure atmosphere, that parasite of all towns the sparrow, not omitting neighbours' cats, have to be taken into account sooner or later by the one who endeavours to brighten during the summer months the patch of ground at the back of his house. What to grow then will presently be the question raised by not a few who live in towns, and it is to these that I offer a few suggestions. Some people have an idea that to have anything like a display of flowers out-of-doors one is bound to have at the start a large number of "pot plants," which to the person without a greenhouse often means a considerable item. Turn over the leaves of a seed catalogue for a few moments, and look up hardy and half-hardy annuals. Five or seven shillings spent in the purchase of seed, a cold-frame at hand, some boxes, and a sufficiency of potting soil is all the stock-in-trade one needs at this time of the year. In the meantime, let it be understood that the borders should be improved as much as possible by being dug over, if that has not already been done, manure added to worn-out beds, and lightened if need be by fresh soil or some road-scrappings. Now as to

HALF-HARDY ANNUALS.

These should not all be sown at once; indeed, if one wants a long display of flowers, a week or more may elapse between the first and second sowings. It is sowing all the seed at once that accounts for many a garden passing from a blaze of colour to a scabrous within comparatively a few weeks. Soil for the boxes should be fairly rich and light, loam and leaf-mould and sand, the finest left on the top. Thin sowing must also be observed if strong plants are wanted from the first. The aspect of the frame, if one can have it, should be a south one, as it is there that one gets the benefit of every ray of spring sunlight. The time of sowing will all depend upon the locality in which one lives. It is advisable not to be in too great a hurry; the end of March or beginning of April for tender things will, generally speaking, be found soon enough. Some will benefit by any additional heat one may give them, and if one frame for the time being may be kept as a kind of intermediate place by partly filling it with old hot-bed materials, leaves, and stable-manure, then one may sow *Petunias*, *Verbenas*, *Zinnias*, *Lobelia*, *Phlox Drummondii*, *Ageratum*, *Salpiglossis*, and

Perilla. In the cold-frames those subsequently mentioned will succeed: *Jacobaeas*, *Marigolds*, *Godetias*, *Helichrysums*, *Tagetes*, *Asters*, *Stocks*. Out in the open, towards the end of March, a sowing may be made of *Pansies*, *Sweet Peas*, *Coronopsis*, *Mathiola*, annual *Chrysanthemums*, *Clarkia*, *Nasturtiums*, *Linum*, *Nemophila*, *Mignonette*, *Virginian Stock*, *Pyrethrum aureum*, *Convolvulus*, *Nigella*, *Candytuft*. In hardy annuals alone one has the run of a beautiful assortment, and if the garden soil is poor one need not give up the idea of attempting to beautify a town garden, for it is in a town where one needs most brightness. *Nasturtiums* and *Jacobaeas* will thrive and flower well in common and almost worn-out stuff. *Pansies* will bloom abundantly if planted in a little loam and road-scrappings. *Mathiola* will do equally as well, and give off an aroma that is sweetness itself. *Coreopsis* will flower in soil not always rich, and the same may be said of the small-flowered *Marigold*, *Tagetes*. *Virginian Stock* and *Pyrethrum aureum* both make pretty edgings, the one small and profuse blooming, and the latter valued for its golden-yellow foliage. Annual *Chrysanthemums* will keep the flower-beds full for many weeks, and *Sweet Peas*, sown in a rich compost, do fairly well in a town, and require nothing to keep up the supply. *Petunias*, *Verbenas*, and *Zinnias*, whether planted in beds (where they are often best seen) or grown in the borders, seldom fail to bloom well, and the last-named, though sometimes failing because of too early a sowing, when once they are succeeded with prove to be one of the brightest and most continuous-blooming of our half-hardy annuals.

Where one can give annuals even better advantages, such as purer surroundings and soil improved by manure, etc., few things, in my estimation, are more worthy of our trouble. They are not always given the best culture, some people, because they are annuals, thinking that a raking over of the soil and a scattering of the seed is sufficient. Those who propose growing annuals should give them every advantage if they desire the best results; they will be well repaid by increased blossoms, although they may live in a town.

TOWNSMAN.

PLANTING OUT VIOLETS.

VIOLETS are annually becoming more popular, and the introduction of so many fine single varieties has induced many to commence their culture. In spite, however, of the numerous cultural articles that have been written on Violets, one often sees them in an unhealthy condition and overrun with red spider. This is chiefly owing to planting them in too hot a position and neglecting to mulch and water them. I have frequently urged the importance of having strong, healthy runners, as failing these, good flowering plants cannot be obtained. Old plants divided and planted out do not, as a rule, produce either many or good flowers. To ensure these, good runners are essential. These should be well rooted before being planted out, as rootless runners invariably get crippled by cold winds in spring, and seldom make good plants. I do not advise the use of farm-yard manure for Violets, except where the soil is very poor. Old Mushroom-bed-manure, leaf-mould, the sweepings of walks and drives, and burnt garden refuse are the best ingredients. If possible, a change of ground should be given annually, otherwise a portion of the old soil should be removed and replaced with fresh, of as loamy a nature as possible. A semi-shaded position suits Violets best, though in low-lying gardens, or where the soil is heavy sod retentive, a sunnier position may well be given. The best lot of plants I ever saw was grown in an orchard, in the partial shade of Apple-trees. Plant in firm ground, and allow a space of 9 inches all ways between the runners. Single varieties require more room than double varieties, especially California, which is a very strong grower. Planting completed, screen the runners from cold winds by means of small evergreen branches, and keep them well watered. From the middle to the end of April is the best time for planting.

Daffodils from Cornwall.—I am sending a few specimen Daffodils, as I thought it might interest you to know what is growing in these parts just now. I have taken the liberty

of naming them, although you will probably know them all. In the course of the next fortnight I hope to send you some of the very rare kinds, many of which are not in the catalogues. I expect you have very many flowers sent you, but I hope you will not mind my sending these.

CHARLES DAWSON.

Rosemarian, Gulval, Penance.

[Many thanks. A very beautiful gathering, consisting of M. J. Berkeley, cernuus (handsome flowers), Victoria, maximus (true), Tsoy, and Sir Watkin, all showing how well the Deffodil does in the west of England. Enclosed also were several bunches of single Violets, the flowers large and excellent in every way.—Ed.]

CHRISTMAS ROSES.

Few plants are more universally admired than the Christmas Roses, as the forms of *Helleborus viridis* are usually called. Christmas Roses do best in the cooler conditions of midland and northern gardens, and away in the west again are as good as could be desired. The specimen plants that all would like to be possessed of

and hastened in the light soils over sand and gravel, I hardly know, but so it seems to be. Happily, near London, these plants are not difficult to manage, and indeed, within six miles of its centre, I have grown examples of the major variety 3 feet in diameter—not in a single plant but by dozens, and all alike. Near London these plants are much healthier in the more elevated districts—Hampstead, Sydenham-hill, and such like places. In these, with a little care, the plants make wonderful headway, never losing their leafage—an item alone that angurs well for the safety and the success of the plants. Plants in these hill gardens near London are vastly superior to the identical subject in the lower levels, and, indeed, when some have been transferred with every care to these lower surroundings the plants quickly dwindle away. In the lower the leafage is quickly disfigured and much loss being entailed, progress is barred. Frequently in the Middlesex fruit orchards plants have been seen, and always the nearer the river area the less foliage and less vigorous plants result. In some instances from the trees affording a welcome

Sweet Peas, the colour in this instance being white, with bright scarlet flakes, making a very charming and effective flower. A more robust variety is Mrs. Joseph Chamberlain, a very free-flowering sort. The blossoms, which are very large and handsome, are developed on a long and stout footstalk, and they are heavily flaked bright rose on a white ground. Of the three sorts we are here recommending, that just described is, in our opinion, the best. The trio may be completed with Gaiety, a splendid counterpart to the last-named except in colour, which may be described as striped rosy-magenta on a white ground. The constitution of this variety is all that can be desired, being most robust. The plants remain in splendid condition for some months if the spent blossoms be removed, and liberal supplies of water be given during the warmer weather. We should advise you to grow them in clumps, some 3 feet or rather more apart, sowing five or six seeds in each clump. If you wish to hurry on the period of flowering, you had better sow a like number of seeds in 5-inch pots, and raise them under glass in a gentle bottom-heat. Under this treat-

Christmas Roses. From a photograph by Mr. F. Mason Good, Winsted, Ill.

become somewhat of a rarity south of London, and particularly on the chalk formations, as the South Downs are approached. Here the plants are not usually happy. Not that the plant may not be made to thrive if the primary outlay for soil and preparation is faced. In such a case the natural soil will usually have to be discarded. It will depend largely on its composition and how near the surface is the impenetrable rock. If but a few inches of soil exist and then rock, it will be best to dig up or break up the latter to at least 2 feet deep and bring in good soil from a fresh locality. To insure success there should be quite 3 feet deep of soil—that is, of soil and drainage combined. With a deep root-run of good holding soil and shaded from the hottest sun, the Christmas Roses will not give much trouble when planted at the right time. And this right time appears, more or less, also governed by locality. In northern districts and generally in the Midlands, about Gloucester and Bath, these things transplant quite well in the month of March; but nearer London, and on much lighter soil, this time of planting them is most disastrous for the plants themselves. Whether it be that the action of the fibres is delayed in the cold rock medium, or that they

shelter the plants are better, and this is a welcome sign and no small object lesson of the value of overhead shelter for these things. Those who would make a festivity of them may plant in frames where scrim or canvas can be thrown over them in seasons of heat and of fog, and not less so at the time of flowering and the coming of the foliage in the early days of the year. This last is one of the important seasons, and at such times every encouragement should be given to the plants to do their best. An occasional dose of liquid-manure, or a dressing of some good fertiliser over the soil, lightly pricked in with the handfork, will all be helpful when the rains have carried its manurial properties down to the active roots below. Thus assisted a better growth and larger crowns, that in time bring their own reward, are insured.

E. J.

NOTES AND REPLIES.

Sweet Peas—three good striped sorts (R. S. K.).—In reply to your inquiry as to the three best striped Sweet Peas, we can recommend the following: America is now regarded as the most distinct of the striped

ment the seedlings should be seen above the soil within a week, and in the course of a few days the pots should be placed on shelves near the glass. In a few weeks the plants should be hardened off in a cold-frame, and when some 6 inches to 8 inches high planted in the clumps prepared for their reception.

Propagating Dahlias.—I have some dozen and a half *Cactus* Dahlias, and shall be glad of your advice as to propagating same. I have no greenhouse, hot bed, frame, or anything of a like nature. Under the circumstances, I suppose I must start the tubers in Cocoa-nut-fibre kept moist in a window, and divide the tubers as soon as the shoots are about 2 inches long, and, I suppose, pot same and keep them growing in the window until planting out time arrives? I know I can plant them whole in the ground, but wish to increase my stock. Will you please answer fully when to start the Dahlias, best time to plant out, etc., as I am sure there are many amateurs to whom the knowledge will be very welcome?—A. E. KNOWLTON.

[We are afraid you will not find much success in propagating Dahlies without some better accommodation than you now possess—at least, at this time of the year. You might strike cuttings made of the green shoots in summer, and prepare them for another season; but in attempt to strike them now without heat or to divide small tubers may end in spoiling the

whole. Young Dahlias, as a rule, have one crown giving only a very few growing shoots, but older roots lend themselves to division. You had better, we think, be content with your existing stock, and in summer secure some side-shoots and insert them round the sides of small pots. Do this early so that time is permitted for a tuber to form, otherwise your effort will be in vain. In the nurseries where Dahlias are largely grown they are started into growth in a warm house, and as the shoots issue and reach a length of about 2 inches they are taken off with a beel of the old tuber, and inserted at once into small pots, and kept in a close and warm atmosphere. Even provided with these conveniences they are some time in rooting. Division of the tubers specialists do not resort to, but depend on spring-rooted cuttings. If your plants are of two years' growth or older you may find when new shoots form that they can be split through, but be sure to see that a growing crown is on each division. The separate tubers are of no value without a crown, though on each there may be many. There would be no need to keep them indoors if they are of this age and condition, but rather divide and plant at once, making sure that the tender shoots are protected with a covering of soil. Later, when they emerge from the earth, protect with inverted flower-pots at night as a precaution against late frosts. This is all the trouble that need be taken with dry tubers. Newly-rooted cuttings are more tender, and must not be planted until May.]

Portulacas.—The need for a greater variety of annuals is frequently demonstrated. Some few sorts seem to monopolise what space is given up to annuals. One of the brightest and most free-blooming of our summer flowers is the Portulaca. It is too little known, and as a consequence it does not receive anything like the consideration it deserves. Its requirements are not great, and consist in sowing in pans in the house in March or April, and transplanting afterwards to the borders. One seed not, however, go to this trouble, for seed sown on a warm border in April will give a good show of bloom in July. For borders where the sun has much power and the soil is shallow, Portulacas are the best things one can plant.—TOWNSMAN.

ROSES.

ROSES IN WESTMORELAND.

AFTER many years of failure with Roses I have now found out how they may be grown here, or, rather, which kinds do well. It is high and dry, 500 feet or so above the sea, on a spur of red sandstone, jutting out into an upland valley, and not near the mountains. This has to be explained, for the climate is totally different and much milder in the "leke country." Another good plan is to try what you think yourself will grow and not take too much advice about it even from very experienced gardeners, who have not experimented in exactly your surroundings. As, for instance, one will say it is impossible to grow such and such Roses "with the peat in your soil;" another that "there is nothing like peat for Roses." So again I say, try for yourself. After doing this I can make the following remarks, viz., that the Austrian Copper Briars, Laurette Messimy and Mme. Lambert, all grow splendidly on my dry, sandy soil without the aid of loam from a distance, which I tried, again by advice, in the shape of clay; this failed to grow the Roses properly. The border where now they grow best was a spot where nothing did well, and which was hurled up in summer, a border facing south, protected by a low wall and paling only from the north. Here Mme. Lambert grows luxuriantly. Hardly do two flower alike. Side by side you may have a delicate pink, a deep red rose, and a yellow and white bloom, or one composed of all three shades of colour in one flower. Laurette Messimy is at its best in autumn, when the pointed pink and copper-shaded buds last longer than any other Rose, and only come to greater perfection after several frosty nights. So it is better to be laughed at and succeed than to have blanks in your Rose-bed where many lovely but too tender Teas cannot stand the bracing climate. The amusement of my friends consisted in seeing me plant as many Roses as I liked, and I think I

was right, for now I have Roses and before I had not. In summer the Crimson Rambler looks very gay on tall poles (Larch) and trained on another light lath from pole to pole. The Copper Briar, which I first saw at Vichy, in the Emperor's days, near an intermittent spring, and which his uncle's old soldier, who guarded the "sources," told me he had found in the forest of Orleans, is the sweetest and most effective as to colour of any Rose that grows; a mass of it is more brilliant than scarlet Geranium, and while the Crimson Rambler is showy but has no scent, the perfume of the Copper Briar is unrivalled. A hedge of it looks well, and I am trying it now in clumps among the Heather and Grass between the lawn and the Pine-wood. Lady Penzance is all very well, but not any of that class beats the colour of my favourite Briar. In this county the Crimson Rambler will not grow against a wall, as I have seen it do in Yorkshire, covering the station-masters' houses, and the Carmine Pillar does best with me in a Beech hedge. There are most lovely Tea-scented Roses, L'Idéal and Beauté Incertaine, but they do not last like those I have named in this climate. I planted my Roses in sandy, peaty soil with plenty of manure put in; the result has been exceedingly good. I am trying Soleil d'Or and Mme. Réal this year. The moral is—it is better in an uncertain climate to grow two or three kinds well than by ambition to be reduced to discouragement and failure because you cannot, however hard you try, succeed with Banksias and the heavenly Boule d'Or of the sunny south. Wire arches do not do so well for climbing Roses as Larch poles—the wire is said to attract the lightning—and pergolas may be made of wood, and are much prettier than the more formal wire. M. V. B.

BEST ROSES FOR MARKET.

(REPLY TO "J. McSWEENEY.")

We do not know whether you contemplate growing Roses under glass for market, but that is the only way in which this flower would be rendered remunerative at your long distance from London. There is always a glut of Roses in June and July, and the prices that rule then are very low indeed. You ask us which are the best Roses for market. If, as we said before, you mean for indoor culture, the selection is a very small one. Perle des Jardins is the best yellow. Some growers are using Mme. Hoste as a second best, the buds being long and of a beautiful soft creamy-yellow. Surtout is also a very attractive Rose, but does not sell so well as a decided yellow of the style of Perle des Jardins. Maréchal Niel, producing as it does only one crop, is not grown so very extensively. Most of the blooms of this Rose which are in the market now come from France. It would pay anyone to grow Maréchal Niel in a cold-house, so that the flowers open a week or two prior to the Roses outdoors. Of course, in Ireland you have some Roses outdoors early in June. You would find Maréchal Niel would fetch good prices at the end of May and early in June. The plants would need to be grown very cool to keep them back to this date. Saffron is another good market Rose, its lovely buds in winter being much appreciated. You should make it a study which Roses have the best appearance under the electric and other artificial light. It is such Roses that find the most ready sale. It is said among pink Roses that Bridesmaid is most appreciated, but Catherine Mermet, Mme. Jules Grolez, and Belle Siebrecht all have their admirers. Long-stemmed blooms of Catherine Mermet just now will realise 5s. to 6s. per dozen wholesale. La France, Carolin Teatout, Mrs. Sharnan Crawford, and Mrs. John Laing are pink Roses having considerable market value. Among crimson, Liberty surpasses everything. It quite eclipses General Jacqueminot, Papa Goutier, and others. Very early in the year the flowers of Liberty realised 12s. per dozen wholesale. It was raised in Ireland, although bearing an American name. Of white Roses Niphetos holds the palm, its pure buds being serviceable in so many ways. Kaiserin Augusta Victoria is a fine Rose, but requires care in handling. It should not be disbudded to any great extent, thus the flowers expand better, although they would be rather short stemmed. As to the time to plant, again we are not sure whether you refer to outside planting or

not. If under glass, during May and June is the best time to plant out pot-grown stuff, but if not in pots, then autumn is the best time. You must not force the latter too first year, but give them all the air possible. Supposing you desire to grow your Roses outdoors, then autumn is the best time to plant. All the kinds named should succeed outdoors, the Tea-scented being allotted the warmest corner. You will see further remarks upon growing Roses for market in the back numbers of GARDENING. If the trees are not too close you might grow Roses in an orchard, but you prefer as much morning and mid-day sun as it is possible to give them. For market we should certainly advise you to have a small plot of ground trenched for them well away from trees and hedges. Plant the several kinds named, adding Fisher Holmes, Ulrich Brunner, and Gruse au Trüpfitz to the reds, Mme. Abel Chateau to the pinks, Gustave Regia, Billiard and Barre, and W. A. Richardson to the yellows, and Souvenir de Malmesbury to the whites.

Roses—early pruning.—Many amateurs fall into the common error of pruning their Roses too soon, for, being anxious to give their gardens a neat, finished look, they cut to work and prune their Roses about Christmas. If one could be sure the weather would be seasonable no harm would result. I never prune until March is quite half way through, and then all the unseasonably made shoots will be pruned off and the lower buds will be still tightly folded up. By the time the plants start into growth April will have arrived, and more genial conditions may be expected to prevail.—J. GROOM, Gosport.

GARDEN PESTS AND FRIENDS.

Grubs in soil.—My leaf-mould is full of insects, specimens of which I send. Kindly let me know what they are, and whether injurious to young seeds or seedlings?—HENRY A. HARR.

I should be much obliged if you will kindly inform me what the grubs are in accompanying little box, and if they are injurious to garden stuff? I did not notice any last year, and think they must have come from the manure. What is the best way to get rid of them?—WORKER.

[The grubs in your leaf-mould are those of a two-winged fly belonging to the genus Bibio. To this genus belongs the St. Mark's-fly, B. Marci, so called from its frequently being very abundant about St. Mark's-day (April 25), and your grubs very probably belong to that species. They are large, very black, hairy flies, do not fly very well, and may often be found flying about in pairs. The grubs are injurious to the roots of plants, and I certainly should not plant young seedlings in soil infested with them. They could be killed by baking the mould, or saturating it with boiling water, or if placed where poultry could scratch it over they would soon pick out the grubs. I doubt if watering with an insecticide would be of any use.—G. S. S.]

Diseased Artichokes.—I herewith forward you a specimen of a diseased Artichoke. Kindly tell me what the disease is, and what is the cause? Is the soil too light and dry? Or have the tubers been planted too long in one place? Do they look manure, or is it the result of being dug up and pitted this year? Kindly say whether Artichokes will remain sound and healthy if taken up and pitted for winter?—ARTICHOKE.

[The Artichoke you sent was so covered with one of the common white moulds that it was difficult to determine what had caused it to decay and shrivel as it had done. The frost will not hurt these tubers if left in the ground, but it is possible that if exposed to frost under other conditions it might. In a "pit" each tuber would be partly surrounded by air instead of earth, which might make a difference, and the frost might be more felt. I carefully examined sections under a microscope, but failed to find any cause for the decay. Artichokes are so hardy that they will grow anywhere. The soil and cultivation are not likely to have been at fault.—G. S. S.]

Photographs of Gardens, Plants, of Trees.—We offer each week a copy of the latest edition of the "English Flower Garden" for the best photograph of a garden or any of its contents indoors or outdoors, sent to us in any one week. Second prize Half a Guinea.

The Prize Winners this week are: 1, Geo. E. Low, 2, Glenageary Hill, Dublin, for *Platycodon grande*. 2, Mrs. Hughes, Dalchoolin, Oungovan, Co. Down, for *Hydrangea* as a room plant.

TWO FRAME NARCISSI.

It would be difficult to find two more charming subjects for pot culture than *Narcissus monophyllus* and *N. triandrus*, and as their cultivation is of the easiest, and the bulbs will flower year after year, it is strange that they are not more often seen in amateurs' collections. The culture of *N. monophyllus* is as follows: Pot in August, placing bulbs 1½ inches apart, in a mixture of three parts light loam, one part coarse sand, with a fair sprinkling of small gravel stones; no leaf-mould or manure of any sort must be used. Water sparingly as soon as growth appears, increasing the supply as it proceeds, and keep continually moist until the flowers are over. The supply should then be gradually reduced, and about April stopped altogether. The pots should now be placed on a shelf in a frame or greenhouse, where they will be fully exposed to the sun, and should be allowed to remain there without watering until planting time. Annual repotting is quite unnecessary, once in three years being sufficient.

N. triandrus should be planted at the same time and manner as the foregoing, but the soil

This course of treatment is quite wrong. The plants require a rest after they cease to flower, it is true, but they should receive sufficient moisture to enable them to retain the old leaves until they begin to make fresh growth. They should also be accorded proper care, and instead of placing them, say, under a stage or similar place, put them in a cold-pit or frame instead to undergo a season of rest, and afford them plenty of air and just enough water to keep the foliage fresh until they begin to push up new leaves, which is the signal that the time for repotting has arrived. Plants now passing out of flower and given the above treatment will be ready for shaking out and repotting in June or early in July. For compost take one-half good fibrous yellow loam, one-quarter peat, one-quarter leaf-mould passed through a ½-inch sieve to free it of the rougher particles, with a pretty liberal addition of old mortar, crushed fine, and coarse silver-sand. The corms should be potted firmly, and when all are finished arrange them in frames facing the north. Until the roots make a fresh start keep the frames somewhat close and shaded also during the hottest part of the day, after which they are aired according to outside climatic conditions.

perature, as indicated above, they will, after being housed, quickly develop great quantities of bloom, and that of fine size and substance, and continue to flower for a long period. In proof of this statement I send herewith for your inspection and opinion a box of blooms gathered from corms varying in age from three to five years, and which have been flowering since last October.]

Very handsome flowers, large, and well developed on stout footstalks, the colours varying from pure white to crimson. The value of old corms was well shown at a recent meeting in the Drill Hall, where plants seven years old carried as many as 200 flowers, excellent in every way.

NOTES AND REPLIES.

Bouvardias.—The first batch of cuttings should now be ready, but before taking them off they should be examined, and if there are any signs of green-fly the house should be fumigated. This must be done carefully, as few subjects are so easily damaged by smoke as *Bouvardias* when they are making young growth, and it is even more difficult to fumigate

the cuttings, as the moisture in the propagating pit is against it. In making *Bouvardia* cuttings it is not necessary to cut them off close below a joint, as they will root from any part of the stem. Provided good, healthy cuttings can be had, there is little difficulty in rooting them. They require a good bottom-heat and a higher surface temperature than many subjects, especially for the early cuttings. It is essential to keep them from getting withered either during the process of making or after they are put in. If once they do get withered they are a long time making a start, and never seem to make much free-growing plants if they do start. It is easy to tell when they have made a start, and they should then be gradually exposed. Top the cuttings once before they are potted off, but they should stand in the cutting pots until they have started again. *Bouvardias* are often spoiled through not being treated liberally enough when they are required for cut bloom only. For early autumn flowering they may be planted out on a spot hot-bed, and when they get well rooted down they make strong growth and large trusses of bloom.

Humboldtia corymbiflora may be grown in pots, but should have plenty of root-room and a good, rich compost. All the *Bouvardias* should be grown fully exposed to the sun. They are naturally summer-flowering plants, but the flowering period may be regulated by stopping frequently. Although the same plants will keep up a succession of bloom for a considerable time, those required for late flowering should be stopped from time to time up to the end of September, and then if treated well they will go on flowering freely through the winter.

Growing on *Primula stellata*.—Last spring I sowed *Primula stellata*. The seeds germinated all right, but I mismanaged the plants by not keeping them near enough the light. They made little progress, the largest plants giving about twelve blooms in all (poor). They, however, seem to have recovered, and are now making rapid progress, looking very sturdy. I wish to know, if I keep potting them on and pinching out the flowers until August or September, if they will make a good show at Christmas? Or must I sow seed again, and try and manage better?—H. F. S.

[We think you would do far better to sow at once. The old plants may succeed, but it is very doubtful. You can keep them and do as you suggest, but young healthy plants give the best results in the case of single *Primula*.

Cinerarias in cold-frames.—I find there is a very general impression that green-fly is natural to this plant, and amateurs, who dread this pest, shy of introducing the *Cinerarias* to their greenhouses, lest they bring

The Bush Daffodil (*Narcissus triandrus*) in a pot. From a photograph sent by Mr. J. Rose, Rawlinson Road, Oxford.

should consist of loam three parts, leaf-mould one part, and a fair sprinkling of sand. The soil should be kept moist during the whole of the growing period, particular care being taken that the drainage of the pots is perfect. When growth is over and the foliage begins to turn yellow, the bulbs should be rested in a cool, shady place where the soil will not become dusty. The flowers shown in photograph are from bulbs which have been grown in pots and that have flowered annually for the past ten years.

Oxford. J. Rose.

OLD CYCLAMEN CORMS.

I WAS much interested in reading the remarks of "A. W." on the retaining of old *Cyclamen* corms year after year, and in getting such splendid results as 100 blooms on a single plant. Would "A. W." kindly give full particulars of the treatment and proper cultural method he alludes to for getting such good results, as, unfortunately, at present I have to be content with about a dozen blooms on each—JOE BONS, Penzance.

[Many ruin their old corms by neglecting them after they have done flowering. They are often cast on one side, perhaps placed under the greenhouse stage or in some out-of-the-way corner, with the result that the plants suffer from want of moisture, the foliage falls a prey to insects, particularly red-spider, and they eventually become entirely ruined. It is better to

The plants are also syringed twice a day, and on fine nights the saashes are drawn off so that they may have the full benefit of night dews, and replaced again the following morning. Watering, as a matter of course, has careful attention, as they must neither be allowed to want for moisture or be kept in a sodden condition. Under such treatment the old leaves are gradually superseded by fresh stout, healthy ones, and in the course the crown of the corm will bristle with flower buds.

Towards the end of August or middle of September the plants are ready for housing, and are then separated into two batches, the forwardst being placed in a house having a day and night temperature of 60 degs. and 55 degs. respectively, and the remainder in a slightly cooler situation to bloom later on. Feeding commences as soon as the flowers begin to push up, and this consists of liquid-manure and Clay's fertiliser. These stimulants are administered, as liberally as is consistent with safety, on every occasion that water is required, the liquid being used for a few days and then Clay's fertiliser, as the *Cyclamen* likes a change of food. If the plants are stood where they have plenty of light, and in addition have every attention in the way of watering and feeding, and subjected to a steady day and night tem-

the fly with it. After growing *Cineraria* for many years, I think the attacks of fly are very greatly exaggerated, but I do not in the least dispute the fact that many growers suffer severely from it, as I used to be continually fumigating to keep plants clean so long as I depended on artificial fire-heat to keep the frost out. Since I have grown them in cold-pits, and relied solely on mats and litter to keep the frost out, I have had no fly at all. I was led to adopt this plan by going into an amateur's small back garden some years ago, and seeing some of the dwarfest and healthiest *Cinerarias* I had ever seen. On inquiry as to how they were kept so healthy, with leaves down on the pot, I was shown an ordinary Cucumber-frame set on a bed of coal-ashes where these plants had passed safely through a severe winter. Since then I have never put my *Cinerarias* in a glass-house of any kind until they come into flower, but have kept them through the winter either in pits or frames, covered at night with mats, and opened and ventilated directly the frost was off. It takes a good deal of time covering and uncovering, but I can assure anyone that needs really good plants that he can grow them well without any artificial heat.—JAMES GROOM, *Gosport*.

Sweet-scented greenhouse flowers.—Sometimes one misses, on visiting green-houses of friends in the summer, the fragrant flowers one has been accustomed to, and notices a disposition on the part of some to grow blossoms whose beauty alone is their only feature. Whether this obtains to a very great extent I am not prepared to say, but during the next few months, when a good number of plants are being prepared for the beautifying of houses, one should endeavour as far as possible to grow a proportion that are best known and appreciated for the fragrance they yield. There is, on the other hand, a danger of leaning too much in this direction, when, as in the case of highly-perfumed blossoms like *Hyacinths*, the smell is overpowering, but one may, even as regards a matter like this, strike the happy medium. Fragrant flowers like *Heliotropes*, *Musk*, *Nicotiana affinis*, *Freesias*, *Mignonette*, *Petunias*, *Lilacs* in variety, and *Tuberose* should have a place in all greenhouses.—TOWNSMAN.

Grouping *Hyacinths* in pots.—I doubt if any other bulb is used so extensively in the garden as the *Hyacinth*. When grown in pots the large-spiked kinds are generally potted one bulb in each pot. For many purposes they are most useful in this way. In many instances when a single bulb is used in a vase the effect is poor. Recently I have been using in low vases three bulbs grouped together, with the best results. It is an easy matter to grow them in moderately fine soil, and when coming into bloom to wash the soil from the roots, placing them in the vessels they are to remain in while in bloom. In this way all the spikes are in beauty at one time, and when roots are filled in with sand and the pots mossed over, the spikes need no staking if they have been well grown. Some thirty years ago I remember seeing in a large garden in Wiltshire good-sized pots with five and seven bulbs in a pot, and grouped as these were on the floor of a conservatory amongst the spring-blooming things, so fine was the display that I have never forgotten it.—J. CROOK.

Cleaning houses, pits, and frames.—Many amateurs do not give much attention to this important work. In every instance it is well to wash all glass and wood, and now is the best time to do the work. I have been troubled with mealy-hug on the *Vines* ever since I have had charge of this garden, and it is very difficult to keep down with having to take stove plants into the *Vines*. The last three years I have painted all the wood and iron with paraffin oil, lime-washing the walls, etc. From the *Vines* I remove all loose bark, then scrub every bit of the *Vine* with a scrubbing brush, using *Abol* insecticide, applying it in as hot a condition as the hand will bear it. After two or three weeks the *Vines* are gone over a second time in the same way. By this method I have well nigh exterminated it in a far more effectual way than when I painted the *Vines* with lime, soot, mud, and some insecticide—the common way in gardens. It is important that all the top soil should be removed to clear of any insects in it.—J. CROOK.

ORCHIDS.

MEXICAN ONCIDIUMS.

THERE is no class of Orchids more free-flowering or attractive than the Mexican section of *Oncidiums*. The best among these are *O. Forbesi* (the subject of the accompanying illustration), *O. crispum*, *O. pratense*, *O. Marshallianum*, and the various natural hybrids that appear amongst importations of the above-mentioned species. These may be procured at a modest outlay, and, as they usually travel well, are generally placed upon the market in good condition. They are admirable subjects for amateurs who have a warm greenhouse or a cool intermediate house. They usually do well, even under most unfavorable conditions, for a few years after they are first imported. They cannot be classed among the long-lived section of Orchids. The cause of this will no doubt be found in the free-flowering characteristics of these *Oncidiums*. This, combined with the lasting qualities of the flowers and the selfishness of the grower, who thinks more of preserving the flowers to the longest possible moment, instead of removing the spike as soon as it has been expanded a reasonable time,

Oncidium Forbesii. From a photograph sent by Mr. J. Cox, 13, Haydon Park Road, Wimbeldon, Surrey.

causes undue stress on the pseudo-bulbs, and the result is apparent by the annual deterioration of the plant.

CULTURE.—The plants are best accommodated in baskets or shallow pans, well drained with broken potsherds. The compost suitable for them should consist of fibrous peat and Sphagnum Moss in equal portions, or they may be grown in leaf-soil, consisting wholly of Oak or Beech-leaves. This should be pressed moderately firm, and the surface should be covered with living, chopped Sphagnum Moss. A great deal has been written of late in the gardening press about leaf-soil for Orchids, but I cannot agree with its general use. It suits some plants, the above-mentioned *Oncidiums* being perhaps the chief.

H. J. CHAPMAN.

"Farm and Home Year Book."—We are glad to be able to state that the "Farm and Home Year Book" seems to have met a want felt by our readers. Its reception by the Press generally has been most cordial, and the demand for it has been so great that a third edition has been issued. Our readers should have no difficulty in obtaining it from any local bookseller or newsagent, who will order it if it is not in stock; or they may get it direct from the Publisher, 17, Farnival-street, Holborn, E.C., by post, for 1s. 6d.

CHRYSANTHEMUMS.

SOME OF THE BETTER JAPANESE SORTS FOR CUT FLOWERS.

WHITE Japanese Chrysanthemums always find a more ready sale than those of any other colour. The plants which develop the large white exhibition blooms are not necessarily the best varieties for making a free display; nevertheless, many of them are well adapted for this system of culture, and the following sorts may be regarded with favour. The varieties in the subjoined list embrace those blossoming from the early days of October till the end of the year and even later.

MARKET WHITE.—A beautiful free-flowering pure white bloom of drooping form. If partially disbudded the blooms come of a useful size, with a good length of footstalk. Height about 2½ feet. In bloom early October.

MYCHETT WHITE.—This is a fine flower. In late September and early October it is in superb condition. The plant is a rather difficult one from which to obtain stock, but by planting old stools under glass in a light compost success is assured. Height about 2½ feet.

QUEEN OF THE EARLES is a pure white

sort, the blossoms when well grown being very handsome. To be seen at its best the plant should be stopped two or three times during the growing season, this treatment producing specimens of a bushy character. In flower late September and October. Height about 3½ feet.

BARBARA FORBES.—This is another sort that has not attained the notoriety its merits deserve. The blooms are large and pure white, and the variety is seen to advantage when the plants are disbudded to about a dozen blooms on each. In flower October. Height about 4½ feet.

WHITE QUINTUS.—Of the many excellent October white-flowering Japanese sorts this is one of the best. It develops blossoms all the way up the stem, which is crowned at its apex with a cluster of dainty flowers of superb form. Height 3½ feet.

GLADYS ROBIT.—This is another pure white sort of unique form, and, to be seen at its best, should be disbudded to about a dozen blooms on each plant. Period of flowering late October. Height about 3½ feet.

MME LOUIS LEROY.—Although introduced some ten to twelve years ago, there is much in this variety to commend it to growers of free-flowering sorts. The plant is rather taller than some growers would desire, yet by

two or three stoppings its height may be considerably reduced. Late October and early November see this variety at its best.

MILLE LACROIX.—This is another of the older introductions, but withal a very lovely variety when the plants are grown freely. The somewhat small blossoms are very dainty in appearance, their whiteness being of a glossy kind. Habit bushy and free flowering. Early November is its period of blossoming. Height 4 feet.

EMILY SILSBURY.—A very charming pure white bloom, developed on plants about 4 feet high. By a rigid system of disbudding, a goodly number of large blooms may be obtained; when freely grown, however, it is useful for cutting, etc. Period of flowering late October and early November.

LADY BYRON.—This is a well-known sort for producing large, handsome blooms, but by a system of pinching or stopping, and also partially disbudding the resulting terminal buds, pretty pure white blossoms may be obtained in November. Height from 5½ feet to 6 feet.

LADY ELLEN CLARK.—In this instance the plant should be accorded treatment similar to the last named. It is a variety of easy culture, and should be disbudded. Pure white. Height about 5 feet.

MILLE A. DE GALBERT.—This is another of the one-time popular exhibition sorts. It is a handsome flower, and when grown in a free manner, charming. The blooms are pure white, with rather broad florets, and when the plant is subjected to pinching or stopping develops into a bushy specimen. Height about 6 feet. In bloom during late November.

MRS. C. BOWN.—A plant of Australian origin, and useful for all purposes. Its colour may be described as pure waxy-white, with a greenish centre to the large, full bloom. Height quite 5 feet. Late November.

WESTERN KING.—A lovely incurved Japanese bloom of glistening snow-white. The plants of this variety will carry eight to twelve very handsome blooms. Period of flowering late November and early December. Height about 5 feet.

SOUVENIR DE PETITE AMIE.—This may be had in bloom at almost any time by a varied system of culture, and also a differing period of bud selection. Pure white, large flower, bushy habit. Height about 3½ feet.

NELLIE POCKETT.—This, recently figured in these pages, may be described as pearly or waxy white. Should be pinched or stopped on a few occasions and disbudded. In flower late November from terminal buds. Height about 5½ feet or rather more.

MISS ALICE BYRON.—A handsome pure white sort of recent introduction, and invaluable for December use when grown freely. Cuttings inserted in March and April and grown on carefully develop charming plants bearing chaste blossoms of a useful size when partially disbudded. Height about 4 feet.

MME. PHILIPPE RIVOIRE.—A fine late variety, of an ivory-white colour. It is a plant possessing a good constitution, which is an item of importance in late-flowering kinds. For December use it is reliable. Height about 6 feet.

MME. THERESE PANCOUCHE.—This variety is regarded as the best of the late sorts by many growers. The blooms are large and handsome, and are also developed quite freely. Late December and early January often see this grand sort at its best. Height about 6 feet.

MME. CARNOT.—This, so popular as an exhibition sort, answers well when grown on to terminal buds and flowered freely. It is unfortunately a very tall plant, but by a series of pinching may be considerably reduced in height. It has pure white blossoms of a drooping character, which are highly valued during the period of flowering.

WINTER QUEEN.—Late blossoms of this plant are pure white, and when the plants are partially disbudded they develop blooms of useful proportions on stout, erect footstalks. Good habit. Late January see the blooms in good form. E. G.

NOTES AND REPLIES.

Early-flowering Chrysanthemum "Orange Masse" (Propagated) by you wrong in supposing this plant to be a sport from

one of the members of the Mme. Marie Masse family. We quite agree with you that the naming of this plant is very misleading to those who know little or nothing of its history, and it is a great pity that the name of "Masse" should be associated with this plant, seeing what an excellent lot of sports from Mme. Marie Masse is now being distributed. The variety under notice is really a seedling from Mme. Marie Masse, and may be classed as a very beautiful flower of a rich orange colour, tipped golden-yellow. The plant is rather taller than those of the family of plants referred to, but it is a distinct acquisition.

Chrysanthemum—how to make bushy plants for November flowering (T. G. H.).—You cannot do better than commence stopping your plants at once. You will find

of culture is very simple, and if the rules as laid down previously be carefully observed the plants should flower freely. When the terminal buds are developed they should be slightly thinned out.

FERNS.

THE ELK'S HORN FERNS.

THE Elk's or Stag's Horn Ferns (*Platycerium*) are in growth and aspect quite different from all other Ferns. Instead of finely cut fronds of tender siliage work, as in the Maiden-hair Ferns, for example, the Elk's Horn Ferns have thick and massive leafage, or rather combinations of leaf and stem of a leather-like texture, often silvery when young, changing to a dense

Platycerium grande. From a photograph by Mr. Geo. E. Low, Dublin.

that much better results will follow if you pinch out the point of each of your plants which has attained a height of some 6 inches or rather more. This will cause the plants to develop lateral growths in the axils of the leaves, and from these resulting growths the stronger-growing ones should be retained and subsequently treated to a vigorous system of culture. When these branching shoots have reached a length of 6 inches they may be pinched in a similar manner. The resulting shoots from this pinching of the growths will need to be treated similarly, as the subsequent growths attain a length of 6 inches to 8 inches, more or less, and by these means a large, bushy plant may be developed. For a November display, however, the last pinching of the shoots should take place about the third week in June, and from this point the shoots should be grown on and flowered from terminal buds. This method

dark green with age. There are about a dozen forms or kinds, found for the most part in Eastern and Australasian regions, where they grow in an epiphytal manner on trees, or now and then on rocks and boulders. This kind most often seen in greenhouses, or even in sitting-rooms, is

PLATYCERIUM ALCICORNE, introduced to British gardens about a century ago from Queensland and Polynesia. Its fertile fronds grow from 1 foot to 2 feet in length, and fork in a twin or dichotomous manner, and in colour are of a soft grey-green. They spring in tufts from the centre of the rounded or shell-shaped barren fronds, which are of a paler green colour when young, and turn to a rich reddish-brown as they decay. The barren flange-like fronds clasp the trunks or branches of trees, on which they grow in a wild state, or the pots, pans, or wooden blocks in or on which they are grown in our

gardens. If a plant of the common Elk's Horn be grown in a flower-pot, it may, when well established, be suspended upside down by a wire support, when the barren fronds will clasp the sides of the inverted pot, and the fertile leafage will clothe the pot in a very pretty and natural-looking manner. One of the best kinds is

P. ANTHORICUM, better known in gardens under the name of *P. stemmaria*, which comes from the Guinea Coast and Angola. It can be grown on thick slabs of wood, being fixed securely with copper nails and wire, along with a compost of fibrous peat, earth, and a little living Sphagnum or bog Moss. It enjoys a high and moderately moist temperature and a half-shady position. Another very noble species is

P. GRANDE, from North Australia, which produces much divided, strap-like fronds, often hanging down in masses 6 feet to 7 feet below the block on which it grows.

P. BIFORME is a dwarf and sturdy kind from the East Indies, with very thick and blunt or rounded fronds of a dark green colour. *P. Hillii* was sent to Europe from Queensland in 1873, and is probably only a geographical form of *P. alcinorum*.

P. WALLICHI AND **P. WILLINGII**, the one from the Malay Peninsula, and the other Java, are both very handsome, but are not so often seen as are the other kinds named. The latest addition to the group is

P. VEITCHII, introduced in 1896, of erect and sturdy habit, with stiff, erect, dark green fronds.

CULTURE—All the kinds, if we except the common *P. alcinorum*, require a warm or hot-house temperature, and look very handsome if the blocks on which they grow are hung on the dark velvety brown stems of the tropical Tree Ferns. They are usually increased by division, but some of the kinds produce viviparous buds or bulbils on their roots, from which young plants are more readily, or at any rate more quickly, obtained than from spores or seeds. Even individual plants are very effective, but a group or collection of all the kinds, as seen on the damp end wall of a plant stove, is a sight not readily forgotten. At home in the tropics these plants form dense masses on the forest trees beside rivers and creeks.

V. B., in *The Field*.

FRUIT.

GRAFTING TREES.

In the process of renovating old or perhaps worthless fruit-trees, re-grafting must play an important part. The work needs a certain amount of practical knowledge and expertise, but, still, it is not difficult to do by any intelligent person. We have seen Apple grafting done on pieces of roots of old trees by the fire-side in winter, the work being neatly done, and in all cases at once buried in the soil, leaving only the point of the scion exposed. That is not, however, a very excellent method, and, generally, it is far better to graft growing stocks in their proper season outdoors than to attempt that form of root grafting. But in renovating old trees, no labour should be wasted over those which have become exhausted, these being best grubbed out and destroyed. Still, there are many fairly clean, healthy trees found that crop well or badly, but the produce is at the best an indifferent that it has little or no market value, and will never repay for cultivation. Such trees present the very best of material for re-grafting, and were tens of thousands of such in the country but beheaded and re-grafted with good, fine, fruiting varieties that have market value the gain would be enormous.

Whenever it is purposed to so graft old trees the heads may be lopped at once to within 3 feet of the height at which it is purposed to insert the grafts. The final beheading can be done when the grafting is done. Whenever that is so the greatest care should be taken, not only to select places free from knots or branches, but also that the saw cuts be clean and there be no tearing of the bark. That can always be avoided by causing the saw to cut through the underside of the stem an inch or so in depth first, as by so doing the danger of bark tearing is avoided. But if the larger portions of the

branches be cut off and faggoted now, the rest can remain until the first week or so in April, by which time sap should be rising. The next matter of importance now is to secure grafts or scions. These should be of stout, hard shoots of last season's growth, and when cut from the trees of the good varieties it is desired to work on to the old stems of others, should have the lower ends made even, be tied into bundles, each variety separate, and labelled with the proper name, then be laid in fully 6 inches in depth under a north wall or fence, only the tops being exposed. So cared for the grafts are kept dormant, and are in that condition better fitted for grafting than would be the case were these so active in pushing buds on the trees on which to be worked at the time. When wanted for grafting a rise under the pump soon washes off the soil. Ready for use, also, should be secured a quantity of well-prepared clay for coating the graft joints. This should be nearly dry, well broken, free from stones, and have mixed with it one-fourth its bulk of clean horse-droppings, well beaten up, mixed, then moistened to get it into the proper plastic consistency. When so prepared, the clay should be smoothed over and covered up closely to keep it from drying. In making the final severance of the large branches on the tree to be grafted, it is best to do so about 2 feet or so from where they break out from the main stem. It is better to graft low down, putting in each three or four stout grafts, than to put in a couple 3 feet or 4 feet higher up, as the growth is so much stronger and a far better head is produced. Grafting may be done by simply inserting the scions under the bark; but with stout grafts cutting a small wedge-shaped piece out of the hard wood, and shaping the graft to fit it, enables the best work to be accomplished. It is work in which, with all proper materials, practice soon makes perfect.

A. D.

NOTES AND REPLIES.

Spraying with caustic alkali solution.—Will you kindly inform me if it is safe to spray fruit-trees in an orchard where sheep are grazing with the caustic alkali solution composed as follows: 1 lb. commercial caustic soda, 1 lb. crude potash, 3 lb. common treacle, 10 gallons water? Or whether there is a risk of some of the sheep being poisoned?—A. W.

[There is not the slightest risk of the sheep being poisoned through the use of the caustic alkali solution named by you, because if the spraying is properly carried out the small quantity of chemicals that would be deposited on the Grass would be so infinitesimal that it could not possibly do any harm. It would, however, be a good plan, seeing that the solution is of a very caustic nature, to remove the sheep while the spraying is being performed, and put them back again next day, or so soon as the whole of the trees have been sprayed. As the season is far advanced you should lose no time in getting the trees sprayed, otherwise injury may result should there be Plums, Damsons, or Pears in the orchard. Apples, being later in developing their blossom buds, are yet safe.]

Vines in tubs.—Outside the conservatory are gravel paths and a lawn. Would Vines in tubs inside conservatory do any good? The conservatory faces south, and has plenty of room for a couple of Vines. 2. The best Vines to grow in tubs without heating apparatus? 3. Is it too late to plant them now?—F. A. M.

[Usually Grape growing in tubs is not a success, but given careful treatment they may do for a time under this root restraint. The nature of the roots, however, is such that the Vines do not long remain productive when limited to such small areas. Good turfy soil is absolutely necessary, this being enriched with some half-decayed cow or horse manure, to which are added a few half-inch bones and a little Vine manure. The Black Hamburgh is the best variety to grow without heat; Foster's Seedling being a very good white Grape as a companion. There is yet time to procure strong fruiting canes from the nursery, which when being planted should have the soil made firm about the roots. Drainage is all-important, and should be ample without being excessive.]

Treatment of Vines and Peach-trees.—Would you kindly tell me when to withhold the syringe from Vines and Peaches that are being forced? Also, when to stop Vines? My Vines are just showing their embryo bunches, and are very vigorous. The Peaches are just over blossoming, and are forming little fruits. Any other information for future guidance would be obliged.—CANTANT.

[Under ordinary conditions Vines do not require to be syringed, Some Growers never

resort to syringing at all; others do so until the buds have developed, and until towards the flowering period, when it is discontinued. With proper attention to the ventilating and heating of theinery there is no need for syringing; atmospheric vapour can be maintained by frequent damping of the floor, and this is equally, if not more, beneficial to the occupants of the house. The laterals should be stopped at one, two, or three leaves beyond the bunch, according to the space at disposal; sub-laterals following this will also need to be pinched periodically at their first joint. Vines that are in a very vigorous state need very careful manipulation of the laterals; if kept too hard pinched the basal buds may be forced into premature growth, but if they are carrying a full crop not much excess of leaf will result. Peaches just passing out of their flowering stage will now require attention in disbudging the shoots and thinning of the fruit. You will find in the issues of GARDENING ILLUSTRATED for March 15 some instructions on disbudging Peaches, so that this need not be repeated; but the fruits when thickly set will need reducing in accordance with the numbers now developing. An old rule was that one Peach to each square foot of trellis is ample for a crop. Nectarines, being smaller, may be left a little more closer together. Some of the smaller kinds of Peaches may have slightly less space allowed between the fruits. Always choose the fruit on the upper side of the bunches for your crop, removing those situated beneath the trellis. Do not, however, be in too great a hurry in thinning down your fruit to this extent, because, though the fruits may now appear to be swelling freely, they may go to the size of Filberts, and then some of them collapse. Thin them down by a daily graduation, and when it is seen they are beyond their critical stage, then reduce finally to the desired number.]

Scale on Currant-trees.—Many of my Red Currant-trees in a north aspect and nailed to an old wooden shed are covered with scale. So also are some of the Gooseberries and Currants in another part of the garden. I have not noticed it before this year. The Gooseberry-trees have always borne fruit profusely and ripened it well. The Currants generally drop most of their fruit before it ripens. Can anyone tell me whether this is a common disease, and whether trees infested by it should be destroyed?—NEWLANDS.

[It is not usual for Currants or Gooseberries to become attacked by scale—at least we have not found it to be so—and we should certainly think, in the case of the Currants, that it would be much more economical to root them out and replant with young trees, rather than waste time on those which have lapsed into a state such as you describe. Both Currants and Gooseberries can be purchased so cheaply, and they so soon come into bearing, that there is no need to waste time in trying to retrieve their former health and state. Young bushes are more vigorous and bear much finer fruit. Before planting, however, we should advise in the case of the Currants growing against the shed, that the soil be removed to at least a yard in width and proportionate depth, and this replaced with fresh—not necessarily from a distance, but that which is fresh to tree-roots. A wash made with concentrated alkali is most effective for use on trees in a dormant state to destroy insect life. Soluble paraffin-oil, too, is also good for the same purpose. Flowers of sulphur made into a paint with water or skim-milk and this applied to the trees with a brush in dry weather will often prove fatal to scale, and is quite harmless to the trees. Without evidence to the contrary, we should think there must be extreme debility in such infested trees, calling for fresh soil with preferably some good solid farmyard-manure. In any case this would do much good, and could not possibly harm the trees.]

Root pruning fruit-trees.—Those who have not seen this operation skilfully performed must not suppose that root pruning means a general cutting away of all the roots which extend beyond a certain line and then filling the trench in again. The proper way is to open out a trench at the extremity of the principal roots, and then with steel forks to work inwards until a goodly number of the strongest roots have been traced to within a reasonable distance below the surface of the border. These will then require slightly cutting back with a sharp knife, and the work of relaying in fresh loam, which must be made very firm by ramming, will follow. At the trench is filled in again. If the

old compost is really good, a small quantity of fresh loam will suffice, and the addition of manure, as a mulching only, will complete the operation.

TREES AND SHRUBS.

THE RESULTS OF THE RECENT FROST ON BAMBOOS AND SHRUBS IN THE NORTH OF IRELAND.

(TO THE EDITOR OF "GARDENING ILLUSTRATED.")

SIR,—The recent very severe frost, which lasted about ten days here, with a temperature of 25 degs. of frost on some nights, has seriously affected many shrubs and plants which hitherto had shown themselves perfectly hardy here. Probably, however, as a very heavy fall of snow, averaging about 14 inches in depth, marked the commencement of this period of cold, and did not thaw until its close, the roots have escaped unharmed. The hardy Bamboos in this collection have been variously effected, and some have unexpectedly withstood the severe stress better than others which have hitherto enjoyed a greater reputation for hardiness. *Arundinaria nitida* and *Bambusa palmata* appear perfectly unaffected, though in exposed positions, and the latter in low damp ground at the edge of water, as well as in partial shade of trees. *Bambusa Veitchii* also seems to have withstood the frost well, but it is in a sheltered position. *B. ruscifolia* (viminalis), probably protected by snow, comes next in order of hardiness, showing very small traces of withering. *Phyllostachys heterocycla* shows fronds only slightly withered. *Phyllostachys nigra* and *nigro punctata* though much withered have come through fairly well, the latter perhaps the better. The dwarf *Arundinaria Fortunei aurea* has escaped pretty well, perhaps owing to the covering of snow. But all the species in the following list have their frondage completely withered and browned. *Arundinaria Khaziana*, which is a species apparently nearly allied to *A. nitida*, and which has come through some previous severe winters unharmed, now has its foliage destroyed and falling off. I cannot make out from the Kew list whether this is *A. Khaziana* (Munro), but in character it may be placed between *A. falcata* and *A. nitida*, and is of a very vigorous habit and most elegant appearance. Then follow *A. japonica* (Metak), *Simonii*, *Hindii* var. *graminea*, *Phyllostachys amra*, *Quillioi*, *mitis*, *crustilloniæ*, *flexuosa*, *viridis glaucescens*, *Merlicæ*, and, of course, *falcata*, which is deciduous every winter. The above list comprises the only twenty hardy species of which I have large enough plants to enable me to judge.

Some notes respecting the behaviour of other shrubs may prove also of interest. *Olearia liasii* and *stellulata* (Guianens) have come off well, but *O. macrodonta* and *O. Fosteri* (the latter usually extremely hardy) have their leaves quite blackened and falling. The genus *Elaeagnus* has, for the most part, escaped unimpaired. Among evergreens *Staurontia hexaphylla*, *Cleyera japonica* (why is this charmingly tinted shrub not generally grown?), *Raphiolepis japonica*, *Daphniphyllum macro-podium variegatum*, and *Choisya toroata*, have escaped well, and, to my surprise, *Nandina domestica* and *Engenia apiculata*, which is against a wall. *Griecelinia littoralis* is quite as bright as ever, and *O. lucida* var. *macrophylla* is almost unscathed. But when I mention that standard hybrid Roses have been killed, most Tea Roses on their own roots cut down to snow level, and even the common Monthly Roses and *Azara microphylla*, against walls severely damaged, it will be seen that the test has been a very severe one. W. DE V. KANE.

Drumreeke, Monaghan.

NOTES AND REPLIES.

Moving the Winter Sweet.—I have a Winter Sweet (*Chimonanthus fragrans*). It is in a bad situation, and has only had two or three flowers. I want to move it to a more sunny place. Will it bear moving? Is this the best time to move it—just after it has flowered? When should it be pruned?—OULAN.

[Yes, you had better move it at once, taking care that in the event of dry weather it is well watered, and also freely mulched to prevent evaporation. It requires very little pruning.]

Lonicera fragrantissima—A large bush of this has, until the recent hard frost killed the flowers, been blooming freely and

quite scenting the air in its immediate vicinity with its delicious perfume. This is one of those early-flowering shrubs that are lost sight of by people when making out their lists of requirements when additions or extensions are being made. It is quite hardy, but, as the flowers are liable to be cut off by frost, as has happened in my own case, it is well worthy of a position on a well, as protection could then be afforded whenever frost appears imminent, when the blossoms are about to open, or during the flowering period.—A. W.

Outting Ivy.—The common Ivy is the best of all evergreen wall climbers, for it is at its best during the dark, dreary days of mid-winter and gives a snug, warm look to any building that is covered with it. Like all other creepers of a strong growing nature, it needs frequent attention to keep it in order, or it will fill up water-spouts and overgrow windows if not kept in check by timely pruning. It must have at least one good cutting in every year, and I find that March is the best time for doing it, for then the season of active growth is close at hand, and the young foliage quickly develops and takes off the somewhat bare look given it by clipping. A small, sharp reaping-hook, or pair of pruning shears, is the best tool for outting it in with, and it should be cleared entirely off the wall below the gutters for at least 1 foot, or it quickly fills them up and causes an obstruction.—J. G., Gosport.

Cassia corymbosa.—An illustration and short note on this brilliant-flowered plant appeared on page 3, the latter containing cultural directions for flowering it under glass. It is, I think, not generally known that in the south-west the Cassia is one of the most valuable wall plants for open-air culture. In a garden, distant but about three miles from where I write, a large plant covers some 200 square feet of wall, and is in August so crowded with blossom as to present an almost unbroken sheet of rich gold. Its flowering season is a very protracted one, blooms often being carried as late as November or December. No protection of any kind is afforded to this specimen, which is trained on a wall facing south-west, at a height of about 300 feet above sea-level. What pruning is necessary is taken in hand in early spring. I know of several other examples that do well on open walls in South Devon and Cornwall, and amateurs residing in that favoured locality will do well to find a place on a sheltered wall for the subject of this note.—S. W. F., Kingswear, South Devon.

The illustration and accompanying notes in a recent issue should be the means of bringing to the notice of many one of the very best autumn-blooming plants. In the note referred to mention is made of the many ways in which this plant may be grown. In a garden I had charge of in Ferbeck Isle, near Wareham, it flourished on the open wall, being protected in severe weather by a mat. The best plants I ever had were in large pots, growing them in the same way as *Fuchsias*. These were 8 feet high from the pot. In summer they were placed in two recesses beside a front door. The abundance of green, Ash-like leaves and mass of yellow blooms showed off well against the red brick mansion. Being grown in pots, and not started early, short joints with abundance of bloom were formed. At Cricket St. Thomas, near Chard, this Cassia has been used with the best results for many years for covering a wall under a verandah. The plants are twenty to thirty years of age, and are grown in long, narrow, wooden boxes, standing at the foot of the wall. These cover a wall 20 feet to 30 feet long, and about 15 feet high. Every autumn and up till near on Christmas they are a mass of bloom, almost hiding the foliage. Before severe frost sets in these are removed to a cold-house and pruned close in, the same as *Fuchsias*, etc.—J. CROOK.

Staphylea colchica.—This, figured recently, is one of the prettiest spring flowering plants we have for the greenhouse or conservatory from early February onwards. This can easily be had by placing in gentle moist heat, such as an early vinery or Peach-house affords, early in the year. The flowers are white and very sweet, and remind one of a *Coccoloba* when first cut open. Given the same treatment as the *molle* in Azules, the plants may be kept in pots for several years by top-dressing and re-

potting every third or fourth year. What it requires is thorough ripening of the wood. This is done by keeping the plant under glass after flowering until frost has gone and then placing in a sunny position out-of-doors, and standing to be regarded westward and a daily syringing during very hot weather in summer. If one had a good stock of plants it would be as well to plant out one half each year in a well prepared bed, forcing the other half only, and *vice versa*. The plant is quite hardy and flowers in early summer. It can be easily rooted from young shoots taken off from plants that have made early growth in March or April, and placed in sandy soil in small pots, under a bell-glass, in an intermediate house, with or without a little bottom heat. Plants so treated have had from four to six trusses of flowers on this spring, and only put in two years since. Cuttings may also be taken later on in summer and kept close, potting off singly when rooted. Nice sized plants may be grown in 6-inch and 8-inch pots by a little feeding. This I prefer doing after the plants have passed out of flower.—J. M. B.

BIRDS.

Death of Zebra Finch (*Zitella*).—This pretty little bird appears to have died in a fit of apoplexy, due to the rupture of a blood-vessel in the substance of the brain. You say your aviary is "kept beautifully heated." It is very possible that you are keeping your birds in too high a temperature, and a dry, over-heated atmosphere would tend to bring on this trouble. The internal organs appeared to be in a perfectly healthy condition, but the body was a little too fat, which pointed to the bird having been too generally treated. Millet and Canary-seed should form the diet of these birds. Little can be done in cases of this kind, although should the osmure be of slight extent the patient may recover in a degree, but can seldom be restored to perfect health, there usually being left behind paralysis of the limbs. There was no appearance of egg-binding. In the case of your other birds avoid over-feeding and over-heating the aviary.—S. S. G.

Death of Waxbill (*Ixy*).—The little bird appeared to be in a healthy condition, with the exception of a slight congestion of the liver. Perhaps you have been feeding it too liberally, or it might have taken a chill after losing its mate. These little Waxbills are so attached to their mates that on the death of one the other seldom long survives. Millet and Canary seed should form the staple diet of these birds; both white Millet and spray Millet may be given. A little green food in the shape of Watercress, Lettuce, or Chickweed may be supplied occasionally, and the flowering stalks of Grass prove very acceptable. The comparatively big nest, which is composed of hay, fibre, and feathers, is usually built in a small bush, with sometimes be placed in a small cage hanging on the wall of the aviary, while an inverted birch broom will be made use of for this purpose in an outdoor aviary.—S. S. G.

Grey Parrot pecking out its feathers (*A Subscriber*).—The habit of feather-eating is most difficult to cure, and sometimes arises from a gross condition of the system brought about by too high feeding. It is sometimes carried to such an extent that the bird becomes quite denuded, with the exception, perhaps, of the large quills of the wings and tail. The head, of course, remains fully feathered, presenting a spectacle ludicrous in the extreme. No animal food of any kind should be given to a Parrot. Bread and milk sop is also bad, as is food of any kind containing grease, egg, or milk. The habit may sometimes be cured by supplying the bird with something upon which to exercise its beak, and nothing is better for this purpose than a small piece of soft non-splintering wood. Feed your Parrot upon boiled Maize, Hemp seed, Canary seed, crusts of bread, and occasionally a little ripe fruit and a few Nuts. Do not fail to supply a good allowance of coarse grit-sand to aid digestion. The presence of insect pests will often cause feather-eating. In this case the cage should be scalded with boiling water, and, after being well dried, thoroughly painted all over with Fir-tree-oil.—S. S. G.

Canary ailing (*A Constant Reader of "Gardening"*).—You do not give any particulars as to feeding and general treatment. Your Canary appears to be suffering from a slight cold, which in some cases is the forerunner of asthma. You had better protect it from cold air, especially at night-time, by covering the cage, and avoid draughts. Many good birds are lost through their cages being placed at a window, each a position being inseparable from draughts. Discontinue Rape-seed for a time, giving in its place a liberal supply of Flax-seed. Give also occasionally a little Arrowroot-biscuit and hard-boiled yolk of eggs minced fine, also a few drops of cod-liver-oil, added to a little stale bread which has been soaked in cold water and well squeezed. A small supply of broken grit would benefit your bird, and for green food give it Watercress and Dandelion. Some old mortar, broken and mixed with the grit-seed, will also prove of value in restoring your Canary to health; but avoid pampering it with sugar or other sweet food. If there is any coughing or sneezing, an infusion of the leaves of the common Speedwell, with a little honey added, will make a tea that will prove beneficial if given daily for a week or ten days.—S. S. G.

POULTRY.

Hens ailing (*W. D. K.*).—Your hens appear to be suffering from liver disease, which may be brought about by too high feeding or from being kept in a closely-confined space. The first appearance of this complaint is generally a wasting away of the flesh, drooping comb, and unhealthy-looking droppings. The appetite varies, but there is always a great desire for water. Avoid all stimulating or heating kinds of food; care in feeding and housing will often do much where the attack is slight. As your run has been occupied by a number of fowls for some time past it would be well to remove about a foot of the soil and make up with good sweet earth or sandy gravel. Keep the sickly birds apart from the others, and give them a slight purge in the form of one grain of calomel per bird every other day for a week or ten days, mixed in the soft food. For a time lessen the quantity of food at each meal, that the digestive organs may be enabled to recover their strength. After the course of medicine has been gone through add some sulphate of iron to the drinking-water to give strength and stamina.—S. S. G.

LAW AND CUSTOM.

A gardener's notice—I am a head gardener at 21 a week salary, paid fortnightly, with cottage found. Can I leave on a fortnight's notice? There was no agreement as to notice when I was engaged.—R. T. H.

[It is a little doubtful what notice you must give, but it need not be a fortnight's. If the engagement at a weekly wage was the only matter from which any indication could be drawn, I think a week's notice would be sufficient; but as you say you are a head-gardener and have a cottage found, I think a longer notice implied, and I advise you to give a month's notice.—K. C. T.]

Removal of fixtures after expiration of tenancy.—Notice was served upon the monthly tenant of a house and piece of land to determine his tenancy, but he did not give up possession until two weeks after the expiration of the notice. When he quitted he left a wooden erection upon the land, and neither made nor suggested any arrangement for its future removal. Can the landlord detain the wooden erection until his claim for dilapidations is paid?—READER.

[Your statement reads as though this erection were affixed to the freehold, so as in point of fact to be a tenants' fixture. In the case of an ordinary tenancy, such as this appears to be, a tenant who quits, and leaves behind him any fixtures, cannot afterwards re-enter to remove such fixtures; these become the property of the landlord. If however the things left behind are mere chattels, these do not become the property of the landlord; but if the tenant re-enters to remove them he is guilty of trespass, and is liable to an action to recover damages. So the landlord, in this case, may detain the erection referred to until the tenant offers satisfactory terms.—K. C. T.]

As many of the most interesting notes and articles in "GARDENING" from the very beginning have come from its readers, we offer each week a copy of the latest edition of either "STOVE AND GREENHOUSE PLANTS," or "THE ENGLISH FLOWER GARDEN," to the sender of the most useful or interesting letter or short-article published in the current week's issue, which will be marked by us.

GARDEN WORK.

Conservatory.—There are flowers for each season, and to make the house really interesting advantage should be taken of each family as its season comes round. We are approaching now the Pelargonium season. Our earliest plants are just expanding their blossoms, and for a month or more there will be a grand show. Then will come Hydrangeas, Fuchsias, and the later Lilies, anatum and lancifolium. We generally have Trompet Lilies at Easter, and if grown in quantity they will come in succession for some time, and if cold storage is used there is hardly any limit to the time. At the present moment there are Deutzias, Spiraeas, Lily of the Valley, Roses, Tree-Cercoarias, and hulhs in much variety. Gladioli, both The Bride and the early-flowering varieties of goudavensis, may be had in bloom in March and April if potted in autumn and brought on quickly, plunged in a bed of leaves in a pit. We used to force these largely for the conservatory and for cutting at one time, but no one sticks to the same flowers always, and so a change is made and something else is taken in hand. The Dutch Roman Hyacinths are very useful now; the flowers have long stalks and are useful for cutting. We grow them four bulbs in each 5 inch pot for room decoration, but for the conservatory larger pots are used and the flowers are neatly staked up. A dozen large pots or ac mixed with Ferns are a very effective group. The Clematises form another family which, when well done, are sure to attract attention, and they are very suitable for the unheated conservatory, and they may either be planted out and trained round the sides of the house or grown in pots and trained round wires or stakes in the cool-house a special feature might be made of Canterbury Bells and Forget-me-nots, Tree-Paonies and Rhododendrons. Whatever is grown should be done well, and there should be no crowding, in an injurious sense. I remember the first plant I received of Weigela rosea; it was treated as a greenhouse plant, made a fine specimen, and attracted a good deal of attention. Now it has become a fairly hardy shrub it is not much seen under glass, yet it is one of the best forcing shrubs, and when well grown makes a fine specimen.

Stove.—Plants in flower, delicate Ferns, and fine-foliaged plants must have a thin shade when the sun is bright in the middle of the day, but we must guard against darkening the house excessively, as that weakens the growth and makes it spindling. Cuttings of winter-flowering Begonias will, if kept close, strike now in bottom-heat. Most of the Begonias will root from leaves taken off with the stalk, and the latter inserted in light sandy soil, or they will root in moist, warm Cocoa-nut-fibre. This material is a good rooting medium for cuttings of all kinds, especially Dracenas, Crotons, and other fine-leaved plants. Cuttings of Tea and other Roses taken from forced plants will root with certainty in a very short time. It is the water-pot which kills most of the cuttings which die, but the Cocoa-nut-fibre, when moistened, retains its moisture, and beyond a light dewing over, cuttings require scarcely any water till rooted and ready for potting, which should be done as soon as roots are formed. Anything which requires repotting should have attention now. The compost for fine-foliaged plants should be of a fibrous character. For the most part they want liberal supplies of water, and unless the drainage is free and the compost very fibrous the plants will not do so well. Night temperature now 65 degs. to 70 degs., but, if possible, the stove should have a division across, with one end a little warmer than the other, and then Ixores and other things which require a high temperature may have the conditions made suitable.

Ferns under glass.—Ferns are never more interesting than they are now, when making growth freely. Many of the Adiantums have lovely tints when making new growth at this season. This, or a little earlier, is the best time for dividing plants which cannot be relied upon to produce perfect spores, such as Adiantum Farleyense. Most of the Aspleniums, being viviparous, can be propagated from the little plants which form on the fronds. These little bits, taken off when small and dibbled into boxes of light sandy soil, will soon get

strong enough to transfer to small pots singly. To make rapid growth young stuff at this season must have warmth. Later on in summer I have had them do well in cold-pits, the lights being sprinkled over with limewash through the syringes. Spores may be sown now, and old Maiden-hairs and other plants divided if more stock is required; but, as a rule, seedlings make better plants than divided pieces, though they are rather looser about it. We find 60 degs. at night high enough for all Ferns in winter. Shade will soon have to be used, especially if there are Palms in the house, as Palms suffer more from hot sunshine than Ferns do. Both will require a thin shade now when the sun is bright about 10 o'clock in the forenoon.

Tomatoes under glass.—Tomatoes will bear a good deal of warmth, but it is not wise to exceed 60 degs. at night and 55 degs. will be better, as a close, stuffy atmosphere is very likely to bring on disease. On bright days give air early in the morning very freely, and do the forcing by closing early in the afternoon with the sunshine inside, and keep down fires during the day. Plants intended for outside should be grown cool to get them strong.

Window gardening.—Now is the time to put in cuttings and sow seeds. Any plants which require repotting should have attention. Aspidistras may be divided now if required. Do not over-pot nor yet over-water after repotting.

Outdoor garden.—The Grass is growing freely now, and will soon require mowing. If the roller has been used sufficiently during winter the turf will be firm and close. Woodashes are a good dressing for a lawn, and we have seen considerable improvement follow the use of basic slag; but if the lawn is thin and poor, 4 lb. of nitrate of soda now will be an advantage. Keep the mowing-machine cutters well up, so that the roots of the Grasses may be protected. The wearing out of lawns may in many cases be traced to the use of a low-set machine. This may be remedied in half an hour by dropping the front rollers half an inch. Monthrelias are lovely things on a sunny border, but they must not be left in a crowded condition or the flowers will be small, though liquid manure will help them as soon as the flower-spikes appear. It is rather late now to transplant. Tea Roses may be planted in beds or borders. They look best on slightly raised beds where the soil has been deepened and prepared. It is not so much a question of manure as rich, healthy soil, where the manure has become absorbed. A little fine rich stuff round the roots in planting is a great help, but keep the manure away from them. I have moved Tea Roses in April, after growth had begun, and found them do well. All Roses may be pruned now. Of course the recently planted Roses and Teas will be left till last.

Fruit garden.—Where Strawberries are well manured with manure, the work for the time being is pretty well done. If weeds appear they must, of course, be pulled out, and if the system of taking runners only for young plants is adopted, the fruiting plants may be kept free from runners. It means a little more work, but I think it pays. Those who have grafting to do will find the sap flowing freely now, and not delay giving attention to it. The main points in successful grafting are in selecting a time when the sap is moving upwards freely, and in fitting the scion properly to the stock. The latter is easily managed by a little practice, and that practice may take place upon the branches of any kind of tree. This is the best season for transplanting Figs, which are grown through deep rooting. The roots must be kept out of the cold, damp soil if the trees are to produce fruit. There are several ways of doing this. We once made a foundation of clinkers from the boiler fires, and grouted them in with lime and ashes to make a firm, dry bed, and the trees afterwards bore splendidly. All pruning ought to be finished now. Even the Morallo Cherries on the north walls are bursting their buds. On the whole the prospects of a good bloom on fruit-trees are favourable.

Vegetable garden.—French Beans, from their liability to red-spider, will be dangerous in fruit-houses now. They ought to be coming on in pits now, where there is some warmth either from a bed of fermenting materials or hot

PLANTS AND FLOWERS.

SOME NOTES ON EVENING PRIMROSES.

Few plants are more desirable for the hardy flower border than many of the various species of Evening Primroses. They are admirable subjects for filling many a gap, for adding a bright splash of yellow or patch of white just where the colours are wanted, and some can be usefully employed for covering the ground in the front of the border, where they may be associated with Nasturtiums or low-growing rock plants. Most of these species are perennial in duration, but (*E. biennis*, or its well-known garden variety *Lamarckiana*, is only biennial. This tall, somewhat coarse plant is of too rank a growth for the more select parts of the garden. It is more a plant for the wilder spots in large gardens, where it may be associated with Foxgloves, Verbasiums, and Cow Parsley with advantage, but for small gardens where tidiness is essential and space a consideration it is somewhat too rampant in its growth and seeds itself everywhere.

The perennial species of (*E. nocturna*, on the other hand, may be most appropriately placed among the choicest of hardy plants. Their culture for the most part is of the simplest, and their hardiness beyond dispute, but there seems to be some confusion as to their nomenclature. In the first instance we come to a group of five varieties which appear from their similarity of habit and inflorescence to belong to one species. They are (*E. frutescens*, *E. Fraseri*, *E. venusta*, *E. Youngi*, and *E. Youngi* plants. I am personally acquainted with all these varieties. I have seen *Fraseri*, *venusta*, and *Youngi* placed under the heading of *frutescens* as the name of the species. I have also heard of (*E. glauca* as being the type. But whatever may be the origin of these varieties, I am convinced that owing to their similarity it will be quite sufficient if two only are cultivated, and of the two I would choose *Youngi* and *Fraseri*. The former is a most graceful and elegant plant when properly staked and tied in order to exhibit its pretty branching habit to the best advantage. This tying and staking should be so performed as to give sufficient play to the various stems, and at the same time to provide the adequate support. Many gardeners tie up hardy plants as if they were tying a bundle of corn, and this should never be done with

E. Youngi. The time of flowering of this (*E. nocturna* commences at the end of June and continues till the middle of July, when it is loaded with numerous small flowers of the brightest yellow, and while in flower it constitutes one of the gayest objects in the border.

E. Fraseri is very similar to *Youngi*. The flower-stems are straighter in growth, somewhat taller, and the flowers, which appear practically simultaneously with those of *Youngi*, are a shade lighter in the yellow and somewhat larger and more widely expanded. Both these (*E. nocturna* may be propagated by division either in spring or autumn. In

E. speciosa we should be quite

distinct species. The flowers are white with a yellow centre, and measure about 3 inches in diameter. When the flower stems have grown about 2 feet high at the end of June or the beginning of July, the lowest bud on each stem opens and remains open for about thirty-six hours, so that one bud opening every evening there are always two flowers in bloom on a stem at a time. By far the best way of propagating (*E. nocturna speciosa* is by means of the suckers thrown up from the roots in the autumn, which can be removed in the spring just as they begin to grow, potted until the little plant has well established itself, and then about six weeks after potting turned out of the pot into permanent quarters in the open border. A plant two years old from such a sucker is at its best, and as old plants do not move satisfactorily, owing to the difficulty of arranging their long, straggling network of roots, it is better to continually raise fresh plants from suckers after the manner described.

E. MACROCARPA (the large fruited (*E. nocturna*) is an important front border plant. It has large yellow flowers, about 4 inches in diameter, which are produced from the axils of the leaves. These flowers resemble somewhat closely the flowers of *E. Lamarckiana*, and being of so large a size, present a very striking appearance at sunset in summer, when they appear close to the ground, among the dark green foliage of the plant, which rambles loosely over the soil. This (*E. nocturna* is so easily raised from seed that it is scarcely worth while to trouble about cuttings. The seed should be sown in pans or boxes, and the seedlings pricked out when large enough. I have noticed that this (*E. nocturna* harmonises pleasantly with *Nasturtiums*, more especially with the dwarf dark red *Tom Thumb Nasturtium* with dark green foliage. (*E. nocturna macrocarpa* has a very long flowering season, commencing to bloom in July and continuing to flower till overtaken by the autumn frosts. It is a plant which I should never like to be without. *Missouriensis* is a synonym. With

E. MARGINATA and *LINEARIS* we come to the end of the list of the perennial (*E. nocturna*, but both of these species should most certainly be cultivated. *Linearis*, or *riparia*, as it is also called, is a low growing (*E. nocturna* with small yellow flowers, an excellent "front-border" plant. *Marginata*, also called *eximia* or *crispifolia*, is another trailing (*E. nocturna*, producing large white flowers about 4 inches across. It has also convenient suckers for the purposes of propagation, which appear above ground in autumn. It is the only perennial (*E. nocturna* for which slugs exhibit any partiality.

E. TARANIFOLIA, also called *oculis*, is a trailing (*E. nocturna* of biennial duration. It produces flowers something after the manner of *macrocarpa*, but these flowers are, on first opening, of a beautiful pure white, changing, on fading, to a soft pink. When well developed, on a moist, warm July evening they are of an immense size, sometimes about 5 inches in diameter, and they are visible on the darkest nights, which we get at the time when they are blooming at their best. This plant must, of course, be raised from seed and will flower well the first

year if the seed is sown in March in a cold frame. Of the annual (*E. nocturna*,

E. DRUMMONDI is the best. It produces large yellow flowers like those of *Lamarckiana*, and grows about 2 feet high. Personally I find it best to treat this annual as I treat many other hardy annuals—namely, to sow it in the first instance in boxes, and then prick it out like a half-hardy annual, planting finally in the open border, leaving each plant a space of about 18 inches in diameter in which to develop. I confess that this is not absolutely necessary, but I find that many hardy annuals give the best results if so treated.

Sum.—I have left the question of the soil in which (*E. nocturna* grow best to the end, because they seem to be extremely accommodating in this respect. One is generally told that a sandy soil and full sunshine give the best results. Certainly I have found that on my soil, which is a strong loam on a very retentive subsoil, they do extremely well, and further that half shade is by no means disadvantageous in hot weather, when the plants which are fully exposed are producing small flowers and looking very limp. R. C. REYNOLDS NEVILLE.
Graft Coppy, Ramstead Lane, Chichester.

NOTES AND REPLIES.

Flowers for fragrance.—Two annuals that may be sown out-of-doors forthwith are common enough, but cannot be left out of a garden if fragrance is wanted. They are *Mignonette* and *Matthiola bicornis* (the Night-scented Stock). For flower borders both should be sown thinly. The *Matthiola* is not much to look at in the daytime; but at sunset, when its scented flowers open, we forget it has any drawbacks. To get good plants of *Mignonette*, sturdy growth must be encouraged from the outset, and this can only be effected where the seed is sown very thinly.—LEAFHURST.

Carnation Grenadin—All who require choice flowers for cutting in June should grow both the red and the white forms of this *Carnation*. It flowers a month earlier than the ordinary *Border Carnations*, and is invaluable for button-holes, bouquets, and dinner table decoration. The flowers, which are produced in great profusion, are of fine form and deliciously fragrant. It should be treated as an annual, as it makes little or no grass and cannot be propagated by cuttings. The seed should be sown in April, or where no artificial heat can be given in a sunny greenhouse or even a frame in May. If sown in April a temperature of 60° legs. should be afforded, and the seed-pan placed in a shady position. It should also be covered with a pane of glass and a little Moss laid on the glass. Water carefully, and as soon as the seedlings have made two pairs of leaves prick them out 3 inches apart into boxes containing fairly fine loamy and leafy soil. Place them near the glass and shade lightly from hot sun, and as soon as the roots have taken hold of the fresh soil remove the plants to a frame facing south and gradually harden them off. Plant them out in beds or borders—the former for preference—in June in soil containing a large percentage of leaf-mould and wood-ashes. When

planted in mixed flower borders a little of the old soil should be removed and replaced with fresh. I usually plant in pairs. Plant firmly, mulch with old Mushroom-bed or hotbed-mannure, and give a good watering.—CRAMER

COTTAGE GARDEN LESSONS.

THE first illustration in the last edition of "The English Flower Garden" is that of a Devonshire cottage garden, of which the author writes that it is "an artistic garden in its simplest expression." Farther on in the same work we are told that "among the things made by man, nothing is prettier than an English cottage garden," and that "one lesson of these little gardens that are so pretty is that one can get good effects from simple materials." Rigid economy has to be practised by the cottager. No galvanised iron arches, cemented paths, glazed tile edgings and such-like are possible for him. Any alterations and improvements that are contemplated by the occupier of the little plot must necessarily be carried out with the smallest possible expenditure and with such materials as are at hand. A couple of naturally curved or angled Oak boughs from the neighbouring wood, if firmly sunk 2 feet or so into the ground on either side of the narrow

unrivalled as secure retreats for the rapacious multitude of slugs and snails that nightly emerge from their shelter to devastate the garden. In the matter of paths, again, the cottager is restricted by considerations of expense. Carefully-laid and geometrically-arranged tiles and flagstones set in cement are not for him, but a path in front of the cottage porch that will not become sodden in wet weather is a desideratum, and this can be provided in a cheap and homely manner that effectually answers the purpose. Where pebbles are plentiful these are sometimes collected, set on their edges closely together, and rammed firmly into the path, when they form a surface very similar to the cobbled roadways so often met with in country towns and elsewhere, dry to the foot indeed, but somewhat rugged and uneven. A better way is shown in the accompanying illustration, and one that is worthy of being followed in gardens other than those of cottages. Flat stones such as are here seen are easily procurable in most neighbourhoods. These, when obtained, have their edges roughly trimmed with a hammer, and are then fitted together on the path after the fashion of a child's puzzle. When this is done they are firmly basted into the ground with a rammer or beetle, and then form a dry and fairly level

history was, to a large extent, responsible for its straggling and unsatisfactory habit of growth, but that idea has long since been dispelled. What is still more unsatisfactory is the fact that its constitution is almost played out. Of a nice collection of plants which flowered beautifully with me last season, not one of the old stools is alive to-day, although several other varieties in precisely the same position are now growing vigorously, and flower-buds already forming. As I value this plant for hybridising, however, a fair number of cuttings inserted in August last are now doing well. These cuttings were inserted in the open, and left without any covering whatever throughout the autumn and winter. This system of culture is a severe test of the hardiness of the plants perpetuated in this way, and is also the means of giving a more robust character to plants which were previously coddled in frames. The plants in the early spring may not be an interesting to look upon, but each one may be lifted with a goodly supply of roots, and many shoots in embryo just beneath the surface-soil. From plants raised in this way and planted direct from the cutting-bed to their flowering quarters, beautiful tints subsequently and quickly develop. A J. Rowberry has in recent years been crossed with many other plants possessing a good habit of growth, and the resulting progeny has been a distinct improvement.—D. B. CRANE.

Plants for small front garden.—I have a small front garden about 14 feet square which faces the west, therefore it only gets the afternoon sun. What kind of flowering plants would you recommend me to plant that would bloom this summer and look well? When and how should I plant them? I am particularly fond of a good Rose, but am afraid that in such a position Roses would not bloom.—E. E. L.

[We regard a western exposure, in so far as summer-flowering plants are concerned, as a very good one, and for so small a space no plant equals Tuberosa Begonias, for these begin flowering at midsummer and continue till cut down by frost. You can now obtain the tubers of these in the dry state, and with the ground well prepared by deep digging and the addition of some manure, plant the tubers 1 inch deep, covering each one with sand. The middle of April will be quite soon enough to plant, and if good roots are secured 9 inches or 12 inches apart will do quite well. When the Begonias are planted sow a few seeds of Mignonette over the bed to flower first and be pulled out when the Begonias require the room. It is too late to plant a Rose now, but you may plant one in autumn and it should do quite well.]

Eremuri from seed.—I was much interested in your account of *Eremurus robustus* grown from seed, which appeared in a recent issue. I have been a regular reader of GARDENING ILLUSTRATED for the last ten years. I mark each week the thing which most interests me, then lend the week's number to anyone in the village who cares to read it, and I am pleased to say there are many. At the end of the year the numbers are bound, and I find them very interesting for reference as to success or failure in anything I have tried. I am wandering away, I find, from *Eremuri*, on which I would like to give you my experience. In the autumn of 1901 I bought three rather expensive, but fine roots of *Eremurus robustus*, and planted them in good soil on a west border, mulching them with light, strawy manure in winter, and keeping the sun off them in spring on frosty mornings. All three looked very healthy, and one had a fine head of bloom. When the bloom was partly over I cut off the top half and ripened the remainder of the seed, which I sowed in sand and leaf-mould on Sept. 20, 1901. Nothing appeared, so I put an extra thick coat of partially rotted leaf-mould, covered with a piece of wire to keep the blackbirds from scratching it away, and to my joy on March 13 of this year dozens of tiny plants appeared. I shall now treat them as advised in your article, but I must say that eight years before blooming is rather a long time to look forward. However, unless one has a very long purse, this is the only way to procure a large number of beautiful and expensive plants, and also by far the most interesting.—G. M. SANDARS, Lincoln.

Passiflora corallina.—I have one of the above planted outside. It is three years old, and has not flowered yet. Please say when it should be pruned, and to what extent to encourage flowering this year? It covers half the front of the house.—H. B. SWINERT.

[If your *Passiflora* is in a sunny spot, it

A cottage garden front. From a photograph by W. Rossiter, Bath.

path, and securely lashed together at the top, will form a lasting archway over which a climbing Rose or creeper may be trained. For the verge of the path rough stones of irregular shape are sunk half their depth in the ground. No money or ingenuity can provide a more artistic and satisfactory edging than this of rough stone for any garden, however large or small. It has no formality of outline, such as is so painfully apparent in all other edgings, even when newly set in position, for each stone has its own individual form and character, while there is no site so admirably adapted to the successful culture of such plants as Saxifrageae, Sedums, members of the Dianthus family, Arabis, Aubrietia, Alyssum, dwarf Phloxes, and numerous other genera of rock plants of lowly growth, as that provided by a rough stone edging, with the many deep and narrow crannies it affords for the roots to penetrate. As the several subjects grow they spread a veil of flower and foliage over the stones, here invading the path a trifle, here separating to allow the many-angled top of rough stone to stand out from their abundant leafage and blossom, and presenting a delightful picture of varied form and colour to the eye. Margins of glazed tiles are an abomination until they are hidden from sight by living growth, and Box edgings are still worse, for nothing can ever break the stiff and formal lines that at once offend the artistic eye, while they stand

pathway. One attraction of such paths is the facility they afford for the introduction of dwarf plants into the interstices between the stones. Mossy Saxifrageae, creeping Sedums, *Erinus alpinus*, and many other little plants will edge the stones with low cushions of green, and even annuals will spangle the path with flower. I remember once seeing in such a pathway many plants of blue *Lobelia*, sprung from wind-blown seed, flowering at a height of about 2 inches, and making a bright tracery on the white stones.

S. W. F.

Spring gardening.—One of my prettiest spring borders here is made solely of Giant Polyanthus. I bought the seed originally, but picked out the very best and most free-flowering plants and divided them up. The colours are dark yellow, pale, and white, and as I keep these plants for seed, and as far apart as possible, they come pretty true. The seed is sown immediately it is ripe, comes up readily, and in spring the seedlings are transplanted into beds in some shady corner, and in autumn, when the bedding-out plants are past, the ground is manured and the Polyanthuses planted. Seedlings are by far the best.—CAUTION.

Tafted Pansy A. J. Rowberry.—The criticisms passed upon the habit of this plant during the year after its distribution have since been amply justified. It was generally acknowledged that excessive propagation in its early

should have flowered before this time. Pruning may be carried out at once by cutting away any weak and entangled shoots, leaving the principal ones regularly distributed over the front of the house in order to present a uniform appearance as the summer growth takes place. The finest effect is produced and the greatest display of blossoms obtained when the principal branches are secured in position and the minor ones allowed to dispose themselves in a loose and informal manner.]

Poor lawns (M. E. T.)—It is very evident that your lawn No. 1 has very poor, hungry sub-soil, and it will prove but a very temporary advantage to you to pare off the present bad Grass and sow it without manuring the ground. If, after paring off the Grass and weeds, you could top-dress with well-decayed manure, fork it in several inches deep, then have the ground evenly trodden all over, well levelled with the aid of a coarse rake, and then sown with good pasture Grass suitable for your sandy soil, you might then get a good permanent lawn. If you cannot give a dressing of animal manure, then get and dress the ground before forking it up with some basic slag, at the rate of 6 lb. per rod. If you add a heavy dressing of root, so much the better. Ask your seedsmen for Grasses suitable to your soil. Sow so soon as the ground is ready; well rake it, and well roll it. Keep off birds for a few days until growth takes place. That should be in about 10 days. So soon as the Grass is 3 inches in height top-dress with sulphate of ammonia, crushed fine, at the rate of 3 lb. per rod; that will soon wash in and give the Grass a good start. In six weeks it should be ready for mowing. That at the first should be done with a scythe, but later use the lawn mower. To lawn No. 2 give at once a dressing of basic slag at the rate of 4 lb. per rod. That becomes soluble slowly, and is best applied earlier. However, apply it now, and then in May give a dressing of sulphate of ammonia, same as advised above. No doubt a top-dressing of fine sifted soil at once strewn over the lawn would help it. Still, in this case, also, it is evident the soil is poor and needs feeding.

EREMURUS.

AMONG the many introductions of late years to our hardy plants few can surpass the lovely Eremurus, and the moderate price at which some of the species are now quoted should prevent none from adding a few at least to their collections. There are three species which I would strongly recommend—viz., *E. robustus*, *himalaicus*, and *Bungei*. *E. robustus* is the tallest and most handsome. The flower-stems in the accompanying photograph were nearly 9 feet high, 4 feet being covered with delicate flesh-coloured blossoms, producing a charming effect and a stately grandeur unequalled. *E. himalaicus* has white flowers, which are very handsome, but it does not grow so tall. It is, however, easy to grow, its only fault being its liability to be damaged by late frosts, as it is the first to push up its strong but tender growth. I shall never forget my first sight of a large group of *Bungei*—the effect of a large number of spikes of brilliant gold, with a dark Yew hedge as a background, was superb. This species is later in flowering—viz., July, and is altogether smaller than the preceding, attaining a height of not more than 3 feet to 4 feet. The spikes are of a beautiful chrome-yellow, with long deep orange stamens; but what adds so much to its beauty is the peculiar effect produced by the withering of the flowers: they assume a pale-brown, which quickly darkens in colour until almost a black basis formed, which, shading from the upper part

of the flower, still a bright yellow, creates a most striking effect. There is nothing to be afraid of in their

CULTURE.—Strong roots planted in autumn in an ordinary deep border with good soil, containing plenty of manure and well drained, will flower the following summer. In planting great care is necessary, as the big fleshy roots, resembling a large turnip, are very brittle. Underneath the crown I put some clean sand and a handful of charcoal, covering the roots with soil, so that the tip of the crown is just visible. In a sunny position they quickly increase, doubling their crowns each season. Plants with three crowns last season have six now. These, if carefully lifted in the autumn, can easily be divided, and if replanted as described take no harm, and flower the following summer. The only precaution necessary is protection against slugs and early spring frosts.

Eremurus robustus. From a photograph sent by Mr. Ernest Ballant, The Court, Colwell, Malvern.

This is effected by covering the crowns with cool-ashes and a little soot in autumn and some slight protection when early spring frosts are feared. I find an old champagne bottle straw envelope most suitable and effective. In case of long, severe frosts some covering is advisable, and if these small matters have attention the trouble will be amply repaid. There are many other species. E. B.

The Court, Colwell, near Malvern.

Photographs of Gardens, Plants, or Trees.—We offer each week a copy of the latest edition of the "English Flower Garden" for the best photograph of a garden or any of its contents, indoors or outdoors, sent to us in any one week. Second prize Half a Guinea.

The Prize Winners this week are: 1, Mrs. F. Hughes, Dalchoolin, Craigovan, Co. Down, for *Michasmas* *Discois* in a vase; 2, Mrs. Deane, Fairfields, Fareham, Hants, for *Opuntia Mammula* on brick pillars.

ROOM AND WINDOW.

FERNS IN AND FOR THE HOUSE.

SOME Ferns are much better adapted to this purpose than others. If the tenderer ones are so used, it is not because those which are hardier are not plentiful enough, for in most cases the latter are more easily grown, and can also be bought more cheaply. Nor can it be said that the hardier ones are less beautiful on the whole than their more delicate relations. Oftentimes it is not, however, the plants themselves that are at fault, but rather the treatment which has been accorded them. For instance, if they have been grown on rapidly in too much heat and moisture it must not cause any surprise if they do not fail to give that amount of satisfaction which might otherwise be expected from them. Ferns are frequently allotted positions where even *Geraniums* would not be stood. These positions may be where too much shade exists, or where too far removed from the glass, both evils causing a weakly and attenuated growth with less substance in the fronds. These plants cannot, of course, be expected to do good service in a dry atmosphere or where the circulation of air is at times sharp and keenly perceptible. I have lately been noting the growth of some plants of *Pteris*. The greater portion of these has stood in a single line along the front of a Peash-house, the front lights of which open and are about 2½ feet in depth. Here these plants are fully exposed to the sun every day, the growth being both robust and dense, just the durable material for the purposes now under consideration, with, of course, a little hardening oil, which is not nearly enough considered, more particularly at this season of the year with the growth none too hard. The other plants are in another house and further removed from the glass; consequently more in the shade, because the roof is covered with climbers. Here the same kinds of Ferns do not thrive so well, yet some might prefer the position as the better of the two for Ferns through fear of too much sunshine in the former instance. It may answer all very well as far as appearance goes for the time being to grow Ferns in a humid atmosphere and shady house, so long as they are not required to be used in other positions not so congenial to them. Thus eventually it is the plants that have to bear the blame, or else the place in which they are placed. Another detriment to Ferns in and for the house is that of

OVERPOTTING, which is a great mistake. A good hood of fronts upon a plant with plenty of roots working through all the soil has much the better chance of resisting effectually any change. Instead of overpotting, let the work be done thoroughly well when it is done, potting firmly, at the same time using the soil of as good a quality as it can be obtained. If the work of potting is done loosely, the roots rarely take kindly to the surface soil, the result being that this becomes sour or is washed out of the pot in watering. By good soil I do not mean that which is rich or productive of a rank growth; too much peat or leaf-soil or artificial or other manures would each have this tendency, whilst leam has not. In most cases I would use a proportion of peat, one-third to two-thirds of loam with sand in addition being a good ratio. But some may say, why not employ manurial stimulants, naing as an argument in their favour that tradn growers do so? To such my reply is that the two objects in view are widely divergent. Those who grow for sale wish naturally to push along their plants as quickly as possible, and that in as presentable a condition as can be attained, but this does not represent durability afterwards. The proper place for and use of such aids to growth are when the plants have become pot-bound. Their use then is commendable, and is a means of saving the over-potting previously discouraged. Of course, plants that have filled their pots with roots take more water, but this is the very thing we like to see them do. If a plant will not take water so frequently as it should do it is a sure indication of something being wrong, the results of which will quickly follow. It surely should not be any trouble to give a little closer attention to watering in such cases. When Ferns, that are more pot-bound than usual are used in the house it is a good plan to

safeguard any contingency of injury from drought by placing a saucer under the pot; whilst if the pot stands in a vase or jardinière, some Moss around it and upon the surface is another good protection to the roots. Another assistance to Ferns at such times is that of watering them with rain-water as contrasted with that which is hard. If standing in the front of or close to a window, it is not the sunshine which will do the plants so much harm as sharp currents of air. For instance, if the window be thrown widely open, it is better to remove the plants to another part, or drop them down upon the floor for the time being. Where goes the lighting medium, there is rather more risk of injury; but the plants, if removed to a good distance from the lights, will scarcely feel the effects of it.

The following may be taken as a good selection of Ferns for the purposes under discussion. Of the Maidenhaire, *A. canestum* is still the most reliable. Of other forms of *Adiantum*, *A. pubescens*, although a very old variety, is yet one of the best. The *Aspleniums* supply several useful varieties, *A. bulbiferum*, *A. dimorphum*, *A. laxum pumilum* and *A. lucidum* being all good kinds. *Cyrtomium falcatum* is one of the hardiest. Of the *Davallias*, *D. canariensis* and *D. Mariani* are two of the best. *Loetrea patens* and *Phlebodium aureum* are both hardy Ferns. *Nephrolepis pectinata* and *N. tuberosa* are the best of this genus. The *Pteris* family provides us with several of the best for the purpose; these embrace the forms of *P. cretica* (c. *nobilis* and c. *Mayeri* being two of the finest) and of *P. serrulata* (s. *cristata* and *s. cristata compacta* being chosen); whilst *P. tremula*, with its increasing forms, deserves special notice. Of Ferns not so reliable are the many forms of *Adiantum*, more especially those with the larger pinnae, comprising chiefly the stove kinds. The *Aspleniums*, which require heat, are not reliable, nor are the same, on the whole, of the *Davallias*. The *Lomarias*, the *Gymnogrammas*, most of the *Nephrolepis* and the hothouse forms of the *Pteris* family will not withstand adverse treatment so well as many other kinds. F.

ROSES.

SEASONABLE NOTES.

Now is a very busy time for the Rose grower. If he has any weakly plants there will be a desire to make up the gaps. It will never pay anyone to nurse up weak Rose plants when good specimens may be procured so cheaply. I do not care for the plan of just digging out a hole where there is a failure, and inserting a new plant in the position; but one cannot replant the whole bed at this time of year, so that this mending up becomes necessary. The evil may be lessened by taking out two or three shovelfuls of the soil, placing some well-decayed manure in the bottom, then returning part of the soil so that the fresh manure does not come into immediate contact with the roots. The removal of more soil than is really necessary will assist the water to pass away freely. It is the stagnation which follows heavy rains that is so injurious to Roses planted among permanent plants.

TEA ROSES planted now succeed admirably. They should be on the Brier. Prone the growths back before planting close to where budded, leaving two or three eyes on each shoot. This pruning back of Tea Roses applies also to other tribes planted out now, save the Rambler and other very vigorous growers. These may be pruned back to half their length. I have had much success with spring planting of Tea Roses even as late as the middle of April. A very important matter is to prepare the ground previously by ridging. Let this be done before Christmas if possible. The frost and pulverize the soil so well that when the time comes to plant it is in the best possible condition, and the plants start at once to root into this congenial medium. Some well-decayed manure is spread on the ground prior to ridging, then, at planting time, each plant receives about a handful of bone-meal, which is well mixed with the soil. It is surprising the growth good, healthy plants will make by the autumn. By planting thus late a crop of blossom is obtained just when the first crop of permanent plants is waning. Where beds of Roses are pegged down,

a few dwarf standards interspersed will assist to relieve such beds. These may be planted now. If the Roses are light in colour, then let the dwarf standards be of a good red or crimson, and *vice versa*. By dwarf standards I mean such as have stems from 15 inches to 20 inches. In warm localities Tea Roses, especially the thin varieties, such as Marie Van Bloutte, Mme. Falcot, etc., open very early, sometimes too early, especially for those who exhibit. Where a north wall is available and the soil can be made good, I would advise the planting of a few of this class upon such a wall with the object of retarding the blossom. Let anyone try Wm. Allen Richardson on such a wall. The colour is rich and beautiful, provided there be good root accommodation.

DWARF STOCKS for budding should be planted at once on well-trenched land. Seedling Briars are best planted with an iron dibber, taking great care that the soil is well pushed down to the ends of the long roots. That is to say, there must be no vacuum after the plant is fastened. Manetti and Brier cuttings are best planted by making a shallow cutting along a line, then a led will hold the stock in position whilst the soil is placed on to the roots. Firm planting is very necessary, but do not attempt the work if surface is wet and sticky. Better far wait a while. I have planted in the middle of April with great success. By planting rather shallow the bud may be inserted near the roots, then if plants are wanted for potting a much better plant is obtained. Manure, where it has been on the surface since November, should be very lightly turned in. Rather than risk injury to the roots by digging too deeply among the plants I prefer to half bury the manure, then cover the manure not hurried with some fine soil which usually abounds in every garden. That from the potting shed would do. Where plantations of Roses appear to require assistance in the shape of some good fertilizer, now is the time to give a dressing of basic-slag, at the rate of about 5 cwt. to the acre. Saw this broadcast and its influence will be manifest in robust growth and dark green foliage. Tea Roses may have a dressing of coot during this month, but I should prefer the above mentioned manure.

PRUNING ROSES—So much has been written upon this subject that the novice hardly knows which advice to take. If he be an exhibitor he must prune hard, if otherwise I would counsel moderate pruning. By moderate pruning I do not mean just shortening all the shoots. The thin twiggy wood, not so stout as a straw, when laid upon Hybrid Perpetuals should be discarded. The growths, to give good flowers of this tribe, should be certainly as thick as a lead pencil, and some kinds even as much as an inch or an inch and a half in circumference. These latter growths, when well hardened, are the kind to retain. Shorten such to from 9 inches to 18 inches, according to the vigour of the variety. Only one such growth on a plant would be preferable to the thin wood alluded to above. Do not be afraid to cut right down to the ground some of the growths more than two years old. If this be done and the plants are healthy, then fine new shoots spring up for next year. Teas, Hybrid Teas, and China Roses, if they have escaped injury by frost, should be very sparingly pruned; this can be done at once. Thin out the heart of the plant, but merely remove ends of the remaining growth. That is for decorative Roses. If, however, Tea Roses are wanted for exhibition, then cut back hard to good plump eyes. No matter how hard such are pruned they will flower, unless they be what are known as climbers. Roses, such as the Austrian Briars, Blairii No. 2, Rambler Rose, the many beautiful single species, and Penzance Briars, require no pruning, save just cutting away the merest ends. If the shoots are too crowded, then one or two of the oldest may be cut clean out; in fact, it is a good plan to do this every year to encourage new basal growth. Those fine 10-foot or 12-foot growths made by Crimson Rambler last summer must be left intact, and a glorious profusion of blossom will follow, more especially if the growth is bent downward or arched over, like the Wild Rose in the hedges.

ROSE HEDGES may require overhauling. Where bare towards the base cut down a growth on each plant in order to thicken the hedge. All dead wood should be removed. Some of the strong growths instead of being cut back may

be laid in horizontally to blossom, then be removed. Do not forget to give these Roses some manure, both solid and liquid, and keep free of weeds.

ROSE CUTTINGS inserted in autumn have been almost lifted out of the ground by the frost. They should be pushed down at once, or many will fail to grow. Anyone having a warm greenhouse, and who can procure some growths that have just flowered, may strike a fine lot of cuttings at this season of the year. A box with glass cover stood on the hot-water pipes makes a fine preheating-frame. The cuttings should have good, healthy foliage attached. Insert in large 60 pots, using sandy compost with plenty of drainage. Plunge pots in some leaves and keep case close. Sprinkle foliage each morning. A bottom temperature of 60 degs., with a top one of 50 degs., will root Rose cuttings admirably. Remove the covering each morning. Shade from mid-day sun by placing a piece of newspaper on glass. When the roots are about 1/2 inch long, which they will be in about four or five weeks, pot off into thumbs or small 60's and keep in the same temperature. When roots show through the pot shift into next size and gradually harden off prior to planting out in June.

FORCED ROSES—Where Roses are being forced under glass, those showing bud should have a light sprinkling of some good artificial manure, pointing this in with a sharpened stick. Much care is needed just now regarding the application of water, or a deal of mischief will follow. Plants that were top-dressed in autumn are far ahead of others that were repotted. Roses for early forcing should be repotted at midsummer if they need it. Where the plants are grown cool, then autumn is perhaps the best time for repotting, excepting for Tea Roses. These should always be repotted after first or second flowering. Plants potted in autumn and grown outdoors may now be pruned and placed in cold pits. They will flower admirably in such pits quite a month before those outdoors. Pot-Roses grown for exhibition should be tied out at once if this has not already been done. Put a string under rim of pot, and gently draw down the branches until the most approved shape is obtained. The advantages of this tying out are manifest at foliage develops.

STOCKS BUDDED LAST SUMMER should be cut back at once to the inserted bud, excepting in the case of standard Briars. These have 3 inches or 4 inches of the Brier retained above the bud to assist in drawing up the sap. This portion of Brier is removed later on. Sticks flattened on one side should be tied on to the top of the Brier in readiness to secure the new shoot as it grows, and sticks or Bamboo-canes placed near the dwarf-budded stocks. The ground, too, should be tamped in, or thinly dug over, to admit air and sun. Do not uncover the buds on the dwarf plants just yet. I refer to such as have been earthed up.

LABELS require looking to. Half the interest of a Rose-garden is lost if there are no names. Nothing can surpass the Acme label. If fastened on the plants with wire sea that the wire does not get twisted tightly. Allow it to hang loosely, or the consequences will be serious. ROSA.

Powerfully-scented Roses—Kindly give me the names of about a dozen Rose, powerfully-scented varieties, including Teas.—T. H. R.

[The Teas must be swept from the list if you seek for "powerfully scented" kinds, for the fragrance in these is of a delicate kind, yet often most refreshing. Some of the best of fragrant Roses are La France, General Jacqueminot, Horace Verost, Jean Liabaud, Gustave Pigeaneau, Chas. Darwin, Dwyager Duches de Marlborough, Mme Gabriel Luizet (not "powerfully fragrant," but exquisitely sweet-scented), Maréchal Vaillant, Mrs. Harkness, Augustine Guinoisseau, Lamarque, Gloire de Dijon, Maréchal Niel, and Triomphe de Rennes.]

As many of the most interesting notes and articles in "GARDENING" from the very beginning have come from its readers, we offer each week a copy of the latest edition of either "STOVES and GREENHOUSE PLANTS," or "THE ENGLISH FLOWER GARDEN," to the sender of the most useful or interesting letter or short article published in the current week's issue, which will be marked thus "A."

FRUIT.

FRUIT-TREE ARCHES.

It will be acknowledged that fruit-tree arches are not very numerous, and least of all in the flower garden. How often, for instance, one observes a dividing line in the shape of a fence or hedge, with a gate to shut off, as it were, the space reserved for fruit-trees and that set apart for flowers? I am rather inclined to think, however, that in some quarters this rule is now being relaxed, for in gardens I have visited there seems to be a disposition to introduce dwarf bush fruit-trees in borders where hardy flowers are grown. A year or so since I called at a place where Peare and Apples had been trained on arches over the paths, and at the time of my visit the Worcester Pearmain and other varieties were objects of beauty, clusters of fruit vying in brightness with the gay colours of the flowers beneath. Occasionally

If, however, good Grapes are expected, the same care and attention as accorded to Vines under glass must be given. A south wall or board-fence is the best position for them, as there they receive a maximum amount of sun, which is indispensable for the production of good Grapes. The formation of the border must first be considered, and as the roots of the Vines will probably occupy it for many years, it must be prepared with no niggardly hand. Very rich soil, however, must be avoided, as it encourages too strong and sappy a growth. Good turfy fibrous loam three parts, and one part mortar or plaster refuse, charcoal in pieces the size of Walnuts, wood-ashes or burnt garden refuse, and bone-meal or horn-shavings, well mixed together, answer well. Where loam cannot be obtained good garden soil may be substituted, and rather more bones or horn-shavings added. Three feet to four feet in width, and 2½ feet deep, are suitable dimensions for the border, though when the Vines are

the wall or tie them to the trellis, as the case may be, allowing plenty of room for the wood to swell, and stop the laterals at the second leaf, and again when another leaf is formed, and allow no more growth afterwards. The main rod may be allowed to extend unchecked to the top of the wall or fence. Keep the border constantly moist, renewing the mulching if the summer is hot, and if growth is not as strong as desirable, give a good soaking with diluted liquid-manure several times during the summer. Syringe the foliage on fine afternoons with water that has been warmed by the sun—this will keep red-spider at bay and otherwise assist the Vines. In autumn, when the foliage commences to turn yellow, reduce the supply of water to the roots, but by no means allow them to get dry, or the eyes will not swell to the normal size. If the border can be covered with bracken or stable-litter to a depth of a foot in winter, so much the better.

The following January cut the Vines back to

A natural fruit tree archway in a London park. From a photograph by G. A. Champion.

old trees are left for a number of years, similar to those in our illustration, their boughs extending over the pathway like sheltering arms, quaint, perhaps, but still partaking somewhat of the picturesque. To my mind, there is a quiet beauty about old trees, which seems to deepen as the years go on, and old fruit-trees are no exception to this. Here, as is shown, we have apparently old trunks and stems, about which there is an abundance of flowers and leafage, informal but charming. One must not forget, too, that before the time of leaves the blossoming fruit-trees are always attractive.

WOODHARTWICK.

OUTDOOR GRAPE CULTURE.

Outdoor Grape culture has of late received renewed attention, and there is every probability that it will again become general. As a rule, the culture given is very indifferent, many seeming to imagine that almost any kind of soil and treatment is good enough for outdoor Vines.

planted against a dwelling this width cannot always be allowed. The border must be drained by placing 6 inches of broken bricks in the bottom, these being covered with sods, grass side downwards, to prevent the soil mixing with them. The soil should be in a semi-dry condition, as borders made of wet material soon become sour, and the Vines do not root in it freely. March is the best time for planting, but the Vines should be cut back to within a foot of their base in January. If pruned in March they will probably bleed badly. After pruning the wounds should be dressed with styptic to prevent bleeding. When planting shorten all shoe-sole-like roots and carefully spread out the rest, covering them with 3 inches or 4 inches of the finest of the compost and making it very firm, finally mulching them with short litter as a protection from frost. One, two, or three rods may be allowed to each Vine, according to the space at command, but they should not be closer together than 2½ feet.

A growth proceeds nail the leading shoots to

within 3 feet or 4 feet of the border, and remove all laterals, taking care to preserve the eyes at their base, and early in April uncover the border and give it a good watering. The Vines may be allowed to carry three or four bunches each, according to their strength. The laterals should be evenly disposed 18 inches apart on each side of the Vine-rod, the surplus ones being rubbed off when quite small. This year the main rods may be topped when they have grown 6 feet, provided they are strong, otherwise they must be allowed to grow to the top of the wall, as in the previous year. A second stopping will not be necessary. The laterals must be stopped at the second leaf beyond the bunch, and not allowed to grow any more, they must also be nailed securely to the wall. Water and syringe as advised for the first year, and apply a mulch of short manure to the border in May. Thin the bunches when the berries are the size of small shot, taking care not to leave too many berries, or they may damp off when ripening if the weather is wet. The new hardy black Grape,

Reine Olga, which received an award of merit last autumn, will probably be the most commonly grown in the future. The bunches and berries are large, the latter colouring beautifully, and being of delicious flavour. Black Cluster, Old White Sweetwater, and Miller's Burgundy are all good open-air varieties.

SUFFOLK.

NOTES AND REPLIES.

Yellow Gooseberries.—Yellow Gooseberries are very popular, owing to their attractive appearance, and they invariably realise good prices. The number of varieties has of late greatly increased, and some of the largest, when grown as cordons against sunny walls or board fences, are exceedingly handsome and of delicious flavour. By the way, the plan of growing Gooseberries as cordons is now very common, and I can strongly recommend it to amateurs. Early Sulphur is still the earliest yellow variety. It is of medium size, very juicy, and exceedingly rich and juicy, and no garden should be without a tree of it. Golden Drop is a very showy variety of good size and an abundant bearer. Champagne is a deliciously flavoured variety, a good bearer, and unsurpassed for wine. Golden Lion is another excellent variety and unsurpassed for dessert. The colour is brilliant yellow. Of the larger exhibition sorts, Leveller is perhaps the most showy, being of great size and handsome form. It is a prodigious cropper and the flavour is excellent. Drill, though an old variety, is still indispensable. It possesses a very hardy constitution and seldom fails to fruit well. Added to this the quality is first-rate. Highlander is another grand variety, and indispensable where the fruit is required for exhibition. Leader and Trampeter must also be included, their all-round qualities being all that can be desired.—J.

Fruit prospects.—As we have thus far had remarkably little sunshine, the first buds are as firmly rolled up as they were at Christmas, and from present appearance we shall have a late spring. On looking round the trees and bushes I find there is likely to be a great wealth of bloom, and if we get no exceptional frosts in May, there ought to be a good crop. As last year was generally a very prolific fruit season, many people seem to think that this year must be a poor one, but from many years' observation I do not think that this must follow. There is no doubt that when fruit-trees are allowed to carry all the fruit that sets, then the tree gets so exhausted that it takes a year or more to recover. The notion has got a firm hold that some kinds of fruit are alternate year croppers, whereas if the crop had been thinned so that the tree could have perfected its crop, and also the buds for next season's crops, there would be a crop every year. I have just examined my Apple and Pear trees, and I find that those that carried full crops last year are looking best for bloom this year. On well-managed trees there should be no lack of spare buds that only need developing into fruit-buds. Pay attention to their needs in the autumn, and even before one crop is gathered, the work of feeding the roots for the next crop should start. While the soil is warm is the time to soak the roots with manure-water to plump up the buds for next season.—JAMES OROUN, *Gosport*.

Muscad Grapes falling.—I should feel obliged if you could tell me the cause of my Grapes going like the enclosed? They are white Muscads, and for the past two years they have given very little fruit—about two bunches this year and the same last. There are about forty bunches, some the same as those enclosed. I send also two leaves to show that the Vine seems in good health. The Vine is rather old, but always cropped well till last year. These are from the young wood.—F. M. CARROVER.

Evidently your Vine roots are not healthy, and there is a suspicion of their being in ungenial quarters. You do not say whether the berries are an inside or an outside one; but the roots are the chief cause of complaint. Vines, particularly Muscads, when forced early, the roots in cold soil, and not in a healthy condition, produce bunches similar to yours. Early forcing aggravates the evil very much. The leaves sent are of a healthy colour, but they are extremely deficient of substance, pointing to debility from a weak root action. You should improve the soil conditions so as to quicken the root growth, and encourage them nearer the surface. Preparing you have given a top-dressing of turfy loam, which is necessary every winter, you would do well to apply a coat of cow-manure some 2 inches

in thickness. This has a wonderful effect on weak Vines if their roots are near enough the surface to benefit by its pressure. Give also liquid manure diluted each time water is needed. A dressing of bone-meal would do much good, particularly if the soil should be deficient of lime. Hard forcing should be stayed, and a more natural course followed at least for a season or two, so as to give the Vines an opportunity to recoup some of their lost vigour. Are you satisfied that the burler has a sufficiency of water in the summer? There are so many causes that are likely to invite debility, that, without some knowledge of the circumstances, we could not define the most likely ones. Muscads are particularly liable to give tendrilled bunches, such as those you send, when there is an absence of proper nutriment in the soil, and the growth of the Vine is weak and indifferently ripened. Remove these causes by more generous treatment, and start your Vines later—say by the 1st of March—and you may find much better returns. Old Vines are sometimes improved by cutting their rods down to the joint just below the lowermost or first wire of the rod trellis and turning up a young rod; or you might try extension by increasing the number of rods on some Vines, removing some of the existing ones to make room for the corresponding number of new rods introduced. An example such as this, with healthy roots, sometimes proves most satisfactory.]

INDOOR PLANTS

THE OLD DOUBLE WHITE PRIMULA.

In a general sense this is not an amateur's plant, though there are cases where it may be fairly well done. In the most experienced hands this plant will go wrong occasionally, though the mischief can usually be traced to careless watering. Nevertheless, when well done few plants are more serviceable to the gardener from early November up to April for supplying cut-flowers or planting in vases in the mansion, and I use them with good effect on the dinner-table. Those who have a stock of this cut-and-come-again plant should at once set about mounding them up with a mixture of finely-sifted loam and leaf-soil, chopped Sphagnum, and a good percentage of silver or river sand, first trimming off the lowermost leaves. Should there not be much space for this top-dressing it is a good plan to drop the plant into a size larger pot, so that room is left for the soil. Keep this fairly moist by sprinkling each day with a rose on the can, and from now onwards a slight shade will be necessary, and the plant can be stood in a cold-pit or frame, but within a foot of the glass, or the leaves get drawn. In about six weeks the plants should be fit to split up, taking every care of the fibre-like roots attached to the young offshoots, avoiding the centre growth of each plant, as I have found this does not grow away so kindly as the outer growths. For potting, use a similar soil as advocated above, except the Sphagnum. Pots 2½ inches to 4 inches in diameter will be large enough, not pressing the soil too firmly. Water in, and place in a frame or pit that has just a slight bottom-heat, though mine generally go straight into a cold-frame. Keep close and well shaded from the sun for a fortnight, lightly bedewing overhead with the syringe on bright mornings. As soon as growth starts afresh give a little ventilation, when, if all goes well, they should be ready to put into the pots they are expected to flower in towards the end of May. These need not exceed 5½ inches in diameter, as good decorative stuff can be grown and flowered in sizes less even than this, as will be seen by the plant I forward you.

The soil for this final potting should consist of three parts of fibrous loam to two parts of leaf-soil and finely sifted peat, a good percentage of sand, and a fair sprinkling of well broken up charcoal. Though I dislike using much manure of any kind in the soil, last season I added a 6-inch petrol of well powdered deer droppings to each bushel of soil, and the plants certainly profited by it. The plants thrive well in cold-frames during summer, carefully shading from ten o'clock up to four p.m. if the sun reaches them up to that time, and do not water indiscriminately at any time, affording plenty of air and space and keeping near to the glass. Towards the middle of October the whole batch

should be removed to a shelf in the greenhouse, when the trusses of bloom will soon push up. By the end of November the plants should be a perfect sheet of bloom, with stout flower-stems. There is supposed to be a large-flowered variety, grandiflora by name, but I consider it is more a matter of culture than ought else. When watering during winter avoid pouring it into the centre, and shield damping set in dust with powdered charcoal.

J. M. R.

[With the above notes was sent a beautifully grown plant, literally laden with blooms of fine size and substance, the foliage quite hiding the pot. This, as "J. M. R." says, is one of the most useful "cut-and-come-again" plants we have. It used to be well grown many years ago in the R.H.S. Gardens at Chiswick, the plant being increased in the way recommended by our correspondent. We remember that a batch of double varieties in various colours, raised by the late Mr. Gilbert, of Birghley, was grown at the same time, but they did not keep up the succession of bloom that the "old double white" did, and we doubt if they are now in cultivation.—Ed.]

TREATMENT OF AFRICAN BULBS.

I was much obliged by someone telling me the cultivation required for the following South African bulbs, the names of which I give: *Bulbine pugioniformis*, *Watsonia O'Brienii*, *Wachenborfia paniculata*, *Trichonema*, *Satyrium*, *Veltheimia*, and *Hypoxis stellata*.—ANN.

[*Bulbine pugioniformis* is a pretty little bulbous plant, with narrow leaves and clusters of yellow blossoms. *Watsonia O'Brienii* (according to the latest classification the correct name of this plant is *Watsonia iridifolia*) is a charming plant, a good deal like a slender-growing *Gladiolus*, with blossoms of the purest white. *Wachenborfia paniculata* bears from three to five golden-yellow flowers on a spike a foot or more in height. It usually blooms in the spring. *Trichonema* is now included in the genus *Romulea*, a pretty class of small-growing bulbs, most of which have flowers of some shade of rose or yellow. *Satyrium* is a group of terrestrial Orchids, most of which have large, fleshy leaves that lie almost flat on the soil. The different species have white, pink, or yellow blossoms. *Veltheimia* belongs to the Lily family, and consists of only two or three species. The best known is *V. viridifolia*, with deep green unimbricate leaves from 6 inches to a foot long, arranged in a vaseform manner. The flower-spike, which reaches a height of 12 inches to 18 inches, is terminated by a spike of tubular flowers, which in shape and arrangement suggest some of the *Kniphofias*, but the colour is a kind of reddish-rose. *Hypoxis stellata* forms a tuft of hairy Grass-like leaves and starry bluish-white flowers. *Hesperanthe falcata* is nearly related to the *Ixias*, with flowers brownish outside and white in the interior. We cannot find *Antholyza nervosa*, but the *Antholyza* are a good deal in the way of *Montbretias*, but bolder growing. Most of them have flowers of some shade of scarlet or yellow.

None of the above-named bulbs are hardy, but all require the temperature of a greenhouse—that is to say, during the winter a minimum of 45 degs. As your bulbs have been out of the ground for some time they should all be potted without further delay. With the exception of the *Satyrium* the same kind of soil will do for the whole of them. Equal parts of good yellow loam and well-decayed leaf-mould or peat, with half a part of sand, all well mixed together, will form a suitable compost. If the loam is of a lighter nature, less peat or leaf-mould must be used. The pots employed will, of course, depend upon the size or number of the bulbs, but in any case they must be effectually drained, and when the potting is done a little water may be given to settle the soil in its place, after which the soil should be kept slightly moist till the bulbs begin to grow, when an increased supply must be given. After the bulbs flower and show signs of going to rest, less water must, of course, be supplied, and when thoroughly dormant they should have a period of absolute rest. The *Satyrium* needs a more open soil, such as good fibrous loam and peat in equal parts, with a liberal sprinkling of sand. During the resting period they must be kept on the dry side, but not too much probed. For these the soil should be broken up into small nodules by hand.]

THE GREAT INDIAN DODDER (*CUSCUTA REFLEXA*).

All the Dodders, including four British species, are leafless, twining parasites, nearly related to the Morning Glory or Convolvulus family. The kind we now illustrate in flower as growing on a variegated form of Ivy is *C. reflexa*, or *C. verucosa*, as it is sometimes called, having been figured in Sweet's "British Flower Garden" under that name many years ago. The plant is not quite hardy, but grows most luxuriantly during the summer months in the open air on such host plants as Ivy, Jasmine, Forsythia, Zonal Pelargoniums, and *Cytisus fragrans*. All the kinds are easily raised by sowing ripe seeds in earth near to the plants on which they like to grow. The seeds send up a long, slender stem, which gyrates until it touches some succulent portion of the host plant, into which it thrusts its aerial roots, after which it severs its connection with the ground for ever, and exists as a parasite on the host plant. One of our native species—viz., *C. trifolia*—often does considerable damage to Clover crops, and it is difficult to exterminate, as its ripe seeds are often distributed along with those of the Clover plant. In Ireland, however, the seeds of the Dodder rarely ripen, and so its ravages are confined to the effects of imported seeds. *C. reflexa* is a rampant grower, covering Ivy or Forsythia bushes with a dense web of its wiry-looking growths. Its flowers are borne in dense clusters at the nodes of the stem, and are in shape not unlike those of Lily of the Valley, only smaller, and on warm and sunny days they have the odour of Aponogeton. The illustration was made from specimens grown in the College Botanical Garden at Dublin, and gives an excellent idea of the way in which it attacks the petioles and stems of Ivy in its straggling for food.

CROMER.

CENTROPOGON LUCYANUS.

This is a very showy stove-flowering plant during the winter months, and to have it fit for this purpose cuttings should now be put in. Select young flowerless shoots about 3 inches in length, with a heel if possible, and insert in 3-inch pots filled with sandy soil, and place in a close propagating-box having a bottom heat of 70 degs. to 80 degs. In about three weeks they should be ready to pot up singly into the same six pot, using loam and leaf soil, with a dash of fine peat and sand. Keep in a temperature of 60 degs. to 70 degs., and near the glass roof, and as soon as the little plants have laid hold of the soil nip out the point of the shoot, repotting when necessary, and using similar soil but more lumpy. Nice servicable stuff can be had in 5-inch pots, and the plant is at home grown in a basket, and allowed to droop naturally, as in the case of an Ivy-leaf Geranium. Grown in pots the plants require a neat stake betimes, for they make strong growths 15 inches to 18 inches in length. One-year-old plants can also be grown another season if cut fairly hard back and partly shaken out when nicely breaking into new growth and treated similar to young plants. Towards the middle of June they can be placed in cold frames, if lightly shaded during bright weather and closed about 3.30 p.m., with a good syringing, working it well underneath the foliage, as the plant is liable to be infested with thrips if grown in too dry an atmosphere. A little weak manure-water, or a pinch of some artificial manure once a week when the pots are full of roots, will keep the foliage good in colour and assist the plants to throw up strong suckers from the bottom, which should not be pinched, as these will yield good trusses of rosy-carmine flowers early in December if the plants are placed in the stove at the end of September.

J. M. B.

THE CHINESE PRIMULA (*PRIMULA SINENSIS*).

The beautiful varieties of *Primula sinensis* are favourites with everyone, and the fact of their flowering during the dullest months of the year greatly enhances their value. The seed may be sown in March, April, and May, but the earlier it is sown the larger and better the plants will be. Pans 3 inches in depth are the best receptacles for the seed, and the most suitable compost is one consisting of finely-sifted loamy soil and leaf-mould in equal quantities. Fill the pans with the soil to within $\frac{1}{2}$ inch of the top, and press it in firmly, afterwards giving a gentle watering with a can to which a fine rose has been attached. Let the pans drain for a short time, then sow the seed thinly, covering it thinly with silver-sand, and press down the surface firmly. Cover the pan with a pane of glass, and on the glass lay a little clean Moss. Place in a temperature of from 60 degs. to 65 degs., and shade from the sun till the plants are up. Water cautiously, and always with chilled water, as watering with cold water is courting failure. When the young plants are $\frac{1}{2}$ inch high pot them off into small pots, in a mixture of light, fibrous loam three parts, and one part cow-manure which has lain long enough to assume the consistency of fine mould, leaf-mould, and silver or river-sand. Press the soil firmly, but not hard, round the roots, and give a gentle watering. Place them near the glass in a temperature of 50 degs. to 55 degs., and lightly shade them during the hottest part of the day. All being well they will be ready for shifting into $4\frac{1}{2}$ -inch pots in May, when similar soil should be employed, but in a rather rougher state. Powdered fowls' or pigeons'-manure is excellent for *Primula*, but it must be used in strict moderation. I have known it mixed with very fine soil and used as a surface-dressing with very good results. At the beginning of June the plants should be placed on a layer of coarse ashes in a drip-proof frame facing south, and shaded from the sun with tiffany, or by dressing the glass with a mixture of whitening and milk. *Primulas* require more sun than many imagine, and growing them entirely in the shade is a mistake. The plants should be syringed twice daily and plenty of air given,

FUCHSIAS.

Few plants surpass Fuchsias for gracefulness and beauty, and few are more useful. They are essentially amateurs' plants, as they may be grown to perfection without the aid of artificial heat. To ensure success in their propagation, however, a little heat is necessary, and if a gentle bottom heat can be afforded, so much the better. A few old plants should be pruned and placed in a light house or pit during this month for the production of cuttings. Syringe them twice daily and keep a moist atmosphere, and when the young shoots have grown a couple of inches detach them with a heel or portion of the older wood. Insert them not too thickly in 4 inch pots in fine loamy and leafy soil and silver-sand. Water them well and cover them with a handlight or bell-glass in a temperature of 60 degs. Keep them shaded from the sun, and fairly moist till rooted, admitting a little air to handlight or bell-glass to allow of the escape of superfluous moisture. When well rooted pot them carefully into $2\frac{1}{2}$ -inch pots, using a compost of three parts good rich loam and one part well decomposed cow-manure free from worms, leaf-mould, and coarse sand or grit, well mixed. Pot firmly, and give a gentle watering with tepid water. Keep the plants in heat till established, then remove them to a sunny house and give a temperature of 50 degs. When the plants are 4 inches or 6 inches high

as the case may be. Previous to potting remove a little of the old soil from the roots and shorten large, straggling roots. Use the soil in as rough a condition as possible, and pot firmly. Afford a temperature of from 50 degs. to 52 degs. till the weather gets warm, when artificial heat may be dispensed with. Abundance of light, air, and moisture, and frequent syringings in order to ward off red-spider and thrip, are what the plants require in summer. They should also be assisted occasionally with an approved fertiliser. Where artificial heat cannot be given, the plants should be pruned and started in March, and otherwise treated as advised for earlier-started plants.

The following are a few of the freest-flowering and handsomest varieties: Beauty of Exeter, Countess of Aberdeen, Earl of Beaconsfield, Mrs. Poysine, Princess May, Gertrude Pearson, Queen. Double varieties are best

the frame being closed tolerably early in the afternoon to husband sun-heat, and a little air given at night.

The plants sometimes produce flower-trusses in summer, but these must be removed in order to strengthen the plants. Weak liquid-manure or some other approved fertiliser should be given at each alternate watering, and the plants should be potted into 6-inch, and afterwards into 8-inch, pots before they become root-bound. As the autumn approaches less shade and more air will be necessary, and the plants must be removed to a light, airy house at the beginning of October, a temperature of 50 degs. during winter being a suitable one. C.

THE CULTURE OF ANNUALS IN POTS.

WHETHER on account of the beautiful display they afford in beds and borders, or regarded in the light of the little expense annuals are, one cannot but recognise the fact that every year they are becoming more popular, and perhaps this is not surprising when one takes into consideration what quantities of blossoms they yield in a season. In this connection one thinks of blue Poppies, Sweet Peas, and Asters; but how few, comparatively, make use of annuals in pots, some, at any rate, only looking upon them as garden subjects. As we have entered upon that period of the year when the question of sowing seeds has to be faced, I wish to set before readers the value of certain annuals for pot culture, both for greenhouse and general indoor growing. At the outset, therefore, it is easy to have, at no very great outlay, a house of flowers, and to maintain such by sowing in succession. I would bring before any who have not given annuals a fair trial in pots the value of pretty things like *Rhodanthea*, seed of which may be sown at once to flower in May and June, according to the heat of the house, not that they need any great amount of warmth. One may sow the seed in shallow boxes or pans of very light soil thinly, just covering them, then prick them off into pots (5-inch or 6 inch), from fifteen to twenty in a pot, and these will give charming blossoms which last a considerable time. *R. Manglesi* has pink flowers, and *maculata alba* white. Balsams I would also strongly recommend to those who want a show of flowers at little cost; a packet of good seed may be bought for a shilling, and this will produce a quantity of plants. Balsams pay well for good culture and attention. You may get them to bloom in 3½-inch pots in ordinary soil devoid of much sustenance, but if one increases the size of the pot, say, to 6 inches or even 8 inches, and provides for them old turf, soil and leaf-mould, with a good proportion of cow-manure, and, as they grow, remove them until that sized pot is reached—for Balsams like plenty of root room—feeding them with liquid-manure, one will be able to get stout, stiff plants carrying large numbers of blossoms that will far exceed those grown in small pots and under half-starved conditions. Some people I know do not view Cockscombs with very much favour, thinking they are too set and formal, but there is something unique about them, and even if formal they have a beauty which no one can ignore who has once grown them with anything like success, and this means the raising of the seed in a brisk heat, and keeping the plants in a humid atmosphere so as to encourage growth. A 5-inch or 6-inch pot is a useful size into which to finally pot them, and as soon as the roots begin to feel the sides of the pot the combs soon commence to form. Good light loam suits them.

Nemesia would be grown more outside as well as in pots did people only realise what beautiful plants they are and how easily they may be raised. Now is the time to sow the seed indoors, and fibrous loam with a little wood-ashes is all they require in the matter of compost. An outdoor sowing may be made in May. Embracing whites and pinks, oranges, yellows, and crimson, they give a most charming appearance to a house, whilst for beds and borders few annuals can surpass them.

The *Schizanthus* is another annual that is not widely known, and it deserves to be, for cultivated in pots it provides one with innumerable frail-looking blossoms, and the habit of the plant, though straggling, is very beautiful when covered with flowers each year.

Seeds may be sown in heat now in pans of light soil.

Rightly cultivated, *Coleuses* should be treated as annuals, for it is scarcely worth the trouble of wintering when by sowing in a brisk heat in March and April one may raise sufficient plants for decoration during the summer either for the house or table. For giving a gay appearance to a greenhouse in winter what can one have half so pretty as *Cinerarias* and *Primulas*, the seed of which may be got in between now and the end of May, and it is admitted that by far the best method of dealing with them is to raise from seed the plants one requires each year. Annuals for indoors are, I submit, worth the consideration of all lovers of flowers at the present moment. W. F.

FREESIAS.

THERE are few plants that more readily repay the minimum of trouble that is necessary for their well-being by grace of form, refinement of colour, and delicacy of fragrance than do the *Freessias*. The one desideratum is that the bulbs should be well ripened. Some years ago this was not so well understood as it is to-day, and in those times there were many failures evidently attributable to that cause. When once a stock has been procured, if care be taken that the yearly ripening is adequate, little difficulty will be experienced in bringing to perfection a good show of blossom. The bulbs should be potted not later than the end of August, eight being a good number for a 5½-inch pot, and fourteen for a 6½-inch, a compost of two-thirds fibrous loam and one-third leaf-mould, with some silver-sand, being well suited to their requirements. They should then be placed in a cold-frame under 6 inches of Cocoa-nut-fibre, which must be removed as soon as the growths push through the soil, which will generally be in from two weeks to a month. In this position they should remain, air being given when possible, till the flower-spikes can be felt, when they may be brought into the greenhouse. By this system they come into bloom naturally about the middle or end of March, and are stronger and more free-flowering than when subjected to greater heat. If, however, they are required to be in bloom by the new year, forcing is imperative, but in this case the plants are rarely so ornamental as when grown under cooler conditions. As the pots become full of roots, and until the flowers are fully formed, weak liquid-manure should be given two or three times a week. When the blooms have faded the plants should still receive water until the leaves begin to show signs of turning yellow, when the pots should be placed in the hottest and sunniest position in the glass-house and kept absolutely dry. After being roasted in this manner until the end of July or beginning of August the bulbs can be turned out of the pots, the large ones being potted again for the next season's blooming and the bulbets, of which many will doubtless be found, grown on in boxes until they reach a flowering size. For supports to the stems of the pot-plants, nothing will be found better than lengths of stiff galvanised wire painted a similar colour to the leaves.

SALVIAS.

Few plants brighten up our conservatories and greenhouses more throughout the winter months than do the varieties of *Salvia*, when well grown and flowered. Now is a good time to insert cuttings of a few for earliest flowering, continuing this well into May for later batches. I prefer keeping the whole stock in pots throughout the year. Having tried the planting out system for two or three years I gave it up, finding that the growth got so broken about, even when given all the care possible when lifting and getting them into their pots. There is probably more labour required as to watering, but the returns are better. I grow some nine different varieties, all of which will soon root if placed in sandy soil in 4-inch pots, watered, and placed under a glass case in a temperature of about 60 degs. during the night. No bottom-heat is necessary, though rooting takes place sooner if a little is given. Pot off singly when fit, and give a gentle warmth up to the end of April, when a cold-frame will suffice until frost is past, when outdoor treatment as afforded the

Chrysanthemum will meet the requirements of these. Keep the points of the shoots nipped out occasionally, and the syringe plied among the plants, or red-spider will soon attack them. Shift on as the plants fill their pots with roots into sizes varying from 5½-inch up to 12-inch, according to variety, using similar soil as for the *Chrysanthemum*. Stake the plants before the wind has a chance to break them, as most of the varieties are brittle. Give them a sunny position, and as soon as the pots are full of roots, weak manure-water once a week will greatly benefit them. A piece of slate should be placed at the bottom of the pot when outdoors, so as to prevent the plant rooting through, and during the warmest days a good syringing should be given all the plants towards 6 p.m., this refreshing the plants and assisting to ward off the greatest pest to *Salvia*, red-spider. Early in October, or before frost can harm them, place the plants in a cool-house and near the glass, giving abundance of air for a few weeks until they get accustomed to the change. As the day gets some avoid too wet a condition of the soil, or the foliage will drop.

The earliest to flower is *Bethelli*, a large pink or amaranth and very showy, closely followed by the lovely hino *Pitcheri*, synonymous with *exarea grandiflora*. Unfortunately, neither of these two varieties continues in bloom long, and both are past their best by the middle of November, as a rule. Both are so lovely that one cannot afford to be without them. It should here be stated that *S. Pitcheri* must not be stopped more than twice during summer, or the recemas will be very poor. This comes away from the bottom each spring. It is also quite hardy in Devon and Cornwall. *S. splendens grandiflora*, *splendens Braanti*, *Ingenieur Clavenad*, *Glory of Stuttgart*, *rutilans*, *Heeri*, and *generosiflora* are all worthy of culture, and succeed each other in the order named as to flowering. J. M. B.

GREENHOUSE BOILERS.

TO THE EDITOR OF "GARDENING ILLUSTRATED."

SIR,—Permit me to warn your readers against the purchase of boilers for heating greenhouses with the flow and return pipes less than 3 inches in diameter, starting from the boiler itself. I speak from experience. They are bound to go wrong, and are much more expensive in the long run, as it takes double the fuel to get up the proper heat at starting. A cold boiler should get up heat in less than an hour to be considered good and efficient. Anything contracting the egress and ingress of the hot water must make it slower to heat and more difficult to keep up a fixed heat, especially in cold weather. Apart from this, there is always the possibility of furring up either with lime or rust. Rain water will, of course, obviate this to a great extent if one can get it. Once the pipes get choked there is the danger of explosion. I have two boilers and manage them myself. One is a very small upright horse-shoe, built into the end of the small hot-house, and heats about 50 feet of 4 inch piping, and the other heats 120 feet of 4-inch. For the former I find the best fuel is the house cinders passed twice through a cinder sifter. They are stored for me and the clinkers picked out. These boilers are all the better for a screen in iron put in front of them to keep them from the effects of the weather, if in the open and with no shed to protect them. My other boiler is an upright, independent, cylindrical one, and has a spigot to cover it. In the case of the little boiler, I stoke the last thing at 10 p.m., and the fire is going at 10 a.m. The heat averages 70 degs. on mild nights down to 55 degs. on very cold ones. From my cylindrical boiler I get even better results. The fuel for this is small coke. When I had it first the makers sent it out with too small a chimney pipe—namely, 4 inches, and it used to go out. The grating at the bottom was also too small, only 6 inches, so that the ashes were soon choked it. Now I have a 5 inch chimney pipe and a 12-inch grating. On some nights if the wind rose, the fire used to burn out before morning, so I had a rising feeder added. This adjunct has been such an improvement that one day this winter the fire kept alight and gave good heat for twenty-four hours without attention or stoking. I happened to be ill, and had to have a gardener to attend to it for me, and he was simply astonished. As a rule, I prefer

to attend to it at a fixed time, and do not let it run more than twelve hours without attention. It is by far the best boiler for the amateur, as there is no trouble with it. I believe it is known in the trade as the "Star Independent" boiler. Its only drawback, if it can be considered so, is that it must have a shed built over it, whereas the other one can be huilt into one end of the greenhouse. I notice the makers send the "Star" out with 2 inch pipes at the boiler, and charge 5s. extra for 4-inch connections. It is quite worth the extra for the addition. One thing I need scarcely impress on all who have to do with boilers is, that all hard-worked boilers should have the flues and fire-box cleaned out at least once a week, and the fire relighted.

C. G. V.

LACHENALIAS.

It is pleasing to find that these useful spring flowers are receiving more attention than formerly. No flower pays better for good culture, and their value is enhanced by the length of time they last when cut and placed in water. I know of no other flower that equals them in

the bulbs firmly, just covering them with soil, and leave a good margin for water. Potting completed, stand them in a frame and keep them as cool as possible, drawing the lights off on fine days, but tilting them up during heavy rains, as if the soil becomes solidened before the bulbs form new roots, failure may be apprehended. Keep them in the frame till the end of October, then remove them to a warm greenhouse, giving them a position near the glass. The cooler they are kept the finer will the flowers be. As growth advances assist it with weak liquid-manure at each alternate watering, and syringe the plants lightly on fine days till the flowers commence to expand. If wanted to flower early, the plants may be subjected to a temperature of 55 degs. or 60 degs. in January. The best varieties for pot culture are Nelsoni, pendula, Causton Gem, and Vicar of Canster.

CROMER.

NOTES AND REPLIES.

Hedychium coronarium.—I have a *Hedychium* which was given me in July, 1900. In March, 1901, I divided it and made three of it. The plants made fair growth last summer, but did not flower. In the winter I kept them cool and rather dry, and the foliage

hardy plants some of the handsomest flowers are the Peonies, but these in their flowering would certainly disappoint you if you plant them now. As much depends on your views as to what is a handsome flower, we think you had better make the case more clear by repeating the query with explanations.]

Plants with fragrant flowers and leaves.—Kindly tell me the names of twenty-four plants with sweet-scented flowers and fragrant leaves.—T. R. R.

[The scented *Pelargoniums* are far in advance of all else, and in their varied character of leaf and blossom, as well as much varied fragrance, are quite unique. Of other plants possessing fragrance are many species of *Primula*, particularly the double forms of *P. acaulis*, also *P. cashmeriana*, *P. viscoso-nivea*, and many more. The Sweet-scented *Verbena* is always a favourite, and equally so the *Violet* and *Bignonette*. The *Bergamot* (*Monarda didyma*) has beautifully fragrant leaves and showy flowers. Then there are some species of *Daphne*, as—*e.g.*, *D. indica* and its variety *rubra*, *D. mezereon*, *D. onocrum*. Some *Acacias* are pleasantly fragrant, and *Hyacintha* yield quite a host in the same way. Then, if you turn to *Liliums*, you find some of the most powerfully fragrant of all flowers; particularly may we mention *auratum*, *longifolium* var. as among the strongest, and the forms of *L. speciosum* as representing the more delicately scented kinds. Other plants are *Jasmines*, *Gardenias*, *Fre-sias*, *Himes* *slagans*, and, of course, many *Pinks* and *Carnations*.]

Bulb-growing without soil and water.—In your issue of March 22 I see that in "Short Replies" "Arum" asks about a Lily, which you say cannot be grown without soil or water. I know for a fact, having seen the bulb in process of growing, that such a plant exists, but, unfortunately, do not know its name. All that is necessary is to place the bulb in a dry saucer in a warm room, and day by day the bulb sprouts and grows, and eventually flowers. I believe the colour of the flower is red or orange.—If. DE YARBURGH-BATESON.

In your "Short Replies" in your issue of March 22, page 54, you mention that "you cannot grow a plant without both soil and water." Permit me to say that Messrs. Carter, High Holborn, are sending out a tuber which they call "The Monarch of the East," and for which, so far, I have not learned the botanical name. I had two given me as a Christmas present, and at once placed them "in fancy saucers," as directed, one in a warm, sunny south window and the other in a kitchen north window, without an atom of soil, nor have they had a single drop of water. Both are growing well—the first now $\frac{3}{4}$ inch per day, and now 16 inches high. It is evidently of the *Arum* family, and I should be glad to know the botanical name.—SALF.

[It is only growing from stored up energy, as in the case of the *Hyacynth* or *Onion*, which will grow in the way you say, but will, as soon as this energy is exhausted, at once collapse.—Ed.]

Tropaeolum Jarrattii.—This pretty greenhouse climber is now making rapid growth, and the tender shoots must be trained to a wire trellis or a small Larch branch. It is a good plan to insert a few thin sticks in the pot, and to let the shoots run up them, nutwining them when they reach the top and tying them to the trellis. If this is not done they soon get entangled, and cannot then be separated. It succeeds best in a moist atmosphere, and must be shaded from bright sun. Weak liquid-manure may be given at each alternate watering, and the plants should be syringed on fine afternoons. The scarlet, yellow, and black flowers are extremely handsome and last a long time.—C.

TREES AND SHRUBS.

CYTISUS PRÆCOX.

CYTISUS PRÆCOX is generally in flower by the middle of April, and continues from that time well into May. In habit it is free and graceful, when in good health making annually shoots 1 foot or 1½ feet long, these being clothed from end to end with a wealth of soft sulphur-yellow blossoms. So abundant, indeed, are they that there is little else to be seen when the

Cytisus præcox. From a photograph by Miss Willmott, Warley, Essex.

this respect. *Lachenalias* are often neglected after flowering, being crowded together in a dark house or pit, and deprived entirely of water all at once. After flowering they should be placed in a light position in a cool house and be assisted with weak manure-water until the foliage turns yellow. Water should then be withheld. Treated thus the bulbs will swell to their normal size, without which flowers of the finest size and quality cannot be expected. At the end of May they should be placed at the foot of a south or west wall, where they will ripen thoroughly. In August, just as growth is commencing, they should be repotted. Turn the bulbs out of the pots, and separate the small from the large ones. The former, if placed in good soil in pans, will make good flowering bulbs for next season. The large bulbs should be potted in 6 inch or 8 inch pots, allowing them plenty of room, as if crowded the growth is sure to be weak and the flowers poor. Drain the pots well, as the *Lachenalias* are free rooters and require abundance of water. A compost of three parts turfy loam and one part well decomposed cow or horse-manure, leaf-mould, and coarse sand suits them best. I

fell away close to the crowns. I am trying to move them on, but they are very slow. They are in 7-inch pots. When they move I intend to put them into 10 inch pots.—A. C. T.

[*Hedychiums* do best when planted out, and to ensure flowering when grown in pots they must be divided from time to time before they get too much crowded, otherwise they do not make growth strong enough for flowering. They may be potted or planted out in good rich loam, with leaf-mould and manure added, and during the time they are making their growth they should be liberally supplied with water. They should be kept cool, and dry during the winter. When given a period of rest the plants flower better than when kept in heat throughout the year. The flowers, though very short-lived, are very beautiful.]

Plants to flower this year.—I should be much obliged if you will kindly let me know the names of about two dozen plants with handsome blooms which, when planted in the spring, will flower this year.—T. R. R.

[Your query is very vague, and we do not know what you require. This and may be best obtained perhaps by planting *Dahlias*; but whether you require permanent subjects as perennials or the like we have no guide. In the

plants are in flower. It produces a thick mass of shoots, which, although almost destitute of leaves even in summer, are of a lively green, and give the shrub quite the value and character of an evergreen. The odour of the flowers is rather too heavy to be pleasing, especially when the plants are grown in a large group. On this account it should not be planted close to dwelling-room windows and such places. As in the case of many of the Brooms, it is liable to become bare and leggy at the base. This is often due to neglecting the plants when young—st any rate, it may be prevented by careful attention to them at that time. The plants simply require to be topped occasionally from the time they are a few inches high till they have attained a height of about 18 inches. By doing this, a thick crop of branches near the ground is obtained, as seen in the illustration. The best way to increase it is by cuttings dibbled firmly into sandy soil in some sheltered, shady corner under a bell-glass or hand-light. Seed ripens freely, but only very few of the seedlings come true.

NOTES AND REPLIES.

An early-leaving Pear-tree (*Pyrus sinensis*).—This is known as the Sandy Pear or the Snow Pear, and does not appear to be very common in collections of ornamental trees. It is now in full leafage (March 20th), and the glossy bronzy red hue is very fresh and effective as seen amongst other Apples and Pears, which are so far only in the bud stage. Our tree is about 30 feet in height, and is very effective in the March sunshine, and a nice companion to the pink-blossomed, but so far leafless, Almonds. Now and then its flowers are produced, and a sparse crop of small sandy or gritty Pears follows, but the chief interest and beauty of the plant consist in its early-leaving habit. Speaking of Pear-trees, I may say that the noble old specimen of the Jargonelle on the front of No. 11, Merrion-square, Dublin, is now very densely set with blossom-buds, and promises to be very beautiful in a fortnight's time. It was planted in 1814 by the late Sir Philip Crampton, and is one of the finest of town-grown Pear-trees I have ever seen.—DUBLINERIAN.

Treatment of Myrtle.—My Myrtle, about which you gave me advice, is doing beautifully now, and budding after having lost all its leaves. Is that natural to it every spring, and how long ought it to remain untouched in its big tub, as it has no drainage?

[The Myrtle is naturally of an evergreen character, and, though some of the oldest leaves drop just as the young ones push forth in spring, it should certainly not lose all its leaves as yours has done. Two reasons for the leaves dropping may be suggested—firstly, exposure to frosts sufficiently severe to injure the foliage but not enough to kill the shoots; and, secondly, extreme drought at the roots during the winter months. When once established in a large pot or tub the Myrtle will keep in health for years without being disturbed at the roots. You mention that the tub in which your plant is growing has no drainage, hence we should advise you to bore three or four holes in the bottom, so stagnant moisture is very injurious to all classes of plants. If at any time you decide to repot or retub it, place some broken crocks in the bottom, and these in conjunction with the holes will ensure drainage. In the case of Myrtles that have been standing in the same pot or tub for years, and which it is undesirable to disturb at the roots, a little weak manure-water in which some soot has been dissolved will, if given about once a fortnight during the summer months, be of great service.]

Rivina humilis.—Few berried plants are so useful in winter as this, especially for dinner-table decoration and mixing with fine-foliaged plants and Ferns in a warm conservatory. Its culture is comparatively easy, and by sowing seed at various times it may be had all the year round. To ensure well-berried plants in autumn and winter the seed should be sown in March or early in April. Sow it in a pan of finely-sifted loamy and leafy soil, and place it in a temperature of 60 degs. to 65 degs. Cover the seed pan with a piece of glass to help in keeping the soil moist and also to ward off mice, as these pests are very fond of the seed. As soon as the seedlings can be handled put them into small pots in a mixture of loam, peat, and

leaf-mould, in equal portions, with sufficient silver-sand to keep it open. Give them a position near the glass and shade from the sun for a short time; syringe them daily and keep the atmosphere moist, as in an arid atmosphere the foliage soon turns yellow. Give them a shift into 4½ inch pots before they become root-bound, and assist them with weak liquid-manure at each alternate watering. Standard plants, from a foot to 15 inches high, are the most useful, especially for table-decoration, and the best way to procure them is to remove all lateral growths until the plants are of the desired height. The point of the leading shoot should then be pinched out, a sufficient number of buds to form a bushy head being retained. For the production of later plants seed may be sown in a sunny greenhouse or pit in April, and the plants grown there during summer, but they must be removed to rather warmer quarters in October, or the foliage will turn yellow and the appearance of the plants be spoiled.—SCOFFER.

CHRYSANTHEMUMS.

CHRYSANTHEMUMS—STOPPING AND TIMING.

(REPLY TO J. FULLER.)

THE chief reason for stopping or pinching Chrysanthemum plants is that they may develop buds at the time best suited to their peculiarities, and that they may be had in flower during the period covered by the November shows. Yours is a comprehensive list, and embraces many fairly new and choice varieties. Treat your plants as follows:—

Name.	When to pinch the plants.	Which buds to retain.
Van den Heide	At once	Second crown
Chas. Davis	Natural break	Any buds and August
William Seward	Natural break	Second crown
Golden Gate	First week May	First crown
Mrs. Carnot	About April 15th	Second crown
Mrs. W. Mease	About April 15th	Second crown
G. J. Warren	About April 15th	Second crown
Lady Hingham	Natural break	Any buds and August
Viviant Morel	Natural break	August
Phloxia	Natural break	Second crown
Lady Lawrence	End April	First crown
Mrs. M. Reaid	Now	Second crown
Good Gracious	Now	Second crown
Joseph Chamberlain	Now	Second crown
Moderate	Now	Second crown
Rose Wynne	Natural break	Second crown
Waban	At once	Second crown
Le Grand Dragon	Now	Second crown
Eva Knowles	About May 15th	First crown
Eta Press	Now	Second crown
The Queen	First week May	First crown
Delightful	Try May 20th	First crown
Matthew Hodgson	Now	Second crown
Niveum	First week May	First crown
Australian Gold	Natural break	Second crown
Golden Wedding	About May 10th	First crown
Hairy Wonder	Second week April	Second crown
R. Hooper Pearson	May 21st	First crown
W. Adams	Early May	Second crown
Mrs. Berkeley	Now	Second crown
Queen of the Field	At once	Second crown
Victor of Bay	Now	Second crown
Chas. Bick	May 15th	First crown
Oriana	Natural break	First crown
H. Weeks	Now	Second crown
Mrs. White Popham	Natural break	First crown
Mrs. G. W. Palmer	Natural break	Second crown
J. R. Epton	Now	Second crown
John Hirdman	Natural break	Second crown
Graphic	Now	Second crown
Simply	Now	Second crown
Mrs. Chas. Bick	Now	Second crown
Chas. H. Curtis (Jr.)	Now	Second crown
Mrs. P. R. Hinton (Anem.)	Now	Second crown
Black Hawk (dec.)	Pinch plants two or three times, last time end June, securing first buds subsequently.	
Mrs. H. Weeks	Secure first buds developing in the point of the shoots.	

CHRYSANTHEMUMS TO FLOWER IN NOVEMBER AND DECEMBER.

WHAT you kindly give me the names of about a dozen Chrysanthemums for flowering during the latter half of November and early December? Those only which want slightly disbudding I prefer.—R. O.

[To secure free-flowering plants they must be grown on to the terminal buds, and to be seen at their best it would be wise to slightly thin out the more crowded and unshapely buds from the cluster which develops at the apex of each shoot. Some of the sorts flower freely without being unduly crowded, this fact being accounted for by reason of the splendid length of footstalk on which the individual blooms of the cluster are developed. This is the best type of plant

to cultivate, as there is no waste, and the culture is very simple. Procure rooted cuttings or established plants of the following:—

Mrs. JAMES CARTER.—This is one of the more robust of the spidery sorts, and although its habit leaves much to be desired, nice, bushy specimens may be obtained by pinching out the point of the growth two or three times during the growing season. Let the last pinching be done during the second week in July. The flowers are made up of numerous thread-like petals, and the colour is pale yellow. Height about 4 feet.

L. CANNING is a well-known pure white Japanese variety, which may be had in flower at any time between the end of November and January. The flowers do not possess as much substance as most growers would like, yet the blossoms are dainty and pleasing. Height about 3 feet.

Mrs. ALICE BYRON.—This is a lovely bloom of the purest white, and when obtained from terminal buds makes a handsome display. Height about 3½ feet.

Mrs. FELIX PERRIN.—This is the best of its colour in the Japanese section for late work, and may be had in good condition at any time between the early days of December and some weeks later. The colour is a pleasing shade of soft rose-pink, and it is now largely grown for market. Height about 4 feet.

CHILINGFORD.—This is one of the brightest flowers available for late November displays. The colour may be described as bright crimson with a golden reverse, and the plant is exceptionally free-flowering. The habit of the plant is erect and bushy, and it attains a height of about 3½ feet. The flowers belong to the reflexed type of the Chrysanthemum, and a decade since it was a very popular exhibition sort.

Mrs. GABRIELLE DEBBIE.—On account of its charming flesh-pink colour this Japanese variety should be grown. It is not generally regarded as useful for the purpose under notice, but by carefully disbudding the overcrowded terminal buds good results may be secured. The plant attains a height of about 5 feet, or rather more.

Mrs. PHILIPPE RIVIERE.—A very well-known late-flowering white Japanese, which may be had in blossom during November and December. Creamy-white well describes its colour, and it is a plant of fairly easy culture. Height about 5½ feet.

G. W. CHILDS.—This is another beautiful, velvety crimson flower of Japanese form, at its best during the period described by you. As the rich and brightly-coloured varieties are a limited quantity, full advantage should be taken of those included in this selection. In this instance the plant attains to a height of about 5 feet.

NIVEUM.—This is a well-known snow white Japanese sort of the highest value. To be seen at its best, however, the terminal buds should be liberally thinned out. The flowers are large, and the plant fairly free-flowering. Habit vigorous; height rather more than 4 feet.

PHILIPPE RIVIERE.—In this refined flower we have a charming primrose-yellow sport from Niveum. The plant possesses all the excellent characteristics of the parent, and should on this account receive similar treatment. Disbud rather freely.

Mrs. EDMOND PAYNE.—The only representative of the incurved section in this selection, and included in the list because of its pleasing colour, which may be described as white, with green centre. The plant should be grown freely, otherwise the blossoms are less attractive. Late November should see the plant at its best. Dwarf.

Mrs. COOMES.—For late November use this easily-grown kind should be flowered from terminal buds, taking care, however, to pinch the plants for the last time during the second week in July. Its lovely bright rosy-mauve colour has made this kind a great favourite. Splendid habit.

Mrs. CHARLES MOLIN.—This is another instance in which a mid-July pinching of the plants will give excellent results from terminal buds in late November. The colour on late buds is orange-red and very effective. The flowers are rather large, and, in consequence, the buds should be slightly thinned. Height 4 feet; vigorous habit.

MRS GREENFIELD.—This is rather new, but its beautiful rich glewing yellow colour places it in the front rank. The plants should be pinched two or three times during the season—the last time in mid-July—and the terminal buds slightly reduced in November. Good habit, and reliable.—E. G.]

NOTES AND REPLIES.

Chrysanthemums—stopping and timing (*Chrysanthemum*).—Assuming your plants were propagated during D. amber, or even rather later, they should be treated as described below:

Name	When to pinch or stop	Which bud to retain.
Calvat's 1899	April 2nd week	Second crown
Lady Hamham	Natural break	Second crown
Lord Hamphrey	April 1st week	Second crown
Lord Ludlow	April 1st week	Second crown
Mons. Chamon de Leche	Natural break	Any buds late August
M. Louis Remy	Natural break	Second crown
M. T. Carrington	Mar. last week	Second crown
Mrs. Coombes	Natural break	Second crown

The treatment suited to Le Grand Dragon, Mme. Caront, Mrs. Barkley, and Vivand Morel is given in reply to another correspondent in this issue.

Early-flowering Chrysanthemums—spring propagation.—At the present time old stools which were lifted from the open some time ago are bristling with shoots of a healthy character. There is no better material with which to increase these hardy outdoor sorts. The more genial weather of late has caused the growths to develop, and these may now be detached and made into cuttings about 3 inches in length, and inserted at once. These cuttings may be inserted in shallow boxes filled with equal parts of loam and leaf-mould, with a liberal addition of silver-sand, at a distance of about 2 inches between each cutting and rather more between the rows. From a healthy stock obtained at this season, far better results are generally obtained than by a mid-winter propagation. Those who have to procure cuttings from the trade specialists should now be able to purchase them very cheaply indeed, as a little later they will be thinking very likely of throwing the old stools away.—A. R.

VEGETABLES.

SOWING PEAS.

PEAS enjoy deeply-worked soil, well enriched with animal-manure. It is not necessary, as some advise, to trench 3 feet deep, putting a layer of manure in the bottom of the trenches at that depth, and two other layers between the succeeding spits. It is, however, well to remember that in preparing the ground for Peas, another succeeding crop, or, it may be, two, will derive benefit as well.

For small gardens I have come to the conclusion that dwarf Peas are more remunerative than tall ones. The Marrowfat section is that which affords the greater satisfaction, and now that there is such a wide range in this section, there is no necessity to cultivate the smaller round-seeded Peas. Fewer seeds of the Marrowfat section are necessary for sowing, on account of their freely branching habit, so that the cost, which is proportionately more in wrinkled Peas, is partly met in the less quantity needed. They are much more remunerative when their height is made by good culture to exceed that given in seed catalogues by, say, 9 inches to a foot. This I have proved can be done easily by deeper tillage, a little extra manure, and thiner sowing than is commonly practised. An ordinary selection of American Wonder I do not consider worth growing, compared to some of the later introductions. Yet this is often chosen, more perhaps because it is cheap, and better known by name. Little Marvel, Excelsior, Chelsea Gem, and Daisy grow with me to a height of 2 feet, and were freely podded from the ground. Earliest Dwarf Hardy and Dwarf Defiance are others that may be named. While deep digging or trenching is necessary for the early summer sorts, it is still more so for those that come in from July to September or October. When sowing, it is desirable to open the drills to a good width and depth, and when the seeds are disposed thinly along the drill I like to tread them in. In sowing early Peas it

is not usually necessary to provide for watering them, but later sowings should be attended to in this respect. If, in sowing, the drills are drawn out more deeply with the hoe, and the seeds trodden in, it is easily possible in covering to provide a depression efficiently deep to hold water when poured in later on. Even these dwarf Peas should have light stakes put to them to keep them upright, as they do much better kept off the ground. W. S.

MANURE FOR PEAS.

Of late much has been written as to which manure was the better—fermyard manure or artificial manure—for Peas, and up to the present the latter appears to be in favour with the majority of writers, though I doubt whether in the long run it will ever entirely oust stable or fermyard manure from being used for this crop. In the principal gardens of the United Kingdom this kind of manure has to be utilised for the production of vegetables, and often without one peck of artificial manure ever coming into the garden, and yet we find year after year good crops of Peas forthcoming, and should they fail it is usually the midseason crops right in the height of summer, when the ground is so parched that scarcely any vegetation is moving. If those cultivators who favour these made-up manures can assure us (who stick to the old utrogannous manure) that they are able to gather good dishes of Peas when, comparatively speaking, we have few, if any, to pluck, then I for one shall feel convinced that the sooner the old fallacy is exploded the better. In the meantime, having followed this practice during the past seventeen years, and with good results, I shall still continue to follow it up while good stable or cowyard manure can be had. A fair dressing of this, dug down a foot or 14 inches deep in December or early in January, and the ground ridged and allowed to remain uncropped until early in February and onwards, when petiole sowing have to be made, will stand all leguminous plants in good stead during long spells of drought. Where mistakes are often made with this crop is not watering freely enough, it causing far more harm than good to put on just a few pottles once a week or ten days and think the crop should be good. What is required during spells of drought is to pull up the soil on either side of the row and deluge the roots twice, if not thrice, each week, and a good doeing overhead with the garden engine or syringe of an evening will tend to ward off thrip—so destructive to the Pea family—and should mildew appear dust with flowers of sulphur after the syringing has been done.

Some prefer trenches for late Peas, prepared as for Coleby, but I prefer sowing on ground that has been deeply dug, as previously advised, considering that the roots are curtailed far too much when enclosed, as it were, between two walls, and should the supply of water fall short the plants soon succumb. If trenches are employed, let the surrounding ground be well worked so that the roots can extend right and left in search of food if necessary. In every well-ordered garden Peas do not entirely depend upon the manure placed underneath their roots, for what gardener does not at some period or other of their growth dust the plants with slaked lime, soot, or wood-ashes to ward off slugs, birds, etc., either one of which is of much value as a top-dressing, but not absolutely necessary for the welfare of the crop when nitrogenous manures are placed within the reach of the roots. J. M. B.

NOTES AND REPLIES.

Broccoli Spring White.—At the present time I am cutting nice white compact heads of this Broccoli, which are all that can be wished for when cooked. It is a useful sort for giving an early supply, and the stems being of medium height, and the curd well protected by an abundance of leaves, it is less susceptible to severe frost than some other early sorts. The present is the proper time to sow seed to obtain plants for yielding a supply in the corresponding period next year.—A. W.

Sowing Lettuces early under glass.—In some places it is difficult to keep young Lettuces through the winter in the open. Again, the crop often suffers from frost should the plants be too large. I sow three times in the autumn, and out of these, one sowing generally

pulls through. My first and second sowings this year have suffered, the major part having gone off by Christmas. Even with this provision I always sow a box of two sorts at the end of November, keeping those on a shelf in a cold Peach-house. I sow again early in the year, placing the seed in a close house till it begins to germinate, when it is put on the same shelf. I prefer sowing Lettuces and many other things in boxes to frames, as in boxes they can be moved and kept berdy, which is of much importance when required for planting in the open ground. Any quick-growing kind may be sown from now onward.—J. Crook.

Lettuces.—To maintain a constant supply of good Lettuces during the summer months often taxes the best capacities of the grower. To overcome this difficulty it is a good plan to make small sowings in a pen or pans, in shallow boxes, or under handlights, every fortnight, as then there is no lack of plants, and if sown thinly these will be sturdy and strong to transplant. The common defect in Lettuces growing is sowing the seeds so thickly that the little plants are crowded, weak, and poorly rooted when they are large enough to transplant. It is little wonder if then, under hot sunshin, they lieger on, presently make growth, then bolt off to flower because incapable of producing hearts. When Lettuces plants are sturdy and well rooted, then planted out into good soil, well watered, and for a few days shaded, they soon get hold of the ground, grow rapidly, and finally heart in well. To have them good the soil can hardly be too rich, as the more rapid the growth the crisper is the leafage.—A. D.

Shallots.—Where it has been needful to press the bulbs of Shallots somewhat firmly into the ground, they having been lifted by frosts if early planted, it is well, so soon as it is seen that roots have formed and growth has commenced, to draw away some of the soil from them, as there can be no doubt but that the best and cleanest clusters are found on the surface. It would be an excellent thing were classes at shows, and especially at cottage garden shows, to be for the best six or nine clusters of bulbs rather than for the best twenty five or so of picked bulbs. The average character of the cluster tells more as to the general excellence or otherwise of the crop than do selected bulbs. Shallots like well-manured soil, and where it is stiff some sharp sand should be added where the bulbs are planted. Large bulbs are less desired than are handsome, clean, glossy ones, even in size, and well matured. Shallots are grown apparently in all cottage gardens and on allotments.—A. D.

Vegetable Marrow.—Generally growers of this now almost universally grown vegetable like to have rather large fruits. The impression seems to be that so long as the rind is soft the larger the fruits, the better. It is just possible that as the fruits become large they comprise rather more of flesh and rather less of water, but in no case have even the very best of Merrows much of solidity in them. But whilst plants may be labouring to produce two or three large fruits, they are capable of producing others, hence there is little or no gain found in having big fruits. At exhibitions handsome smooth, white, long froite are most appreciated, if the pair be equal in size, fresh, tender, and free from abrasion. But all the same, they must not be too large or the skins will have hardened. To have Merrows presented at table in the most perfect condition, they should be cut young, be cooked whole, and unpeeled, and so served to table. At that time seeds will not have developed. It is time seeds of any varieties were sown under glass, so as to have strong plants to put out in May. A. D.

Carrot pests.—Carrots are often attacked by insects, the two worst being the Carrot-grub and Carrot-fly. Where the grub is troublesome the ground intended for Carrots should be ridged up to expose it to the frost. A liberal quantity of soot and gas-lime, also some burnt garden refuse, should be incorporated, these ingredients being obnoxious to the grub. After sowing the seed strow some wood ashes or burnt refuse over it before filling in the drills. As soon as the plants are up dust them over with soot and wood ashes in equal quantities, as it is then that the fly usually attacks them. The operation should be repeated every ten days till the plants are about 4 inches high. The grub

often attacks the plants after they have grown to a considerable size, and if not destroyed soon riddles the roots. To destroy it put a bushel of scot and one of fresh lime into bags and soak them for 24 hours in 100 gallons of water, then well water the Carrots overhead with the liquid.—J.

Transplanting Onions.—Many now raise their Onions under glass, harden off in frames, and transplant them early in spring. The plan is an excellent one, and should always be adopted where the soil is light or the Onion-maggot troublesome. April is the best time for transplanting, and great care is necessary, as the roots are easily damaged. The practice of planting with a dibber and thrusting the roots into a small hole cannot be too strongly condemned. A trowel should be used, and holes made sufficiently large to hold all the roots without crowding. They should be spread out evenly, and some fine soil placed on them and made very firm. If extra large bulbs are wanted, allow a space of 6 inches between the plants and 12 inches between the rows, and mulch with old Mushroom-mansure. If the growth is at all dry, give the plants a good watering immediately after planting.—SUFFOLK.

GARDEN WORK.

Conservatory.—Give Arum Lilies and Pelargoniums coming into flower liquid-mansure twice a week for a short time. The house will be gay with Azaleas, Spiraeas, and forced shrubs now. One gets tired of bulbs under glass after they come into blossom outside. Tea and other Roses will be in good condition now, as they will be coming on quietly without much forcing; these, also, should have liquid-mansure. Good-sized bushes of white and yellow Marguerites are useful, and are easily grown. The best plants for flowering now are cuttings struck rather late last spring, cut back rather late in summer, started a little till the new growth comes away, and shilled into 5-inch and 6-inch pots. These may be divided into two batches, the largest plants to flower in a light house in winter, and the others kept cool to come on early in spring. Canterbury Bells are bright and showy plants in a cool-house in April and May, and I am specially partial to Forget-me-nots and white Pinks. Of course, these, to flower early, must have special preparation. The Forget-me-nots must be potted up in autumn, kept in a cold-frame, freely ventilated in winter, and moved to the greenhouse as soon as the days begin to lengthen. To flower early cuttings of Pinks should be taken from forced plants in February or not later than March. When rooted and hardened off they should be planted in a well-prepared bed outside and potted up in September, the largest plants in 6 inch pots and smaller ones in pots 5 inches in diameter. Winter in cold-frame and move to greenhouse in January or February; they flower best when brought on quietly. The Bleeding Heart or Lyre-flower (*Dielytra*) gently forced, is charming just now in good-sized pots. The imported roots are cheap, but they flower best when established in pots. They are easily grown, and after flowering should be cooled down and then plunged outside, but not altogether neglected and forgotten. Plants in pots will require more water now; some plants, such as Hydrangeas and other strong-rooting plants, will require water twice a day. Spiraeas, to keep them in condition, should stand in pans containing water.

Stove.—Among the smaller kinds of plants which may be successfully grown in the amateur's small stove or forcing-house are Gloxinias, Streptocarpus, Gesneras, and Achimenes. All the above, except the Gesneras, may be grown in the greenhouse in summer. All they want is a moist, warm house to start them into growth and enable them to make healthy progress till the flowering period arrives, and then be moved to a cooler, freely-ventilated house. All may be easily raised from seeds or cuttings, and, of course, the bulbs have a permanent character, and, after flowering and a period of rest in a dry state, except the Streptocarpus, which are virtually evergreen, they start into growth at this season or earlier with renewed vigour. Gloxinias and Streptocarpus have been much improved lately, and come very good from seed. Achimenes and Ges-

neras have not been so much in demand of late years. If shifted on into large pots, Gloxinias and Streptocarpus will make very large, handsome plants. Place a strog bulb in a large pot, and deal liberally with it in the matter of compost and liquid-mansure, and the reward will come in the shape of grand plants a yard in diameter in 10-inch or 12-inch pots. At the last shift the drainage should be very free, and the compost richer and more turfy or fibrous in character, freely intermixed with crushed charcoal and coarse sand. The compost for all stove plants potted now should be in this condition.

Ventilation of fruit forcing-houses.

—This is very important work now. When the growth is young and tender air should be given in small quantities at a time. The character of the house has to be considered. Some glass-houses get hot much sooner than others, influenced by the aspect and the pitch or slope of the roof. In exposed or windy places I have found it necessary at this season to tack hexagon netting over the ventilators to filter the cold air through in March and April. Fresh air is not required on cold days, even when the sun is bright. Better use more moisture and avoid cold currents. See that there is no leakage from the gutters in front of the house, as many a crop of early Grapes has been seriously injured by a temporary overflow of a gutter or some such simple matter. When Grapes are in bloom the night temperature may be started at 65 degs.; a degree or two more or less will not make much difference. At 75 degs. the ridge ventilators should be opened an inch or so, not for the purpose of lowering the temperature, but to prevent a too rapid rise. More air will be required as the temperature increases. A man who watches the weather can tell when more air is required without continually running to look at the thermometer. Peaches all round will do with a lower temperature than Grapes during the time the trees are in blossom, 50 degs. at night will be high enough; air to be given at 60 degs. The art of forcing is to a considerable extent to imitate Nature—to commence at a rather low figure, and gradually work upwards as the season and the growth of the forced subject advances.

Thinning Grapes.—It is best not to handle the berries when thinning. Those who cannot do without handling the bunches should wear a soft, clean glove. Most men use a smooth bit of bone or wood to move the berries into position where the bunches are large. Personally, I do not care for large-shouldered bunches, and in thinning reduce them and trim them into shape generally to make the bunches compact and of a reasonable size. A crop of Hamburgs that will average 1 lb. or 1½ lb. per bunch is more useful than a few loose bunches of large size. Of course, the tyre in Grape-growing knows that the small berries should be cut out and the large ones which have taken the lead left, as nearly every kind of fruit, whether it be a Grape, a Peach, a Melon, or a Strawberry, which has got a slight lead will retain it.

Window gardening.—There is likely to be a larger demand this season than usual for plants for window-boxes, and the three colours—red, white, and blue—are likely to predominate. In towns the Carnation week will be the gay time, and the flowers then must be at their best. There is a wonderful easiness generally about window-boxes. I would suggest that the Tulle Pansies or Violas should have a turn. They will be well in bloom in June if planted now. Do not paint the boxes so glaringly green; choose a softer tint, and plant some kind of greenery to hang over to tone it down still further.

Outdoor garden.—Roses which have not been moved are breaking into growth, and, if not already pruned, attention should be given to them at once; but there is time enough for Teas and the late-planted Roses of all kinds. Roses which were planted in November are making roots freely. I have moved Tea Roses in April without loss. All recently-planted Roses should be cut rather hard back; the growth comes away stronger and the flowers are much finer. If the Roses budded last season have not been headed back, see to it at once, and the buds will start strongly, benefited by the long rest. Dormant buds make the best buds and produce the finest blooms. As soon as the

growth gets fairly started support should be given to prevent the wind blowing the shoots out. Rose pruning has been often discussed and is pretty well understood now. Weakly growers should be cut back to three buds; strong growers to 6 inches or 8 inches, in proportion to strength. The heads of standard should be thinned by the removal of weak shoots. Hollies and other evergreens will move well now. Water them well in and damp the foliage daily in dry weather. Mulch as soon as planting is finished, and stake or otherwise secure from wind all tall plants. Sow all kinds of hardy flower seeds. This is a good season to buy new hardy plants; plant these things in a reserve bed first season.

Fruit garden.—We have not had our average rainfall yet, and all newly-planted trees will probably require water. New beds of alpine Strawberries may be made now to bear in autumn. Other kinds of Strawberries may also be planted now, but, of course, no fruit should be expected this season; but we have had our best and healthiest runners from plants set out in March. The plants were strong and moved with good roots from the nursery bed, where they had been quietly preparing for the move during the winter. The grafts are going in well now, and all inferior kinds of Apples and Pears should be headed back and regrafted with better kinds. Those who wish for profitable market Apples should grow Cox's Orange Pippin and Bismarck in quantity. Lane's Prince Albert will also pay its way. One of the best dessert Apples now is Lord Burghley, and it bears better on the Paradise than the Creh. If the mite is among the Black Currants, cut hard back and burn all prunings, and mulch with manure rather heavily. Black Currants do best in a damp, rather rich soil. Newly-planted Raspberries should be cut down to within 6 inches of the ground the first season to secure good canes for next year's bearing. Never take your canes for planting from exhausted plantations.

Vegetable garden.—Among Spinach substitutes the best are Spinach Beet and New Zealand Spinach. The Beet may be sown now in drills 18 inches apart, and the New Zealand Spinach (which, of course, everyone knows is not a Spinach at all) is usually sown in heat, hardened off, and planted out in May or early in June. Sow the seeds in small pots, three seeds in each pot, and place them in the hotbed, moving to a cooler place when some progress has been made. A first sowing of Broccoli and Winter Greens should be made now. Brussels Sprouts for the first crop are either sown in autumn or in heat in spring, pricked off and encouraged to grow, ready for going out by the end of May or very early in June. Sow Lettices, Radishes, and Turnips often and in small quantities. What is termed Summee Spinach may be sown as a catch crop between early Peas or elsewhere. If plenty of Winter Spinach was sown in autumn, there will be a supply from then till June. I have prolonged the supply by cutting every alternate row down early in April. This prevents the plants running to flower and seed, as fresh young growth starts away from the bottom and gives very tender leaves. New plantations may be made of Horseradish. Plant the Chinese Artichoke. E. HODDAY.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

April 7th.—Sowed main crop of Carrots and Long-rooted Beet. Sowed more Melon and Cucumber seeds; also New Zealand Spinach and Sweet Basil for planting out later. Put in cuttings of young shoots of Tarragon to raise young plants for planting out. Sowed Chervil. Placed a little warm earth round last lot of early Potatoes in frames after soaking with liquid-mansure. We are still putting in cuttings of various things.

April 8th.—Shilled 2nd lot Ceraniums into blooming pots. Some of these will be used to fill vases and tube about the terraces. Put in cuttings of Hydrangeas. We grow a lot of cut-back plants in 8-inch pots, which usually carry from six to nine large trusses of blooms each. Round the base of these plants are numerous young shoots, which make excellent cuttings, which strike immediately in a warm, shady

place. Pricked off seedlings of various kinds into boxes. Planted Potatoes.

April 2th.—Planted more Gladioli, Hollyhocks, and a few new Phloxes, which have just come to hand. We group our Phloxes in separate colours, such as a group of crimson, and next a group of white, a dozen plants or so in a group. Hollyhocks are treated in the same way. Moved several large green Hollies. Pruned and tied in several Irish Yews that were getting a bit loose from wind pressure.

April 10th.—All Peas are sown in good time so that the tendrils may have something near to cling to. Marrow Peas are sown very freely now. Antocrat was regard as one of the best kinds. Ne Plus Ultra has been a favourite as long as we can remember. It is rather too tall for a small garden. Dusted a little more Tobacco-powder among the young shoots of Peaches on walls. Pricked the longest shoots of Fuchsias to make them compact.

April 11th.—Pricked off early Celery into frames. A layer of manure is placed in the bottom and then 3 inches of good soil on top, into which the young plants are planted 4 inches apart. When more room is wanted they will be moved to trenches. The Leamington Broccoli when true is very distinct and hardy, and throws a close, white heart. Sowed Winter Greens of various kinds. Sowed Troieps in succession quantities.

April 12th.—Planted green Windsor Beans. Scattered a little soot on Onion beds. Made a successional sowing of Sweet Peas. The plants of Sweet Peas raised in pots have been planted, earthed up, and staked. A few are growing in baskets in the conservatory. In this position they flower freely. Transplanted Asparagus to make new plantation. The plants were 2 years old. Planted young Pentstemons from cold-frames. Sowed various hardy annuals.

POULTRY.

COMMENCING POULTRY KEEPING.

(REPLY TO "EAST SUSSEX.")

This is a good time to begin poultry keeping by purchasing pullets hatched early last season. They will now be laying, and so will cost a little more than if obtained in the winter. It would be advisable to start with a small number, and if only a small run can be given, the object should be to supply new-laid eggs, as rearing table poultry without a good range would be almost certain to end in failure. Andalusians would prove suitable, being hardy, and laying freely in confinement. Another breed that does well in a limited run is the Black Minorca, which is a non-sitter, and lays a quantity of good-sized eggs, besides being a handsome fowl. Where the soil is damp and cold, the poultry-run should be raised a foot or so by adding chalk, old mortar, or bricklayers' rubbish, while it is well to shelter the run from the north and east. About 5 square feet should be allowed per head. Galvanised wire-netting is the best material with which to enclose poultry-runs. The netting can be attached to iron standards or stout posts well fixed in the ground. The height of the netting must depend upon the kind of fowl kept. If, however, the top be wired in, 3 feet or 4 feet for the sides is sufficient. A shed for the hens to take shelter under in wet weather in addition to the roosting place always proves valuable, and if the ground be dry and well drained it may be left in its natural state for the fowls to scratch in, and be dug over from time to time to loosen it up. A heap of sifted coal-ashes should be provided in a sunny corner of the shed for the fowls to dust themselves in. This dusting is materially instrumental in preserving their health, and, to provide material for the egg-shells, a good supply of chalk, mortar-rubbish, or broken oyster-shells should be kept in a dry corner; otherwise, the hens will be liable to lay shell-less eggs. Fowls kept in a small run must be liberally provided with green food, besides being allowed a small quantity of animal food to take the place of insects and Grass they would obtain if at liberty. S. S. G.

Fowls for enclosed run (Wykenham).
—Your Buff Orpingtons ought to be laying by this time, although highly-bred fowls seldom lay so well as those that do not come from exhibition parents. The Black Minorca stands in confinement well, is a non-sitter, and lays a

quantity of good-sized eggs, although rather sensitive to cold winds. Another very good breed for a limited space is the Andalusian. It is very hardy and a free layer of large eggs. Leghorns, of which there are several varieties, are splendid layers, especially the white kind. If brown eggs are preferred, Langshans will be found satisfactory, being good winter layers, standing confinement well, and very hardy. Wyandottes are also excellent layers, and do well in a small space. These also lay a brown egg, and either the silver or golden variety would be found suitable, although the silver is generally considered the better layer. Buff Cochins are very suitable for a limited space, as they are naturally disinclined to roam, and although not such free layers as some of the above, still they give eggs at a time when they are very scarce.—S. S. G.

BIRDS.

Death of Canary (A. Burney).—You appear to have given your bird every care and attention, but, unfortunately, the mixed seed you have been feeding it on contains a quantity of Inga, which is most injurious and sure to bring on, sooner or later, liver disease and other internal complaints. In this case there was inflammation of the bowels. The plumage had not become thoroughly dried after the bird had taken its last bath, and this, no doubt, caused a chill which proved fatal, it being already in a low state. It was exceedingly thin, and had, doubtless, been ailing for some time. The "Hartz Mountain bread" is very good for helping Canaries over their molting and at breeding time. Unless you can obtain packets of mixed seeds that are free from Inga, it would be advisable to buy Canary seed and Rape and mix them yourself, adding a very small quantity of Hemp. Nothing could have saved your bird, for, unless the complaint it was suffering from is taken in hand at the very commencement, there is no cure.—S. S. G.

—(C. H. Angel).—Inflammation of the bowels caused the death of your bird. This is, unfortunately, a very common complaint of our feathered pets, and is brought about in many instances through a chill after bathing, and also through a sudden lowering of the temperature. Partaking of unsuitable food will also cause this disease. You do not say what this bird was fed upon, and so many complaints of cage-birds arise from errors in diet that it is important to furnish full particulars in this respect when sending a bird for examination. Many seeds, such as Hemp, Maw, and Flax, if partaken of freely, soon cause disease of the internal organs, while Inga seed proves fatal through bringing about liver disease. Egg food also proves injurious in many instances, although commonly supplied to birds put up for breeding. It was rather too early in the season to pair your Canaries. The earliest time to make a beginning should be at the end of March, and better still if April be first reached. Green food is an important item in the management of breeding birds, and may consist of young Dandelion, Watercress, or Lettuce.—S. S. G.

LAW AND CUSTOM.

Private tenant may not remove fruit-trees, etc.—The house in which I reside has been in my lease for nearly fifty years. There is a large garden attached, which was peacefully enjoyed when I first took it. I have gradually formed a valuable collection of halle, Roses, and herbaceous plants, and have now received notice to leave. Can I remove any of them to a new garden?—M. M.
[You cannot remove any of the plants that remain permanently in the ground. Anything taken up for the winter and not yet replanted may be removed.—K. C. T.]
A gardener's notice.—Is a head gardener, living off the premises and paid weekly, subject to one week's notice?—G. I. R.
[This is a doubtful question. Something depends upon the number of men he has under him. If the payment of a weekly wage is the only circumstance from which any indication of the duration can be drawn, a week's notice would probably be held sufficient, but the point is not free from doubt.—K. C. T.]
Mortgage and Income tax.—I have a small piece of land which is mortgaged. When paying the mortgagee's interest am I entitled to deduct income tax in respect of same?—ORCHARD.
[If you have paid Income tax to the amount of the tax on the mortgage interest, you may deduct it at the current rate when you pay the interest. It does not matter in respect of

what property Income tax was charged on you—so long as you paid Income tax in respect of anything you may make the deduction.—K. C. T.]

A question of contract.—I undertook to reseed some turf at the price of 2s. per grave, my employer offering to pay for the turf. When I went for the turf I had to cart and cart half a mile, and was charged for it at trade price. My employer now declines to pay for the carting and the cartage. Can I recover my charges?—S. J.
[If your charge for cutting and cartage is of reasonable amount you may recover it in the county court. In the absence of any express contract to the contrary, the undertaking of your employer to pay for the turf means the paying for it delivered at the graveyard.—K. C. T.]

Claim for Strawberry beds.—I occupy a house and garden at the annual rental of £10, and I am a Strawberry grower for market. The place has been sold, and I am under notice to quit on April 15th this year. My Strawberry beds have been down two years. Can I remove the plants, or claim compensation for them? If not, can I lawfully destroy the plants?—CARTON.
[You cannot lawfully destroy the plants, neither can you remove them; but as a market gardener you may claim compensation for them under the Market Gardeners' Compensation Act. You must make your claim upon your landlord before midnight on April 6, but you may make it as much earlier as you like—the day you read this, if you choose. No particular form of claim is necessary.—K. C. T.]

Wanted, a shelter.—I am not a tramp, but an enthusiastic outdoor gardener, and greatly object to being knocked about by rain or driven from my beloved plants by most inconsiderate hailstones. Can any of your clover northern readers (said to have the sharpest wits) tell me if it would be practicable to make a light shelter or tent that could be moved easily among flower-beds?—V. E. R.

CORRESPONDENCE.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow these rules: All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF GARDENING, 17, PATERNOSTER-STREET, HOLBORN, LONDON, E.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation, as they desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper, and not more than three queries should be sent at a time. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, queries cannot always be replied to in the issue immediately following the receipt of their communication. We do not reply to queries by post.

Naming fruit.—Readers who desire our help in naming fruit should bear in mind that several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruit for naming, these in many cases being unripe and of unattractive form. The difference between varieties of fruit are, in many cases, so trifling that it is necessary that three specimens of each kind should be sent. We can undertake to name only four varieties at a time, and these only when the above directions are observed.

PLANTS AND FLOWERS.

Mildew on Roses (P. Fieian).—Strong soft-soap-water will remove mildew, but unless carefully removed the next day by syringing with soft water, the remedy does as much harm as the disease. Sulphide of potassium is also a good remedy. Use it at the rate of 1 lb. to 1 gallon of water. Apply it with an Abol syringe, and do not forget that the underside of the foliage is the chief part to syringe.

Carnations (Nemo).—The following are six fancy yellow ground varieties: George Druickbank, The Bey, Mrs. Seymour Bulverie, Cardinal Wolsey, Mogul, Brockbank. Of yellow ground Picotees, Mrs. Douglas, Mrs. Alfred Tate, Mrs. Oranfield, Voltaire, Mr. Nigel, and Golden Eagle. Good yellow bells are Britannia, Miss Audrey Campbell, Germania, Mrs. Patrick Campbell. Apply to Mr. Jas. Douglas, Great Hookham, Surrey.

Dwarf border plant from seed (P. S. C. Crumple).—There are the dwarf Tom Thumb forms of Nasturtium, these being more compact. No other plant is comparable with these in their profuse flowering. Double Sweet William, Antirrhinum, pink and red shades of Candytuft, Linum grandiflorum rubrum or red-flowered Flax, and Papaver umbrosum, may be regarded as approaches to what you require.

Salvia patens elba (R. N. Z.).—We have searched through several seed lists, both English and Continental, but cannot find seed of Salvia patens elba offered by anyone. Still, it is a well-known plant, and can be obtained (as plants, not seed) from nurserymen who make a speciality of such subjects, and that, too, at a moderate rate. It is except in colour a counterpart of the typical Salvia patens, which owes its popularity to the hue of its blossom, consequently a white-flowered form does not appear so strongly to growers as the better-known blue kind.
Chrysanthemum growing under glass (Edwin).—The number of flowers to a plant.—No; your

VEGETABLES.

" VEGETABLES IN A SANDY SOIL.

SKILLY there is no place so barren that it cannot, with time and patience, be made into a profitable garden. Less than ten years ago the garden of which I write was an arid sunny patch, enclosed by straggling, untidy heiges and a tumble-down dry stone wall. Now I get from it an abundance of flowers and vegetables. So unfavourable did every condition seem at first, that only a determination to succeed carried me through the disappointments of the first few years. The climate of this part of South Glamorgan is peculiar. The winters are very mild, so that vegetation is often luxuriant all through the year, while in summer weeks of unbroken sunshine succeed each other, it being by no means unusual to have absolutely no rain for as much as six weeks at a time. The soil was pure sand as far down as one could dig, hot and dry; the aspect of the garden southerly, with a slope to east and south; no trees or shade of any kind. Yet the wild sun flowers luxuriated in spite of all, and if garden plants were few, weeds were many. The small-flowered Convolvulus overran everything, and has only yielded to deep digging and patient picking out, piece by piece. It is sometimes stated that in poor shallow soils deep digging is to be avoided, as thereby the thin top layer of soil is buried and only the hungry subsoil left for the crops to make their first roots in. Experience has proved this theory to be a mistaken one in this case. For some years, owing to the local preference for the long-handled shovel instead of the spade, I could not get my garden dug to my liking, and only the top spit was really turned over. However, two years ago I instituted a new regime, and had the whole garden dug two spits deep. It is true that by so doing the little soil on top was exhausted for a fresh layer of pure sand; still I gained a greater depth of soil with marked benefit to the crops, which stand the fierce heat so much better, as they are encouraged to root deeply. Another theory that has stood in the way of cultivation has been the local idea that to weed crops such as Potatoes is undesirable, as the weeds shelter the crops.

As expense has had to be carefully considered in the management of this garden, keenly manuring the ground has been impossible; so every scrap of vegetable waste, leaves, lucern-mowings, Cabbages, anything green, are collected carefully into a sunk pit and left to make leaf-mould for autumn and spring dressing the soil. This makes, without question, the dressing *par excellence* for hot soils. For this reason I grow specially early year an extra quantity of plants of the Cabbage tribe, as they are among the best plants for the purpose. On the same principle, any seed of Peas or Beans sown at the end of the season is sown, and if it fails to come into bearing in November, as the mildness of the climate often allows, they are turned, green, into the soil, and more than replace the nutriment they have taken out. For years it has been almost an

impossibility to grow any summer vegetables, except Glohe Artichokes, as everything—Peas, Beans, Lettuces, Spinach, were burnt crisp and hopeless as soon as the summer heat began. But in this last summer (1901) I have reaped the rewards of patience in excellent crops of Peas and Beans, and four Spinach. A race of Scarlet Runners has been incalculable, bearing profusely in spite of the unusually hot summer. In choosing varieties of Beans, etc., I find the older hardy kinds the best. For some time I tried expensive varieties of Broad Beans, always unsuccessfully, whereas I find the old French Windsor still in some years bear a very fair crop. Salads still remain impossible—Lettuces bolt almost in their seed bed. Still, if they can be watered daily before eight in the morning and mulched up if the wind blows the shifting sandy soil away from their roots, they do fairly well. Even with every care they can have, they are often so wilted by the heat and so flabby that they have to be cut some hours before they are used and put in water. The White Artichokes are incalculable. They get no protection in winter, no special care ever; their leaves flag utterly in the sun, yet they bear profusely. Asparagus, of course, is thoroughly at home, being within a stone's throw of the sea. It is dressed every year with Sea-weed, brought up after the autumn gales, and laid straight on the beds. Sea-kale, too, grows almost without any trouble, and is a reliable crop. These three last-named vegetables were for some time all that I could maintain. Among roots, Carrots are still the best growers, all others do but poorly. Turnips and Jerusalem Artichokes are beginning to be worth growing, but Beet, Turnips, and Parsify will not do any good. Potatoes I grow with fair success, treating them as they are necessarily grown here. A trench is dug and a layer of Sea-weed placed at the bottom, a layer of soil on that, and then the sets on the soil. Many of the cottagers here seem to get good crops, using no other manure, and growing Potatoes year after year in the same ground. Other vegetables grow with varying success, but the general outlines for management of all seem to be, to grow with the object of getting a moderate sized plant rather than a large sappy one; and never to let a crop stand a day after it is past bearing, but turn what is left of it into the ground, again to help to grow its successor.

Coner.

E. S. S.

SUMMER PEAS.

THOSE who trust to the scientific dogma that Pea plants can and do obtain an ample supply of nitroge from the atmosphere for their own requirements, and, therefore, need no application to them of nitrogenous manures, will do well to ignore such notion, especially for Peas that have to carry crops during hot, dry weather. Every gardener who has to maintain a large supply of Peas in the summer knows that his only hope of doing so lies in giving to his Peas not only a deeply-worked soil but an ample dressing of half-decayed manure. That dressing also should, and indeed must, be carried by hand, so as to encourage the roots

to go deep in search of the food and moisture the manure furnishes, and out of the reach of hot sunshine. Manure for summer Peas should be well prepared. It is folly to bury fresh, crude manure, as that is not sufficient decomposed for utilisation by the roots, and is thus, for that crop, practically wasted. Better by far prepare the manure a month beforehand by slaking out from it all long straw, then thoroughly moistening the remainder, using sewage for the purpose, then putting it into a heap to decay, turning it again and well mixing and cutting it some ten days later. A third turning and damping will assist to get the manure into a capital condition to enable it to become quickly soluble and plant-food, whilst its abundant moisture will prove of great help to the Peas when growing.

To apply manure properly, if the Peas be sown in trenches 2 feet wide, the top 12 inches should be thrown out on one side, and the next 12 inches of the bottom soil on the other side, the bottom being then broken up several inches deep with a fork. On to that should be thrown 6 inches of the top soil, and on to this a good dressing of manure, then other 6 inches of soil, some of the bottom soil being added, and a further dressing of manure. That should be well mixed with the soil by forking it in, then add other 6 inches of soil, including some from the sides, and some more manure also mixed with that. Then tread the whole fairly firm. Draw drills with a hoe 4 inches deep, close to each other down the centre of the trench, and sow the Peas in each drill fully 4 inches apart, then cover up. As the trench soil will be a little lower than the surrounding ground, heavy soakings of water may be given until the plants are flowering. Then add after the final watering some soil, and top up with a mulch or dressing of long manure. In that way really grand crops of summer Peas may be obtained in hot, dry weather. It is useless to expect crops when the soil is but merely dry, as roots cannot then go deep and find food or moisture. Such thin sowing as is thus advised proves also to be of exceeding value, as generally Peas suffer severely because of thick sowing, which results in their starvation later, and bloom becomes blim or eaten up by thrips. Milder commonly follows on excessive crowding and root dryness. The effect of the application of moist nitrogenous manures is seen in an early stage of growth, as the roots strike deep in search of it early, and there is a robust leafy growth seen on the plants that is not in evidence when this manure is absent. The early feeding and strong start given to the plants enable them to resist drought all the more freely later in life. Good Marrow Peas, especially such as Prizewinner, Magnolia Bonum, Sharpe's Queen, and The Gladstone, repay this sowing by becoming vigorously branched. Of course, all such Peas should be well stacked, as then they crop so much longer. The few varieties named are all of excellent quality.

A. D.

Burning clay.—I have been burning clay according to the method advocated by "W. S." in last week's GARDENING. I devised a means

of ensuring a sufficient supply of air to the burning mass, while using every available particle of heat generated. When building up the cone I inserted two old earthenware drain-pipes at the bottom of the stack, so that their ends just projected inside the wall of clay, and by this means the air is fed in sufficient quantity to the fire, and also the fire can be stirred up portions of the burnt clay removed. My pipes are about 5 inches inside diameter. The clay may be piled 3 inches or 4 inches over the top of the fire when combustion is over, well started, as the smoke readily finds its way out through the interstices between the lumps, and sufficient air is admitted by the pipes to keep the fire at a bright red heat.—C. M. R.

GROWING EARLY TOMATOES.

In the majority of gardens the first Tomatoes are obtained from plants raised early in the season. In the case of other plants which have been producing fruit throughout the winter, fresh growths can be laid in to provide a serviceable lot of fruit until far on in the season; but it is best not to rely upon these unless they are perfectly clean and healthy and worth keeping. By judicious management fresh plants raised at the time mentioned are not long, under good treatment, in growing to a fruiting size. Very often early Tomatoes are grown in a high and moist temperature; but the growth is so weak that what flowers do form fail to set. There is no danger of the plants becoming ruined through early fruiting, as the earlier fruits induced to form assist in checking exuberant growth and the succeeding blooms set better. What is needed is a strong matured growth, built up by free exposure to sunshine with a warm buoyant atmosphere. It is very annoying to have strong plants capable of carrying a good weight of fruit in a barren state through the blooms failing to set, and with early Tomatoes this is a very frequent occurrence.

It is not during the very early stages that a warm and moist temperature is injurious. The only precaution taken is to keep them from becoming drawn, which is easily prevented by exposing the seedlings to the light on a shelf near the glass. When the plants are allowed to stand pot to pot, even in a light structure, they are very apt to become much etiolated, and the lower leaves, instead of becoming fully developed, are puny with a very yellow cast. In most gardens the earliest fruits are produced from plants growing in pots and boxes, as these can be removed to other available places later on. In those gardens where space is limited sunny places have to be resorted to, to ensure their fruiting satisfactorily. Early Ruby and Conference are admirably adapted for growing in pots and boxes, the growth not being so vigorous as in some of the other sorts.

After having been potted into the 6-inch pots and they have become established, it will have to be decided whether they are to be grown as single stems or with two or three. The single cordon plant will commence to fruit the earliest, and if there is room this system may be adopted. Even with two or three shoots the method is the same. If the plants are repotted into 12-inch pots and other plants are coming in for succession, the leaders should be stopped after two or three bunches of fruit to a shoot unforced. It must not be thought that keeping the plants in the 6-inch pots is an aid to early fruiting, as in this respect they are not in the least more precocious; in fact, in the end they are behind others which have been early potted or boxed. A very dry atmosphere is as much against a free set as an over-moist and close one. By keeping the atmosphere fairly moist the pollen is more potent, and sharply tapping the shoots in the middle of the day is generally sufficient. The two extremes of atmospheric conditions must be guarded against.

The soil can easily be too rich and light and also loose. Where the soil is known to be poor, a little Kamit and superphosphate mixed with

it will greatly assist the plants. On the other hand, good crops may be produced with sound loam and a fourth of pulprised horse manure. The plants delight in a firm root-run, this imparting a fruitful growth, as later on when they need assistance rather late in the form of dilute liquid will prove beneficial. In the early stages of growth Tomatoes should not receive nor do they need an over-rich soil or a poverty-stricken one, both extremes proving injurious to the well-being of the plants.

BROAD BEANS.

BROAD BEANS often receive indifferent culture, some seeming to think almost any position and kind of soil good enough for them. If, however, Beans worth eating are desired, they must be grown in rich, deeply-dug, well-manned soil. Where the soil is poor or shallow, hairy deep-trenches should be formed,

Early Tomatoes.

and a good layer of well rotted manure (placed in the bottom, the soil being then replaced and well trodden. Where the soil is strong and retentive, old Mushroom-bed-manure, with a little artificial manure mixed, is preferable to farmyard-manure, being warmer. Broad Beans are not now often sown in autumn, as, owing to the introduction of earlier varieties, the seed may be sown early in spring, and Beans fit for use obtained at the end of June. Broad Beans are often grown too thickly, with the result that the growth is weak and the produce inferior. The plants should be 6 inches apart in rows 18 inches apart. Isolated rows invariably yield best. Plants raised under glass should be planted in shallow drills and sown

from cold winds by evergreen branches. Where only a limited quantity is grown, it is an easy matter to mulch them with short manure. When the plants are 6 inches high draw a little soil up to them with a hoe to steady them, and when a sufficient number of Beans has formed pinch the points of the growths out, as black-fly often attacks these first. To kill the pest, dip the tops of the plants in Quassia-extract. No vegetable responds so quickly to applications of diluted liquid-manure. Where a constant supply of Beans is required, a sowing should be made every three weeks till the beginning of July, though, where the soil is very light or warm, it is no unwise to sow in the open later than the beginning of June. A north border is then the best place, as there the soil is cool and the plants are easily kept moist. Broad Beans should be gathered when young. If allowed to attain the normal size they become tough and lose quality. Improved Longpod is probably the best early variety; it is very free bearing and of excellent quality. Beck's Gem, a dwarf variety, is indispensable, especially for small gardens. It is a prodigious cropper, and of a beautiful deep green colour. Where ground is scarce this variety may be grown between rows of Gooseberry-trees. Green Windsor, though an old variety, is still very popular, its deep green colour and rich flavour bring much appreciation at table. Johnson's Wonderful Longpod is a heavy cropper, and of good all-round quality. Green Longpod is also an excellent variety.

NON-FUK.

Summer Spinach.—This is in very limited demand generally, yet it is a valuable hot weather salad, because of its antiscorbatic and healthy tendencies. Those who prefer the old Flinders—seed of which is usually sown somewhat thickly in drills, and the plants are not thinned—should sow but a small quantity once a week, as then they have a constant succession for cutting. Those who prefer ample and fine leafage to an upright stem as thickly sown plants give should get seed of the Long Flinders, and sow that on deeply-dug, well-manned soil in drills 15 inches apart. Where the soil is stiff it is wise to sow the seed in shallow drills drawn on slight ridges, as then the plants have natural drainage because thus elevated, yet have all the greater depth of soil to root into. The variety grows strong, and carries large, thick leaves; hence it is useful to thin out the plants to from 6 inches to 9 inches apart in the rows.—A. D.

Spinach Beet.—When a difficulty is experienced in growing the Winter or Prickly-seeded Spinach, a good breadth of the above should be sown in the autumn. This is not only hardy, but is not in the least affected by the damp weather of the winter months; consequently, the plants are vigorous and afford a fair supply of leaves early in the year, when the true or Winter Spinach is making a hard struggle for existence. A warm border or sheltered piece of ground should be selected for the autumn sowing; not that the plants will suffer if raised in a more exposed position, but because they may experience all the warmth possible, in order that growth may be as continuous as circumstances will permit. The large fleshy leaves go much further in cooking than do those of the ordinary Spinach, consequently more produce can be taken from a given piece of ground. With regard to the cooking qualities of Spinach Beet, some hold the opinion that it is inferior to Spinach proper, while others assert that it is equally as good. However this may be, the fact remains that it is a hardy and easily-grown substitute for Spinach, and I recommend those who fail in wintering the latter successfully to give it a trial if they have not hitherto done so. Two things are essential in its culture: the one is to well manure the ground previous to sowing, and the other is to see that the seed-bed is made firm by treading the surface evenly previous to sowing. The drills may be drawn from 15 inches to 18 inches asunder and about 2 inches deep. Drop two or three seeds at intervals, or about 1 foot apart, and close in the drills with the fret and rake the surface smooth. Should the seed germinate irregularly, the gaps may be made good by sowing in the "clommings," as Spinach Beet transplants easily.—A. W.

PLANTS AND FLOWERS.

ACHIMENES.

AMONGST tuberous-rooted plants none are more beautiful for growing in baskets or pans than are the Achimenes, the richness of the blossoms and their freedom making them useful for the warm greenhouse, needing, however, less heat than many imagine—indeed, one may say that their summer treatment is identical with that given an all-round greenhouse collection of plants, except that they will not stand exposure to draughts. The numerous hybrid sorts embrace many shades of crimson and blue, white and scarlet, orange and purple, and when seen to advantage—i.e., hanging from the rafters in a warm house—are a sight not soon forgotten, as they are somewhat out of the ordinary line of basket plants. By a little arrangement in starting the tubers at different intervals, one may have a continuance of

and pots, or growing them in pans. Being of a pendulous habit, they look well hanging from shelves, and make charming subjects for blooming in early autumn. Associated with Achimenes and other plants of a like character in a house, *Torencias* are very beautiful when in bloom, and embrace several colours, as will be seen, including *T. Fournieri* (violet and lilac), *T. F. grandiflora alba* (white), *T. Baillonii* (yellow and purple).—LEAUCRST.

BOUVDARIAS.

ONE of the prettiest flowering plants for greenhouse and table decoration is the Bouvardia. These who have old specimens will find on them in the half ripened wood plenty of material for propagating. Cuttings should be selected a few inches long, and planted firmly in pans of loam, with which have been mixed leaf-mould and sand, placing the pans in a propagator. If it is not convenient to do this

plant is it, I think, more essential that this should be observed, for if the wood be not ripe flowering shoots will not be numerous. Knowing this, one must see that for two or three months at least the plants enjoy as much sun shine and air as possible, and, bearing this in mind, it is advisable to remove them to a frame outside towards July, keeping the sashes off, but taking care that the aspect is a sunny one. As the best flowers proceed from the ripened wood, so every opportunity should be taken to ensure this during the period they are in the open frames. This may also be further helped by giving each plant plenty of room, rather standing them on the garden walk than attempting to crowd a dozen plants into a frame where half that number could be better accommodated.

FEEDING.—One must also not forget stimulants, and whatever is used should be given in a weak condition and often. Whilst one must make much of air and sunshine in the maturing of the wood, Bouvardias must not be left out-of-doors too long, and accordingly in September their transfer to the house again will become needful. In the warmth of the house one should be able to have blooms in November, and for winter flowering, that popular sort *B. leirantha*, whose scarlet blooms make a house bright, must not be forgotten. President Garfield (double pink) and Alfred Neuner (double white) are varieties, too, that are worth the attention of those who are on the look-out for winter-flowering plants. As Bouvardias are practically in flower all the winter, notably *B. leirantha*, and afford sprays of blossoms that may be used for personal adornment, attention to them now is specially recommended.

DEBRY.

POT MIGNONETTE.

MIGNONETTE is always acceptable, but never more so than in the winter and spring months, when it cannot be had out-of-doors. Only rarely and in dry weather does Mignonette smell so sweet out-of-doors as it does when well-grown under glass, where the flowers can be kept dry and grossness of growth is checked. To have a good stock for cutting all through the winter and spring months requires some forethought and care, for though the plants must be kept growing, very little fire-heat checks the development of the flower-spikes and causes them to become blind, while it forces new shoots to develop from just under the spikes, only to become blind in their turn. Any attempt to force the plants on is sure to result in failure, but if grown along steadily fine spikes may be had all through the dull season.

Growers for market bear the palm for producing good pot Mignonette all the year round, and only in rare cases do we see anything at all equal to their productions in private gardens. This, no doubt, is partly owing to the unsuitability of the large houses common in private gardens and the mixed collections of plants which have usually to be grown in them. Fancy triennial specimen plants, such as standards or trellis-trained, are of very little use for producing spikes for cutting, the best plants for this purpose being grown three in a 6-inch or one in a 4½-inch pot. Sow the seed directly into the pots in which the plants are to flower, as repotting, unless done with great care, often gives the plants a check from which they never recover. If the proper soil is used, the pots well drained, and watering carefully carried out, there is no fear of the soil becoming sour or stagnant. The best soil is half loam and a quarter each of well-dried and decayed cow-manure and lime-rubble from some old hair plaster if possible. The loam should be at least six months stacked, free from common worms, which would soon block the drainage, and from wireworms and other grubs. Lime in some form is an absolute necessity, and no kind seems so acceptable to the plants as that from old plaster. Two sowings—one made about the third week in July and the other a month later—will be sufficient for winter and early spring flowering. Of varieties, I like Miles' Hybrid Spiral best of all, though Garraway's White is also an excellent kind. These two branch out and give useful spikes in addition to the main growths. Much of the credit of this article is due to all who like

Achimenes growing in pot.

loom. In commencing with them one or two joints are worth enjoining, and the first is as to time. February is soon enough to put the tubers in heat, and if it is decided to grow them in pots or pans, one should recollect that perfect drainage is essential, and so are clean pots and crocks. Soil made up of well-rotted kaim, sharp sand, brown fibrous peat, or, failing the latter, leaf-mould, with a little decayed cow-manure added, will suit Achimenes admirably, placing immediately around the tubers a portion of sand. After potting, or placing in baskets, let them be put in a house where a minimum heat of 65 degs. is maintained, and encourage a humid atmosphere. W. F.

Torencias.—*Torencias* can be reckoned among the best of our greenhouse annuals, and those who are in doubt as to what to grow in their hanging baskets cannot do better than at once sow seed in heat in pans of light soil, transplanting the young seedlings into baskets

then cuttings should be inserted round the edges of a pot, covering it with a bell-glass, letting it have the advantage of the warmest position in the house. Some bottom-heat, if at all possible, should be given, as this will aid matters considerably. As soon as the cuttings have struck and growth is proceeding they should be potted off singly, using a similar compost to that just described, keeping the surroundings moist, and so pushing them on until ready again for a further shift, until the blooming pots are reached, for which size 6-inch pots will be found ample. When the young plants have reached a height of several inches the leader should be stopped, as this will induce side shoots to form, and so result in a bushy habit. A second pinching of the shoots should, if needed, be made a little later.

RIPENING THE WOOD.—One of the points that requires watching in connection with the propagation of Bouvardias for winter and spring flowering is the ripening of the wood. This is

very large spikes, but it is not nearly so useful as the others, as it does not branch freely, and is practically over when the leading spikes are just their best.

When the plants are flowering freely a little weak manure-water will be helpful to them, but it requires more care in its application to *Mignonette* than to most things. Soot is sometimes recommended for mixing with the soil, but is scarcely necessary, and should be left out unless it has been formed from good coals and stood for some considerable time before using. New or limed soot burns the roots and injures the plants. —T.

NOTES AND REPLIES.

Cyclamen.—Of all our winter blossoms, none are more service to the small grower than *Cyclamens*. To see to what a high standard of perfection these have been brought, one has only to compare present day varieties with those grown a decade or two ago to realise what progress has been made. —W. F.

Sauromatum guttatum.—The botanical name of the tuber sold under the name of "Monarch of the East," which is referred to in your issue of April 5th under the heading of "Notes and Replies," is *Sauromatum guttatum*. It is an arbol. I have one which is growing very rapidly without either soil or water. —GEORGE ARMSTRONG BARNETT.

Cyclamens from seed.—As in your issue of March 13th you rather seem to imply that you do not expect *Cyclamens* to flower in a year from seed, I send you a photo of some *Cyclamens* from seed, sown Feb., 1901, first flower open Jan. 15th, 1902. One of these plants has two pure white flowers, two pink, and two white with pink stripes. —R. B. BARNES, *Launceston*.

[The photograph sent showed five plants, carrying on an average seven flowers and buds each. Two plants had as many as eleven flowers, the foliage strong and healthy, and quite biding the tops of the pots.—Ed.]

Growing bulbs without soil and water.—A question was recently asked in GARDENING about the *Arum cornutum*. I have grown it for years, and at this moment have a root or bulb in flower on my table. It has had neither soil nor water, but in January it was put near the glass in my Orchid house. The bloom is about 10 inches high, and the spathe is spotted yellow and purple. It has a very offensive smell when first expanded. The bulb has no roots; it sends up spotted foliage after the flower is withered, in shape like the wild *Arum*. —MRS. TAYLOR.

Double Chinese Primulas.—Some of the most successful growers of these plants I have seen of late are in the Leatherhead district, Surrey. I have seen noble plants in 7-inch pots measuring 15 inches over in full bloom in November, the varieties being chiefly *Marehioness of Exeter*, white; *A. F. Barron*, pink; *Lucy Hillier*, and others. One grower increases his plants by dropping the pots in early spring into others a size larger, placing fine sandy soil about the base of the leaves, then slightly layering the side-growths into it, and soon has well-rooted plants. These were then severed from the parent plants with a sharp knife, got into large 60-sized pots, stood in a gentle warmth to establish them, then shifted on until they were finally got into 7-inch pots, in which they flowered nicely all the winter. Good plants gave a wealth of bloom, which could be gathered and wired freely. —A. D.

Tuberose.—These chaste and fragrant flowers are not so difficult to grow as many imagine. Many failures in their culture are due to giving them too much heat in the early stages of growth; this causes the plants to go blind. I wanted to flower in winter, the bulbs must be potted as early in autumn as possible. Use 6-inch pots and a light, rich compost, and place one bulb in each pot. Pot firmly—the firmer the better. Place them in a temperature of from 55 degs. to 60 degs., and plunge the pots in the rim in a bed of Cocoa-nut-fibre or leaves, and give a bottom-heat of 70 degs. to 75 degs. Give no water till growth commences, then water liberally till the flower-buds are formed, when they may be removed to a warm greenhouse or conservatory, and less water given. For autumn blooming pot the bulbs in 6-inch pots in March or April, and plunge the pots 6 inches above their rims in Cocoa-nut-fibre, leaf-mould, or fine ashes, in a cool pit or frame. When the foliage makes its appearance remove them and plunge them under a south wall, keeping them well supplied with water, also well syringed to ward off red-spider. Remove them to the greenhouse as the flower-buds appear. Dry roots may also be started

in light, rich soil, in warm positions out-of-doors. These, if taken up in autumn, potted, and placed in a temperature of 50 degs., will afford a supply of bloom for several months. The double American Pearl is the best variety. —C.

Repotting greenhouse Ferns.—Where greenhouse Ferns need repotting, and the matter has been put off, no further delay should take place, but as new growth has now commenced the work should be taken in hand. Maidenhairs, for instance, that are so frequently in demand, should be repotted at once, shaking away any superfluous compost and replanting them in leaf-mould and mellow loam, with a small portion of coarse silver-sand. After the shift it will greatly help their progress if for a few weeks they can be placed in a pit, where additional warmth and moisture will make up for lost time. March, as a rule, is the best time for the work to be done, but carried out in the way proposed at once they will soon "pick up." —W. F.

Freessias.—Will you kindly give a hint on the cultivation of these? Also say if the bulbs are of any use for another year? I have had two pots in an unheated conservatory, but only one good bloom out of about 12 bulbs. —A. H., *Bournemouth*.

[Keep your bulbs in a light place until the foliage begins to show signs of decay, then gradually withhold water, eventually laying the pots on their sides, either at the foot of a wall or under the greenhouse stage. During the last week in August shake the bulbs out, potting the smaller ones, seven or eight, into a pot 3 inches in diameter, or, where there is a quantity, into small pans. The large flowering bulbs should be put, five in a pot, into a pot 5 inches in diameter, or larger masses may be formed by using a larger pot, with, of course, a greater number of bulbs. A suitable compost is two parts loam to one part each of decayed manure and leaf-mould, adding to this a liberal sprinkling of silver-sand. The upper part of the bulb should be about 3-inch below the surface of the soil, and when potted they may be covered with Cocoa-fibre and placed in a cold-frame. As autumn advances, remove to the greenhouse and place in a good light position. When growing freely occasional doses of liquid-manure will be very beneficial.]

Schizanthus Wisetonensis.—This is a wonderfully free-blooming variety of this beautiful class of annual, among which that named *S. retusa* has for so many years been cultivated in pots for greenhouse and conservatory decoration by many growers. It is of easy culture, and anyone possessing a greenhouse would experience no difficulty whatever in growing it if the following details are observed. The best time to sow the seed to have plants in flower at this date is the third week in August. The seed will then germinate without the aid of any warmth beyond that afforded by a cold-frame, and if sown thinly, nice dwarf plants will result. When large enough, pot them into small 60-sized pots, these being quite large enough, and place them close up to the light. By the end of September or early in October they should be removed to a shelf in the greenhouse, and be afforded just sufficient water to keep them in a healthy condition without unduly promoting growth. Early in January give them a shift into 48-sized pots, using a compost of two-thirds loam, one-third leaf-mould, with enough silver-sand added to keep the whole open, and return them again to the shelf or a similar light and airy position. This latter is very essential, otherwise once the plants begin to grow freely they will draw and become lanky and be spoiled if far away from the light. About the end of February the plants will, if all has gone well, be about a foot or 15 inches in height, and showing an abundance of flower-buds. If there is room for them to stand on the shelf until the flowers are about to open, all the better, but as soon as the blossoms begin to develop stand the plants on the stage among the other plants, or in the conservatory, when they will make a fine show for several weeks. As soon as the flower-buds become prominent, a little weak manure-water will prove of the greatest assistance, for the flowers being produced, as they are, in such great profusion, a very great strain on the energies of the plants is a natural result, and should therefore be guarded against. —A. W.

WHAT TO DO WITH PERENNIALS. (REPLY TO "ENQUIRER.")

You open up a question of very considerable, as well as general importance, the gist of which is: What is the best means of reviving old-established perennials that are now re-appearing through the soil? The enquiry comes from the Thames Valley district, a district, by the way, we are well acquainted with, and just as well do we know of the many vicissitudes ever going on in such a district, with all the ill-consequences of a low-lying area, and of fog or other such undesirable things. Frequently too much of the soil is very light, and the surface soil being shallow and overlying a deep bed of good gravel and sand, the drainage is excessive, thus leaving the soil dry beyond all conception. It is in circumstances such as these that many perennials require to be replanted much more frequently than would otherwise be the case, for the soil itself is generally poor and hungry in the extreme. No doubt this is much of the trouble in which "Enquirer" finds himself at the present moment, and we deal with the subject freely because of its general import to many readers; secondly, by reason of its seasonableness; and, thirdly, because we know full well that by continued neglect the plants dwindle down to very small flowerless scraps. "Enquirer" particularises such things as *Panicles*, *Phloxes*, *Hollyhocks*, *Doronicums*, *Irises*, *Asters*, *Rudbeckias*, and *Clematis*, but, without knowing what kind the last is, we are unable to supply the required information. Taking the others as they stand, the *Panicles* and *Hollyhocks* can only be lightly forked around and well mulched with rotten dung, or a good dressing may be dug lightly in between the plants. The *Phloxes* and *Asters* require to be treated similarly, or divided and replanted at once. Avoid large pieces, and select the outer, stronger portions for replanting. In both instances a far better result is secured by planting single stems, such usually having three or four eyes at the base. Three or five such pieces planted back will give an effect in the coming autumn far finer than the original old clump, and all the spikes will be good because of the ample room for development. A clump of five pieces should be set out with a diameter, roughly, of 2 feet. Such *Asters* as *Amellus* and *acris* would require more space by reason of a more bushy growth. *Rudbeckias* and *Doronicums* may be treated in the same way. *Irises* that have flowered twice in the same position should be lifted, pulled to pieces, retaining only the current year's (that is, that of 1901) rhizome, and discard all the old back ones as worthless. The young rhizome with growth attached is the flowering piece, and these make goodly patches like the *Phloxes*, etc. *Pyrethrums* and *Delphiniums* that have made about 4 inches of new foliage may be lifted, broken up very carefully by inserting the prong of a small hand-fork into the root stock, and giving a gentle outward wrench to separate them. Both groups require some care, and frequently it is best to wash the clumps free of soil before attempting the division. This will show the direction of the crown tuft and chief roots, then by inserting the prong about the centre of the clump, piercing it to half way through, you will soon find the working. If the halves are too large divide again. In these more difficult plants you should start operations on a less valuable sort and note the result. In neither case should division be necessary unless the plants have flowered two seasons in the same position. Up to this age a good mulch and light forking over of the border should suffice. All *Sundflowers* of the *H. multiflorus* class and those belonging to *H. rigidus* should be replanted each year to get the finest flowers. In the *H. rigidus* set only the growing point of the rhizome and its few roots are required to be retained. *Tritomas* or *Red-hot Pokers* need not be replanted but every third year, while any plants producing many stems, like *Phloxes*, and numerous crowns too, are subjects for frequent replanting, or, at least, every two years. Deep digging and free manuring with firm planting should go hand-in-hand. March and April are excellent for the purpose. *Spiraeas* and *Day Lilies* should not be disturbed, but dig in plenty of manure around them, and afford water in plenty.

SNOWDROPS AT DUNBOYNE.

Airborne frequently naturalised in England and in Scotland, Hooker says it is hardly so in Ireland, adding that it is possible wild in Hereford and Denbigh. Its general distribution in Europe is from Holland southwards, and in Western Asia. It is a matter of history that Snowdrops are very abundant in the Crimea, as a good many roots were found in the trenches dug there in 1854, and sent or brought home by the officers on active service there at or after that time. The Crimean Snowdrop (*Galanthus plicatus*) is a very large and distinct kind, but some fine forms of the common Snowdrop (*G. nivalis*) are also found here. One of the most robust and handsome of these is the Strathin Snowdrop (*G. n. grandis*), the original roots of this having been found by the late Lord Clrinn in the Tehermag Valley, and it has luxuriated beside the silver Liffey at Strathin ever since, or for

which our present example is one of the most beautiful. The illustration is an object lesson as to bulb planting near to the trunks or holes of deciduous trees, and shows that a regular dotting of bulbs at equal distances over large areas of lawn is not the best, the most economical, or the most picturesque way of arranging them. The view here given shows clearly and effectively that a focus spot or principal group is necessary in every picture, and that a few bulbs grouped irregularly near dark and velvety-green tree-roots gain immensely by the force of contrast, and finally that all due sense of a right and natural perspective is thus preserved. E. W. B.

GOOD GARDEN LILIES.

THE Lily that is generally the first to expand its blossoms is *L. pyrenaicum*. Its chrome-yellow petals, spotted with purple-black, are set off with orange-scarle anthers that give

beautiful flower than this exists when in perfect health and freshness. In many cases, however, it is, unfortunately, attacked by an insidious disease, which renders it a pitiable sight. Where the disease is bad it is best to lift the bulbs and place them in flowers of sulphur, leaving them a month in the sulphur until they are thoroughly dry, and then replanting, with a sprinkling of kailit around the bulbs at a few inches' distance. The Orange Lily (*L. croceum*) is an old cottage favourite, though perhaps not so extensively grown in these gardens as is the last-named. It is of hardy constitution, and often attains a height of over 6 feet when left alone for several years. *L. excelsum* or *testaceum* is a beautiful Lily of a soft buff shade, said to be a cross between *L. exaltatum* and *L. chalcidonicum*. It is of easy culture, and is rarely troubled with disease. *L. chalcidonicum* is the brightest of all Lilies, its flowers being of a vivid vermilion hue, while they remain in beauty for a considerable time owing to the

Snowdrops at the Grove, Dunboyne. From a photograph by Miss Mabel Gaisford.

nearly fifty years. The Snowdrop may not be a real native of Ireland, not even naturalised there to the same extent as in England, but the fact remains that it luxuriates in Irish gardens by the thousand, and is more often found near to dismantled walls "where once a garden smiled." Our present illustration is from a very beautiful photograph taken in The Grove at Dunboyne, Co. Meath. It shows how charmingly the Snowdrops grow there clustered among the velvety bushes on the old tree-roots, their snowy whiteness contrasted with grass and other herbage, and with the lichen-covered boles of the trees. Our picture is by Miss Gaisford, a lady who to a love of horticulture adds great artistic skill in plant portraiture with the camera. Residing, as Miss Gaisford does, at The Grove, Dunboyne, Co. Meath, and being in close proximity to the noblest gardens at Carton, to Binnwood, Strathin, and many other good gardens, we have received from her some very welcome and excellent garden pictures from time to time of

the flower a handsome appearance. The blooms are, however, possessed of a most disagreeable odour, and if grown in any quantity render the part of the garden they inhabit almost unbearable. *L. pyrenaicum* is generally closely followed by *L. Thunbergianum* or *elegans*, of which a fine lot of varieties is now in commerce, amongst the best being Alice Wilson, lemon-yellow; Orange Queen, bright orange; Wilsoni, apricot-yellow; Horsmanni, mahogany-crimson; and *marinorum aureum*, deep yellow with crimson spots. Some of these varieties are far later in flowering than the type. *L. flavum* or *umbellatum* is also represented by many varieties, some of which have been raised by crossing with *L. Thunbergianum*. The following are good: *aurantiacum*, orange; *Clith* of Gohl, golden-yellow; *platinum*, orange-amber with yellow band up each petal; *Sensation*, pure yellow with scarlet spots; and *incomparable*, dark crimson spotted black. The peerless *Muldoan* Lily (*L. vanthoureni*) is well known to all, and no more

solidity of the petals. *L. Szovitzianum* is a most attractive Lily, being clear yellow in colour, the petals in some cases spotted with numerous tiny black specks and in others free from them. *L. Martagon* is best known by its white variety, *L. Martagon album*, which is a charming flower. Two dark-flowered varieties are *L. M. dalmaticum* and *L. M. d. Cutoni*, the latter of which is almost black. *Martagens* resent disturbance, and rarely flower well for a year or two after removal. The new *L. sulphureum*, formerly called *Wallichianum superbum*, gives promise of being of easy culture. It is a most elegant and refined Lily, with large, widespreading, white flowers tinted yellow inside, and grows about 6 feet in height. *L. Henryi*, sometimes styled the yellow *scicoum*, is another new introduction, and has already proved its hardiness and value. It is an exceptionally robust grower, reaching a height of 10 feet, and bearing twenty or more flowers of a rich orange-yellow. *L. giganteum* is a noble Lily from the Himalayas, that under favour-

able conditions attains a height of from 10 feet to 14 feet. It should be planted in a bed rich in humus, at least 3 feet in depth, and should receive a mulching of thoroughly rotten hot-bed manure every autumn. A slanted position is preferable for this Lily, but if well looked after it will also succeed in the open border. In procuring bulbs of *L. giganteum*, medium-sized ones should be ordered in preference to the largest, since if the latter flower the first year they will not have time to become established before the flower-stalk is thrown up, and this will be a relatively poor one, probably not more than 6 feet in height. In wintering smaller bulbs, the time of wintering will necessarily be lengthened, but the flower-stems when they are at length thrown up will be typical. Seed sown will produce flowering bulbs in eight years. After flowering, the main bulb of *L. giganteum* entirely disappears, leaving around the base of the stalk a few off-sets, which usually take from three to four years to attain flowering size. *L. Hansonii* is a pretty Lily of deep yellow tint, heavily spotted with black. It rarely exceeds 3 feet in height. *L. tigrinum* is the latest of the Lilies to bloom, flowering in August and September. The two best varieties are *L. tigrinum Fortunei* and *L. l. splendens*. The former sometimes attains a height of 7 feet, and bears forty to fifty flowers of an orange-pink hue, spotted with deep purple. The latter is of deeper colour and bears larger flowers, but is of less vigorous habit.

All the foregoing Lilies, except *L. giganteum*, whose wants have been detailed, do well in ordinary garden soil mixed with road-grit and leaf-mould. *L. Ifualobotti*, a very handsome Lily, with upright-tinted flowers blushed with lake, likes a compost of fibrous manure and leaf-mould in equal parts, and the Swamp Lilies (*L. cyathense*, *L. parviflorum*, and *L. superbum*) succeed best in peat, which should be kept moist during hot weather. The three last are very graceful Lilies, and well repay any trouble taken in studying their wants in the matters of soil and water. The charming little *L. rubellum*, with deep pink flowers, does best in a bank of light soil where the drainage is perfect. *L. unicum*, *L. speciosum*, *L. Brownii*, and *L. longiflorum*, in their numerous varieties, do well in some gardens, but refuse to become established in others. All have remarkably handsome blooms, and, should they fail to succeed, the display may be kept up by annual purchases, for they rarely fail to flower their first season. In planting Lilies care should be taken to group them naturally. Partial shade is beneficial, and a site where this is provided by large trees, at a sufficient distance to prevent the soil of the Lily bed being robbed by their roots, is an ideal one, since the surrounding trees provide adequate shade and shelter from strong winds, both of which are beneficial in Lily culture. S. W. F.

BEGONIAS IN THE FLOWER GARDEN.
(Reply to "Sera.")

BEGONIAS intended for the flower garden are often started too early in the year and in too much heat, and if not potted into large pots they become root-bound and stunted. Consider April the best time for starting the bulbs, and a temperature of 55 degs. quite high enough. They may be potted in small pots, in good loamy soil and a little manure and leaf-mould, or placed in shallow boxes in Cocoanut-fibre or leaf-mould. It is astonishing how quickly the bulbs root into these. Those in boxes must have plenty of room for the plants will become drawn and wanky. A light position is also essential, and as soon as growth commences as much air as the state of the weather will allow must be given. A close atmosphere soon draws the plants up. The more sun the plants have the better, and this should be husbanded by closing the house early on fine afternoons. When growing freely the plants may be assisted with weak liquid-manure, and the foliage should be syringed twice daily. Should any flowers appear when the plants are small they must be picked off. At the end of May place them in a frame, hardening them by gradual exposure to the air. Begonias require a fairly rich loamy soil, but beware of digging in rich farmyard manure, as it encourages the plants to grow too strongly. If animal manure is used it should be dug in

deeply early in the year. The best stimulant consists of old Mushroom bed manure, with a small quantity of artificial manure added. Leaf-mould and wood-ashes are also excellent. The beginning of June is a good time to plant out Begonias, and a fairly sunny position should be chosen. If the plants are strong allow a distance of 9 inches between them, and after planting mulch them with Cocoanut-fibre or short manure. Begonias delight in abundance of moisture at the roots, and in dry summers a good watering every ten days will not be too much. Weak liquid-manure may also be freely given. J.

NOTES AND REPLIES.

Alum-water for Hydrangeas.—Some time back you said in your paper that alum and water would cause Hydrangeas to come blue. I should be obliged if you would kindly tell me how much alum to the water and how much and how often to water? In my flower garden, just opposite, the same Hydrangea was a lovely blue, here it has been pink. J. Smalley, Saltwood, Hants, Kent.

Dwarf pink Nasturtium.—Will someone give me the name of a dwarf Nasturtium of a pink or rose shade suitable for growing in a border? Must bloom all summer.—CENTURY.

[Ruby King is the nearest approach in colour to what you require, but we cannot answer for its flowering all the summer. Much of this depends upon treatment, soil, and other things. Many kinds, however, are quite profuse in their flowering.]

Water Lilies in tubs. Will you kindly answer the following questions in the next issue of GARDENING? 1. Where can I get the new hardy tubed Water Lilies? 2. How can I grow them in barrels sunk in the ground—how deep should the barrel be, will the ordinary wooden bottom do, and how should the barrel be planted? 3. Has this method of growing them been successful? I have no pond, so it is the only way I could manage.—J. M. M. K.

[Water Lilies do well in half tubs buried in the turf and half filled with heavy soil and water. On lawns the tub or half tub might be sunk level with the surface, thus giving the leaves and flowers of the Water Lilies the appearance of growing out of the ground. Of course the strong-growing varieties of the *Mylæna* type are too vigorous for this mode of culture, but there are many of the less strong-growing kinds that answer well treated thus. Apply to Amos Perry, Winchmore-hill, London, N.]

Cheapsness of spring flowers.—To-day is the first day of spring as I write, and I have been buying out-flowers. Bunches of double *Daffodils*, of "Butter-and-eggs," twelve blooms to the bunch, fresh and beautiful, are retailed at one penny per bunch, *Anemones* likewise, and sprays of fragrant *Freesias* at the same price. Violets for many a day have been hawked in our streets at the same modest sum. What would be without flowers in their rooms? I look around mine, and forget for the moment that winter has only just left us.—LEADER.

Annual Larkspurs.—Where facilities do not exist for growing perennial Larkspurs, then some of the annual sorts should be given a trial. The seed should be sown during the present month in some sheltered border, subsequently transplanting them to the places where they are wanted to bloom. Anyone having experienced a difficulty in getting other plants to flower on dry borders will, I am sure, be pleased with Larkspurs. There are several distinct sorts of varying heights and colours—the Stock-flowered, Ranunculus-flowered, and dwarf Rock-rose-flowered being amongst the best.—W. F.

Tall dwarf Wallflowers for early flowering.—If Mr. Cook would procure and sow seed of all variety of Wallflowers named Earliest of All early in June, he would, I venture to think, experience no difficulty in having an abundance of these delightfully fragrant flowers for cutting from the autumn and onwards through the winter months, should such prove mild. This variety has not failed to yield great quantities of flowers with us since the autumn. They are now going over, but the fact of its being such an early blossoming and free-flowering variety cannot be too widely known.—A. W.

A pair of Tropæolums.—*Tropæolums* as distinct in point of culture as it is possible to be, but both possessing flowers that are decidedly pretty and freely borne, are *T. speciosum* and *T. Jarratti*. The first named has certain peruliarities which have to be taken into account, and one of them is that, as a rule, it will not grow in places where much sun can

reach it, but where other climbers sometimes refuse to grow at all—viz., on an east or north east wall—there *speciosum* will often thrive and bloom most profusely. *Jarratti*, though a tuberous-rooted *Tropæolum* like *speciosum*, is best seen in a greenhouse, where one may count on its scarlet and yellow blossoms in early summer. *Jarratti* may be planted at once in the house, and *speciosum* out-of-doors in April. Both are handsome climbers in their respective positions.—DERBY.

Salvia patens alba.—I am surprised to learn that in one catalogue seed of this plant. Possibly its existence is too little known generally. A few years since, when at Malvern, I saw it growing freely, and sowing about West Malvern, and Mr. Fidler kindly gave me some seeds. These I gave to a friend and asked him to raise plants, with the view, first, of testing adherence to character and, second, if favourable, of raising a stock of seed. He found all the plants flowered white, as the parents did, and was enabled to send the *Salvia* fresh. Where the blue form and the white one are planted together the effect is very pleasing. All the plants have tuberous or fleshy roots, and these can be wintered, then induced to break freely in the spring, and furnish a plentiful stock of cuttings.—A. D.

The French Marigold.—In April, exhibitors of this favorite flower generally sow their seed, and prepare the beds for the plants. In many cases out of ten these beds are dressed with manure, which, I consider, from an exhibitor's point of view, so much waste of time, many of the blooms, owing to the rich soil, coming of a dark brown colour, which, of course, is useless for a show stand. A poor soil suits the French Marigold admirably, because it induces the plants to throw yellow flowers, and what is better than to feed gradually until the blooms become perfectly striped and of the proper depth. The finest French Marigolds I ever had were grown on an old Strawberry-bed which had been trenched deeply, and which had got up manure of any kind. The Marigolds were given liquid cow-manure when coming into bloom.—D. G. McIVER, *Bridge of Weir, N.B.*

The Night-scented Stock (*Hesperis tristis*).—In reply to your remark on my inquiry about *Malthida*, I have been put off by seedsmen with seeds of *Malthida bicoloris*, which is not the plant I seek. I was advised to apply to Messrs. Thomson and Morgan, of Ipswich, as a firm likely to supply old-fashioned flowers. In a reply I received from Mr. Thomson, he said the *Malthida odoratissima* was the plant I was seeking, and that he only knew it from an illustration in a book, and would gladly learn where he could get it. Probably he thought it might be obtained from some historical garden. The plant I seek was common fifty years or so ago in good gardens. It had long, very narrow glaucous leaves about 2 inches to 3 inches long, and a hoary-green plant, which grew in sprays, and began to smell almost punctually at 3 o'clock p.m. I found a plant in a nursery at Dovercourt, but cannot now learn the name and address. I kept it till in a change of residence in 1896 it was lost. SALE.

[We think it is *Hesperis tristis* you are seeking. Try for it under that name.—Ed.]

The Eastern Christmas Rose (*Helianthus orientalis* var.).—The old and true Christmas Rose was always vastly more popular in gardens than this, the later-flowering and more varietal Christmas Rose. But this is a very beautiful plant, less capricious, hardier, and more rigorous in nearly all its ways than *H. viger*. Flowering early in spring, and often, as we see this year, at the end of winter, it has a little more chance of a fine hour now and then, and it comes with all those delightful things that make the spring so charming to those who cultivate the early flowers. On the coast and sheltered spots everywhere better results are obtained. There are a great number of names given to forms of this species, but they may be all grouped under the general name. There is a striking family likeness between them, the most distinct being the white, which are very pretty at this time of year. The plant does not seem so particular about soil as the Christmas Rose, and we have had strong examples in ground where the Christmas Rose is very slow

and doubtful. These are ground plants forming evergreen borders, and they never show their great beauty and value until they are several years undisturbed. They are admirable for borders near walls and places we want to keep quiet, and yet fresh and furnished at all times—that is to say, where the ground is not broken up twice a year for bedding out.

What to do with old Hyacinth bulbs.—Many gardeners, myself included, have always been in the habit, after these have finished blooming, of planting them in a border, there to furnish a supply of bloom for a few years. This is a very good plan, and should always be done by those who require an abundance of cut bloom, but a few may be used otherwise. Last December I took several thousands of the bulbs which had flowered the previous spring, and planted them thickly in a back pit, just covering the bulbs with fine soil. In the pit I had a hot-water pipe along the back, which, however, I did not use unless in severe frost. After planting, I spread a few mats on the glass until some growth had been made, afterwards giving them all the light and air possible. The result has exceeded my

expectations. Every bulb has thrown a good spike, and in many cases two, and I have been cutting sheaves of bloom since March 5. The only attention given was in ventilation, no water having been required since the bulbs were put in. The aspect of the pit was due south. D. H. McI., *Beddy of Blair, N.B.*

Plants for north border (A. W.).—There are many things suitable for such a border; indeed, the shade would be helpful to a few things, particularly to *Spiraea vanuta*, *S. palmata*, *S. Aruncus*. These are moisture-loving subjects usually considered, but with strong soil and partial shade do quite well. Among other things you could now plant are Oriental Poppies, *Alstroemeria aurea*, *Galtonia canalicata*, Irises of the Flag section, *Lathyrus latifolius* and *albus*, *Tritonias*, Day Lilies, *Helianthus pumilus* (2 feet), *H. autumnale* (3 feet), *H. nudiflorum*, *crispum* flaked (5 feet); *Aster Amellus*, *A. aeris*, *A. brigitulatus*, and a set of *A. Nova-Anglie*; *Delphinium formosum*, and say half a dozen others in variety. Peonies would be excellent, and you had best make a note of these for planting in September. It is far too late to plant them now. *Stenactis scariosa*, *Rudbeckia purpurea*, *R. Newmanni*, *Sunflowers*, *Lilium tigrinum*, *L. t. E. P.*

ETHIONEMAS.

This genus comprises some half-dozen or more species, though it is, perhaps, doubtful whether all could be found under cultivation in England at the present time. In general habit of growth there are a certain sub-shrubby character of the more important kinds, and a rather woolly stem at base. In cultivation these

plants in it or upon it. I have only tried two species of this genus in walls of any kind, and the behaviour of the plants was an experience well worth gaining, albeit it is now some years since.

In all cases where possible these plants must be raised from seed. For the rock garden the seeds may be sown a few in a pot, the seedlings being afterwards transferred bodily to the required position. For the wall garden there is nothing to equal sowing the seeds in the chinks of the brickwork or stonework. Small seedling plants may be inserted in the joints also, but there is a fear of injuring the roots, and in this instance it is important to avoid this. In the accompanying picture is given one of the most important kinds—viz.,

E. carmiflorum. As may be gathered from the illustration, there is much of the ordinary Camlytist in the round-headed racemes and not a little in the growth. The blossoms are rosy-lilac, and the linear and glaucous leaves are each about an inch long. This is a true perennial in the positions indicated, but on level ground in rich soil it is not so permanent. A native of Asia Minor, flowering in early summer.

E. grandiflorum.—This is also an important species, and differs from the above chiefly in the elongated racemes, that incline to columnar in outline, and in the ovate-oblong glaucous leaves. The warm rose flowers are freely produced and rather crowded upon the racemes, the flowering beginning in May and continuing for some weeks, when strong examples are found. Native of Mount Lebanon.

E. pychellum is also showy and good, and though counted a distinct species comes very close to *E. cordifolium*.

The other species which are more strictly annual are *E. saxatile*, *E. monospermum*, and *E. Busbaumii*. E. J.

CHRYSANTHEMUMS.

HOW TO TREAT PLANTS TO FLOWER LATE.

(REPLY TO "AN AMATEUR, BIRMINGHAM.")

To reply satisfactorily to your questions is no easy matter, as you desire to have all your plants in flower over a period of three months. You cannot do better however than allow the plants of the early and semi-early sorts to flower from terminal buds. Mme. C. Desgrange, G. Wernig, Mme. Marie Masse, Rycroft Glory, and La Vierge are five popular sorts which will give a free display of blossoms in October if the plants are grown on to the terminal buds. As you specially state you want plenty of flowers of the five sorts already named, the plants should be left to develop their branching shoots naturally. All you need do when the terminal-buds appear is to slightly thin them out, leaving a goodly number of the larger and better shaped buds. In the case of November-flowering plants, the treatment must be different, as you say you want from eight to fifteen flowers on each plant, and the individual blooms are to be about 8 inches across. We very much doubt whether you will be successful in getting so many large blooms as the number named above. In any case, you should adopt the following method of culture. Assuming that your plants are now well grown and sturdy, pinch out the point of each growth, and as the resulting shoots form in the axils of the leaves grow on three or four of the strongest. About the end of June pinch these shoots in turn and again take up three or four of the best-looking of the resulting shoots, and secure the first buds subsequently developing. By these means you should have no difficulty in obtaining at least a dozen good blooms on each plant. Of the varieties in your list suited to this method the following may be relied on:

Ethionema cordifolium.

plants must have ample drainage. Anything tending to the opposite conditions will quickly show itself, and the falling of the leaves is a sure sign of this over-wetness or of root inactivity in some form. The best position one can give is one fully exposed to the sun, and, if possible, situated upon a slope or trailing over some ledge of rock where warmth and ample dryness at the root exist. Where these conditions prevail the plants may be given quite a deep bed of earth to root into. Loamy soil, freely intermingled with old mortar, limestone chippings, or the like, will assist in the direction indicated, and, provided no manure of a crude nature enters into the composition of the soil, there is no reason for failure, with the best kinds at least. Not a few have endeavoured to grow these elegant little plants mainly in peaty soils, but success is rarely assured by these means. At the same time, I would prefer to employ peat rather freely if the soil were inclined to be heavy. Light, sandy, and therefore, poor soils are the best for this class as a whole. Such is the dry-loving nature of these plants that I would unhesitatingly plant any of them in the chinks of rockwork, in any old crumbling or newly-built wall, provided this latter had been erected with a view to growing

the terminal buds. As you specially state you want plenty of flowers of the five sorts already named, the plants should be left to develop their branching shoots naturally. All you need do when the terminal-buds appear is to slightly thin them out, leaving a goodly number of the larger and better shaped buds. In the case of November-flowering plants, the treatment must be different, as you say you want from eight to fifteen flowers on each plant, and the individual blooms are to be about 8 inches across. We very much doubt whether you will be successful in getting so many large blooms as the number named above. In any case, you should adopt the following method of culture. Assuming that your plants are now well grown and sturdy, pinch out the point of each growth, and as the resulting shoots form in the axils of the leaves grow on three or four of the strongest. About the end of June pinch these shoots in turn and again take up three or four of the best-looking of the resulting shoots, and secure the first buds subsequently developing. By these means you should have no difficulty in obtaining at least a dozen good blooms on each plant. Of the varieties in your list suited to this method the following may be relied on:

Vivian Morel, Chas. Davis, Lady Hanham, Mrs. J. Ritsen (the foregoing are all members of one family), Modesto, Souvenir le Petite Amie, Pride of Ryecroft, Mrs. J. Bryant, Lord Cromer, Nicom, and Phoebe. The following three sorts should be grown freely and flowered from terminal buds: Ryecroft Glory (Jap.), Miss Mary Anderson, and Miss Rose (singles). They should be pinched at once, and each succeeding 8 inches of growth treated in like manner, giving the last pinching at the end of June. For those to flower in December you should pinch the plants at once, taking up three shoots from this point, pinch again in the early days of June, and for the last time pinch the plants about the middle to the third week in July. The resulting shoots should give you the number of buds you desire, and the subsequent blooms should be in good form by the middle of December or earlier. Vivian Morel and Chas. Davis being the earliest of those in your late list, should be pinched last, say about July 20th.

STOPPING AND TIMING.

(REPLY TO "DULLY" AND "J. A.")

For exhibition, the following dates for pinching the points out of your plants should interest:

Name.	When to pinch the plant.	Which bud to retain.
Miss Alice Byron	April 10th	Second crown
Calcutta No.	April 10th	Second crown
Mrs. Barkley	Now	Second crown
Mrs. Lombard	Natural break	Second crown
Anabelle	Natural break	First crown
Le Grand Dragon	Now	Second crown
Miss. Carrot	2nd week April	Second crown
Mr. T. Carrington	Now	Second crown
Mrs. J. Lewis	Natural break	Second crown
Phoebe	Natural break	Second crown
Sou. de Petite Amie	Natural break	Any buds in late August
Rose Wynne	2nd week April	Second crown
Elthorne Beauty	2nd week April	Second crown
Henry Stone	May 21st	First crown
Golden Mate	May 10th	First crown
W. H. Lincoln	Natural break	Any buds in late August
Good Gracious	May 21st	First crown
Mons. Chonon de Lecke	Natural break	Any buds in late August
Florence Davis	May 21st	First crown
Bonnie Dimple (inc.)	Now	Second crown
Miss. Ed. Boyer (inc.)	Now	Second crown
J. Bunyat (Jap. Amie)	Now	Second crown
Sou. des Negros (Jap. Amie)	About April 10th	Second crown

(REPLY TO "AMATEUR.")

You do not say whether you are growing your plants with the object of exhibiting the blooms next autumn, but in giving our reply we have assumed that such is the case. Birmingham being a good representative Midland centre, we have timed the following varieties for the show held in that town at the usual period in November:—

Japanese.

Name.	When to pinch.	Which bud to retain.
Cecil Wray	1st week April	Second crown
Sou. de Petite Amie	Mid-April	Second crown
Mons. G. Molin	Mid-April	Second crown
Boule d'Or (Cult. No.)	April 10th	Second crown
Robt. Powell	April, 1st crown	Second crown
N.C.S. Jubilee	Mid-April	Second crown
Lord Brooke	May 7th	First crown
Hon. W. F. D. Smith	At once	Second crown
Lady Ridgway	At once	Second crown
La Triumphant	Mid-April	Second crown
Nicom	May 12th	First crown
Anabelle	May 20th	First crown
Maryot	Natural break	Terminal buds
Miss. Hicon	April 10th	Second crown
Source d'Or	Natural break	Terminal buds
W. H. Lincoln	Natural break	Any buds in late August
President Nonin	1st week April	Second crown
Edith Tabor	May 20th	First crown
President Borel	At once	Second crown
Sunstone	At once	Second crown
Rose Wynne	April 10th	Second crown
Royal Sovereign	May 15th	First crown
Phoebe	April 10th	Second crown
Mrs. E. A. Hill	At once	Second crown
Mons. W. Holmes	Natural break	Terminal buds
Fashion	Natural break	Terminal buds

Incurved.

Chas. H. Curtis	May 20th	First crown
Golden Empress of India	April 10th	Second crown
Empress of India	April 10th	Second crown
J. Agate	At once	Second crown
Globe d'Or	1st week April	Second crown
Queen of England	April 10th	Second crown
Beverly	Natural break	Terminal buds

The other varieties in your list being early-

flowering and decorative varieties, should be grown freely, and terminal buds retained. You ought to read the general article dealing with "Stopping and Bud-retaining," in our issue of Feb. 8, p. 649.

OUTDOOR CHRYSANTHEMUMS.

REPLY to a paragraph in GARDENING ILLUSTRATED from "Townsmen" on outdoor Chrysanthemums, which he says he leaves out in his garden all winter, etc. I should be very much obliged by his giving me further particulars as to treatment of the old plants in April? Are they divided up, or the suckers only taken to form new plants? Also what is then done with the young or ill-bred stock? Any information on this subject will be appreciated.—M. WATSON.

[Already I have begun to divide my old plants, and the practice I adopt is to lift them, cut away as many of the most promising suckers with roots attached as I can, and plant them by themselves. Any suckers that may get broken I trim, put them in pots of sand and loam, and keep them in a cold-frame near the glass until roots have formed. Other plants that have several stems are pulled to pieces and each inserted in a fresh place in the border, and these seldom fail to do well. Suckers, of course, have more vitality, and are to be preferred to old stumps. After what has been written about outdoor Chrysanthemums and the simple culture they entail to secure quantities of flowers, one would think that everyone would grow them; but this is not so, for comparatively few have them in their gardens. With many, Chrysanthemums are still associated with glasshouses, and they overlook altogether varieties that for weeks, and even months, precede the November, or show sorts. Last October I cut a clothes-basket full of blooms and sent them to a side of work; they were quickly disposed of, and several who purchased them expressed surprise that flowers so beautiful could have been grown out-of-doors, inclining to the belief that a greenhouse for Chrysanthemums was indispensable.

As mentioned in my previous note on this subject, early-flowering Chrysanthemums need no glass protection whatever, as, with a little straw, manure, or Bracken, they pass through the severest winters. I cut away the old stems as soon as they have died down, and earth up the soil with a little manure round the crowns and seldom lose any. Any who have not as yet grown the early-flowering sorts should purchase plants next month, bed them out in the borders, stop them once or twice in the season, feed them a little in August and September, and expect to have flowers. They will bloom, and well, too. For the benefit of new growers I give a list of varieties for supplying a succession of flowers, and would add that, for a town garden where other herbarious things sometimes die off after a few years, Chrysanthemums are sure to give the greatest amount of satisfaction. Where early autumn flowers are wanted in quantity for cutting, few can compare with those under notice, for the lasting propensity of the Chrysanthemums is admitted by all who grow them. Two of my breeders serve me well. One, being on the south side of the garden, consequently supplies the earliest bloom; and the other on the north side furnishes blossoms of the same varieties ten days or a fortnight later. It is, however, on my south borders where my stock plants are wintered for the most part.

LARGE FLOWERING VARIETIES.—Mrs. Bartoll, pale primrose, August; Sam Barlow, pink, August; Harvest Home, bronzy-red, tipped gold, August. Louis Lenoire, rosy-bronze, Mme. Musse, lilac-mauve, Mme. Desgrange, white, tinted blush, bloom from August to October. The following are at their best in September: Alfred Fleuret, rosy-lilac, Lady Fitzwygram, white, Edie Wright, white, shaded mauve, Annie Bowman, rose, Coval Queen, coral, De la Tuille, variegated, Mons. Dupuis, orange, Mrs. Geo. Hill, primrose, Mrs. Squire, white, A. Lejeune, rosy-lilac, Claret Bell, claret-crimson, A. Chausson, orange and yellow. October sees these in full bloom: James Salter, pink, Lady Selborne, white, Mme. de Gabarier, crimson, Medusa, old gold, Mme. E. Povrette, rose, Hortulanus, rosy-salmon, Ivonne Miref, carnine, Crimson Queen, crimson, Mons. W. Holmes, crimson, Golden reverse, Roi de Precoce, crimson, King

globe, deepest crimson, Pride of the Market, yellow.

EARLY-FLOWERING POMROSE.—Flowering in September: L'Ami Comberchet, primrose, La Vierge, white, Mrs. Selby, blush, Rose Wells, pink, Little Boh, crimson, and Fred Felt, red-lilac. August and September: St. Crouts, lilac, Canari, pale yellow, Blushing Bride, rosy-lilac, Anastasia, purple, Mr. Selby, blush, Piercy's Seedling, orange-yellow, Lyon, rosy-purple, Crimson Precoce, crimson, Mrs. Childingford, white, Precoce, yellow, Alice Butcher, red, flower in October. Strathmeath, rosy-pink, blooms during September and October.

I never dislike the early-flowering sorts, choosing rather to have a profusion of blossoms to the few, as with me the object is to grow for cutting, and a few sprays, on which I can count a dozen or so blossoms, can be taken from each plant and scarcely missed; whereas, if depending to any extent were practised, this could not be. Some of my old plants, especially Piercy's Seedling, Mme. Musse, Mme. Desgrange, Gustave Gimmerwall, Harvest Home, Crimson Queen, Mons. W. Holmes, etc., were almost 3 feet across and carried hundreds of blossoms. Nearly all of them have been propagated in the open. TOWNSMAN.

Pinching early-flowering Chrysanthemums.—I had a few of the earliest summer-flowering Chrysanthemums. If I pinch them, does it make them flower earlier, or are they later than if they were allowed to break away naturally?—A. H.

[If we understand you rightly, you wish to know whether by pinching your plants of the earliest summer-flowering kinds they are made to blossom earlier or later than they would if left to make a "break" naturally. If the plants be pinched before they make a natural break—i.e., while they are small plants represented by a single stem—their period of flowering may be expedited thereby. The object of pinching these plants is to make them branch or "break" out into new shoots, and the earlier this branching takes place the earlier will the plants come into blossom, because their buds are developed earlier in consequence. So far north as Dunblavin, N.B., we know that many of the sorts which bloom in the south quite satisfactorily in October are of little use to growers situated as you are, and for this reason pinching some of the slightly later sorts may bring them within the period you desire.]

ROOM AND WINDOW.

WALLFLOWERS IN WINDOW-BOXES AND POTS.

Few plants are more suitable for window-boxes in spring or for growing in pots for the decoration of the conservatory than Wallflowers; but in order to ensure dwarf, bushy plants good culture must be given. In the first place, the young plants must be well thinned out in the seed-bed, and, as soon as large enough, transplanted 9 inches apart into deeply dug ground, well enriched with thoroughly decomposed cow or horse-manure. If the soil is rather heavy, so much the better, as then the plants can be taken up with good balls of soil in autumn. It is a good plan to water them with soft manure in summer. Copious waterings will be necessary from time to time. In October the plants should be taken up carefully and potted or placed in window-boxes, as the case may be. Some well rotted manure should be placed on the drainage in the boxes, and the latter nearly filled with good leamy soil. The Wallflowers may be planted fairly close together, and the soil made firm round the roots. Planting completed, give a good watering, and apply a mulch of old Mushroom-bed-manure. If the weather is dry, the plants will require several good waterings. Eight-inch pots are best for Wallflowers. When potting them, ram the soil fairly round the roots, and leave a good margin for water, as they require a plentiful supply of it in spring. When potted, place the plants in a cold-frame, plunging the pots to the rims in ashes, Cocoa-tin-lime, or leaf-mould. Protection can then be given in severe weather. If the plants are removed to a light, airy house or pit in January, and a temperature of 50 degs. given, they will flower in March. Keep them

near the glass, and assist them frequently with weak liquid manure. Harbinger, Bellevue, Castle Yellow, and Blood Red are good varieties for pots. J.

LILIES OF THE VALLEY LOOSELY ARRANGED.

SAFETY in arrangement as it pertains to flowers is not nearly enough adopted. Some would be horrified if they had to depend upon such a common thing as a tumbler wherein to arrange Lilies of the Valley. If, however, the tumbler be a plain one and not too wide at the top, it will make an excellent receptacle for them. In its use there is one most essential advantage that often escapes notice. It is that of being able to employ plenty of water, without which it is next to impossible to keep the spikes fresh for any length of time, more particularly in the case of forced ones. These latter, having been brought on so rapidly,

but not so much as to injure the foot-stalks, and then to bind damp Moss around the stems, these afterwards being dipped in tepid water before packing is finally completed. By taking these precautions the flowers will be found much fresher. It ought also to be said that it is not merely the time taken in transit, but there is also the time lost between arrival and arrangement, and that possibly after the flowers have been unpacked and then left exposed. I am led to make these remarks now, as it is the season when more forced flowers are used than at any other time. It is simply waste all round to spoil flowers at such times after their production has cost considerably trouble to the gardener. S.

EVERLASTING BLOSSOMS IN THE HOUSE.

AMONG some of the blossoms which we are accustomed to call "everlastings," are beautiful

how, after blooming, the peculiar Thistle-like heads may be cut for mixing with Grasses, etc. Xeranthemums are not grown so frequently as one would expect them to be, considering that they are hardy annuals, and are useful for making up winter bouquets. I have mentioned Gypsophila paniculata—the other member of the family is deserving of special mention—viz., G. elegans, which being a hardy annual is easily raised from seed sown in the open. Statice Suworowi has flowers of a rose colour, keeps well when cut, but is, I think, being gradually superseded by the white form—viz., meana, or, as it is commonly called, Silver Cloud—a variety which bears branching stems of what are tritely termed "cloud-like blossoms." It is a perennial which should be in all collections of hardy plants. Globe Thistles (Echinops) are, I imagine, fairly well known, their round heads of prickly light being blue in colour, and forming fit companions to the Eryngiums for making up for winter baskets and bouquets. Acaelinums are most effective hardy annuals. They are not much grown by amateurs, but having in view their use for winter they are worth more attention. Perhaps it is left to a half hardy annual to be regarded as the most popular "everlasting." I refer, of course, to the Helichrysums. One knows how by sowing seed in boxes in March or April in a greenhouse or frame, then jerking them off, and subsequently planting them out of doors about the end of May, or sowing in the open air in April, it is easy to obtain great quantities of rose-looking blossoms of white, yellow, crimson, and rose. Like other similar everlasting flowers, Helichrysums should be cut when partly expanded, as with drying they open further, and if not cut until fully matured the seedy centres will drop. Amongst greenhouse annuals, one of the prettiest of the early-flowering varieties is the Rhodanthe. Most people who know little of flowers, or their names, recognize each spring the pots of delicate looking rosy-pink and white blossoms, which find such a ready sale, and are called by the not inappropriate title of "Everlasting Daisies." The culture of the Rhodanthes is exceedingly simple. Sow the seed now and during the next few weeks for succession, in shallow pans or boxes of light soil in a warm house, transplant them into pots when well into their second leaf in batches of fifteen to twenty in a 5-inch or 6-inch pot, in soil of light loam, with which finely sifted leaf-mould and coarse sand have been incorporated, well draining the pots and keeping them on a shelf near the light, watering only when needed. They are charming for a house-window or for table decoration. They may be grown by anyone who can raise them in heat, but do not require a heated structure afterwards; in fact, a cooler temperature will suit them better. Liable to damp off when young from over much moisture, it is wiser to err on the side of dryness than to use the water-pot too frequently. These, too, tender annuals though they be, may be gathered when partly opened, and add interest to baskets or vases of dried flowers and trusses in winter days, when other blossoms are scarce. WOODS-STWICK.

Lilies of the Valley arranged loosely in a glass

require a deal of sustenance. When, therefore, a good depth of water can be had it is all the better for them, this being further improved upon by using the stems at full length. In the case of the forced single crowns it is even possible to take the crowns and a few roots also. Thus employed, there is every prospect of the spikes continuing much fresher than would otherwise be the case. If looked at in a sensible light it will at once be seen that forced flowers of any kind require more water to keep them fresh than those which open naturally. This, therefore, should be the aim of all who have to arrange forced flowers. Another essential point to observe is not to expose forced flowers to the draught. For instance, if stood near to an open window the inevitable must soon follow as a matter of course.

When sending forced Lilies of the Valley any distance, the time taken in transit being sufficiently long to cause them to suffer, by far the best plan is to tie them up in bunches tightly,

when growing in the borders in July and August, it is really on account of their value in the house in the darkest days of the winter that they are most appreciated. To my mind it matters little whether the garden is large or small, as in every place where flowers are regarded with favour, a corner should be set apart for those that add a little brightness to rooms at this time of the year, and the one who has no greenhouse especially will do well to hear in mind flowers that may be dried off, so to speak, and yet retain their colours months after the plants themselves have died. Some blossoms possess a delicate gauze-like appearance, like Gypsophila paniculata and Statice, that are worth the little trouble they demand for the lightness and grace they add when freshly gathered to mix with Sweet Peas and Poppies and other fragile flowers, to say nothing of their use now when quite dry. The origin, everyone knows the value of the Sea Bonnet (Eryngium) for winter decoration

GARDEN PESTS AND FRIENDS.

Worms at roots of Lettuces.—I shall be glad to know the name of the worms enclosed in tin sent herewith? They are in great numbers among the roots of Lettuces, some of which they have wholly destroyed in this way. I suppose there is no remedy but hand-picking? —DREA.

[The grubs injuring your Lettuces are those of a fly, probably the St. Mark's fly. See answer to Miss Holt, in this week's issue.—G. S. S.]

Chrysalis in soil.—Enclosed in the box herewith you will find a chrysalis which I picked out of some ground which I was turning over this morning. I shall be glad if you will tell me the name of it.—DARFORD.

[The caterpillar that you found in the ground is that, I believe, of the "Dart-moth" (Agrotis segetum), but it was in such a shrivelled condition when it reached me that I cannot be certain. These caterpillars are most injurious to the roots of many different kinds of plants, and when met with should always be destroyed. They have an annoying habit of eating through the tap-root of one plant and then going on and treating another in the same way. Unfortunately, they are very common.—G. S. S.]

Insects in flower-border.—I would be obliged if you would tell me what the grubs in the accompanying box are? They were found just under the surface in flower-border, about fifty in one place.—M. ITOR.

[The grubs you sent are those of a two-winged fly belonging to the genus *Bibio*, probably *B. Marci*, the well-known St. Mark's-fly, so called from its generally making its appearance about St. Mark's-day (April 25); but they may be those of another species. The St. Mark's-fly is a black and very hairy fly, which does not fly very well. They may often be found in pairs settling on plants or on the ground. They generally appear in considerable numbers for a day or two, and then seem to vanish altogether. These grubs are undoubtedly injurious to the roots of plants, but I cannot recommend any other way of destroying them but picking them out of the soil. You cannot water the whole garden with an insecticide, and even if you could it is very doubtful if many would be killed.—(C. S. S.)

Woodlice in frames and houses.—My garden,inery, and frames have been infested with woodlice ever since I came here. I have tried boiling water, also dusting with quicklime, but they still increase. Is gas-lime (diluted) injurious? I can get it near here. Does it injure plants, even if washed off soon? Is there anything better, but not very dear? Some of my *Seakale* crowns have had the shoots eaten by lice and small grubs, so I have removed the pots, dusted with slaked lime, lightly covered again with stable-manure without pots, and propose to gradually cover as it grows. Is this right in the circumstances?—A. V. BYLER.

[I do not think that you would do any good by watering the soil with "gas-liquor," or any other insecticide, and I am uncertain what effect it would have on the plants. The boiling water should be poured down by the edge of the soil where it touches the wood or brick-work of the frame—it will kill any woodlice that it comes into contact with. If you lay down bricks, tiles, or pieces of shite on the earth, you will find that the pests will congregate under them, and in this way you may catch large numbers of them. They may be poisoned with phosphorus paste spread on pieces of bread or mixed with *Burley-meal*. They may sometimes be driven away by the free use of *Pyrethrum* insect-powder, or they may be caught by folding up strips of brown paper partly smeared inside with beer or treacle or sugar, and laying them about so that the woodlice can hide in them. You are doing quite right in dusting the lime round your *Seakale* crowns, this being the only available remedy.—(C. S. S.)

ROSES.

ROSE SOLEIL D'OR.

THOSE who do not already possess this fine novelty should make a point of doing so. I am much pleased with it, and consider it a great gain. In the forcing-house the variety has been very conspicuous, the golden-yellow of its medium-sized blossoms having a very cheerful effect during the dull months. In some respects it resembles one of the parents—*Persian Yellow*. The roundish buds are similar, but the flowers are larger, and, moreover, the reddish tint upon the centre petals gives this Rose a most unique appearance. Then, again, the perfume is delightful. The raiser claims for this Rose that it is perpetual. I hope it may be so. It will make an excellent garden variety, as the growths that produce the flowers are not straggling, but quite short and compact, so that every blossom is well displayed. Until we obtain a really good golden-yellow Tea Rose of a hardy nature *Soleil d'Or* will be in much demand, as it is just the colour wanting. There are very many golden-yellow Roses, but only one or two sturdy enough to plant in large quantities for massing. I hope Monsieur Pernet-Ducher will give us still more distinct breaks, such as he has obtained with *Soleil d'Or*. There is a danger, I think, now-a-days that we may get too many Teas and Hybrid Teas. Let us have another turn at the Hybrid Perpetuals, and endeavour to instil into this hardy tribe the autumn-blooming qualities of the true Teas. We want their rich crimson colours and their sweet fragrance. Far too many of recent inventions have no perfume whatever.

Rosa.

Rose Marechal Niel falling.—I bought a Marechal Niel Rose about two months ago. It was in a 7-inch pot when I bought it, and I made a bed formed with

bricks about 2 feet square. I placed some broken bones at the bottom, then some rough turf, and then filled it up with leaf-mould, with a small sprinkling of guano, and placed it in a lean-to, a new growth of canes, and all the new wood goes the same way. Would you kindly oblige by telling me the cause of it so doing? It is in greenhouse in temperature of from 55 degs. to 60 degs.—A. MATHER.

[It is not a good plan to use leaf-mould for Roses unless mixed with loam. There are various fungi lurking among the decayed leaves that might be the cause of the blackened growths enclosed. We are, however, rather inclined to believe that the guano is the cause. We do not know why you gave the plant guano in its present stage, when there were no active roots to utilise it. When planting out this fine Rose under glass good loam is the best soil for the purpose. Mix with it a little sand and short manure, and you will not improve in this mixture. When the plant shows its flower-buds is quite time enough to give artificial manure. We should advise you to remove some of the leaf-soil immediately around the ball of earth, taking care not to disturb any roots, then replace with some loam in which a handful or two of sand has been mixed. Before putting in the loam make sure the ball of earth containing the roots is well watered. Sometimes if this is dry when planted no amount of water given afterwards will penetrate it. It is always well to stand the plant in a vessel of water a few minutes prior to planting out. We mention this because this may be the cause of the blackened shoots.]

TREES AND SHRUBS.

FORCED SHRUBS.

SOME of these will now have gone out of flower, but, nevertheless, do not despise the plants or treat them badly, for with good care they will do a good turn again in one way or another. *Azalea mollis* and *A. pontica* also are valuable for forcing. This is well known, but the fact that the plants may be retained in pots from year to year does not appear to be understood. They will not, except in a few cases, be of any great service to force next spring, but in two years they will yield an abundant crop of bloom. They will flower in many cases as freely as newly-potted ones, with one distinct advantage—that the flowers do not drop before expanding; that is sometimes the case with those freshly potted. When the plants are well established the flowers are of greater substance and last longer; at the same time the wood is longer-jointed, which is another advantage, as longer stems are thereby secured. As soon as all the flower is out the plants are pruned a bit into shape and still kept in a growing atmosphere, getting them into a cool-house in a few weeks, and thence out of doors. Dwarf Charles X. Lilacs when cut are close pruned, but these will be put outside sooner than the Azaleas. *Guchler* Roses should be treated the same as the Lilacs. *Dentzia gracilis* when cut should be grown on us in the case of *Julian* Azaleas; thus treated this useful shrub will flower every year. *Spiraea confusa* should be treated the same as the foregoing *Dentzia*, save that it will do quite as well in a little less warmth.

The plants just named, to, if used in conservatory decoration, should be brought back again into warmth as soon as out of flower, the knife being used where essential to keep them within compass and also compact. In a few weeks sufficient growth will have been made for them to be shifted into cooler houses before being finally stood out-of-doors early in May. Whilst advising pot culture for *Azalea mollis*, I am driven to the fact that they can be successfully treated by the planting-out process, making better growth without doubt; but then those of us who are not fortunate enough to possess suitable soil will do much better by adhering to the pot system. After planting out, when again relifted, they will take much larger pots; this should be considered. *Pink Rhododendrons* (hardy kinds) can now be brought on into flower much more successfully than earlier in the season. As the buds swell they should be freely syringed, giving at the same time a liberal supply at the roots. *Hydrangea pinnatifida* (after last pruning) may now be started in batches in a moderate heat, keeping the plants as near the glass as possible.

FRUIT.

PROTECTING PEACHES WHILST IN BLOOM.

Most gardeners are aware of the advantages of protecting Peach and Nectarine-trees whilst in bloom, but the mode of doing this has to be gauged according to the ways and means at command. The worst form of protection is that where it has to be kept over the trees permanently the whole time they are in bloom, and very often much beyond this period if the weather should be cold and unseasonable. By far the least objectionable of fixed coverings is fish netting; light and air can penetrate through this, but not so those close-woven fabrics which are often used for the purpose. When these are fixed over the trees they are kept in a state of semi-darkness, and the flowers as they open, on account of the subdued light, are greatly weakened, and the fructifying organs correspondingly so. Under such treatment only weak flowers can be expected, and although a fair proportion of them may set, yet on account of the imperfect state of the fertilising, the small fruits fail to swell. Not only does this close covering conduce to the above evil, but it also tends to blister on the leaves. This cannot be termed a disease, but it is brought about by cold wind acting upon the young and tender foliage, and is accelerated more or less by sudden exposure after a lengthened period of close covering.

My Peach wall is surmounted with a glass coping, or rather a framework, into which are fixed squares of glass just previous to the trees coming into bloom. Some people look upon this as an expensive luxury, but it has paid for itself over and over again. Along the front are hung lengths of a warm, net-like covering. The strands are not close together, but sufficiently far enough apart to allow of a fair amount of light reaching the trees if the weather was so cold that they could not be drawn up. It is fixed to the outer edge of the coping, along which runs a strong wire, and on to which the covering is hung. When let down it is fixed in close to the wall at the bottom. It is astonishing the amount of cold it keeps out, and it has turned several degrees of frost whilst the trees were in bloom. The coping keeps the flowers dry, and with this assured, it takes a severe frost to cause the least injury. At the time the trees are in bloom, and if the day has been such that they could be uncovered, the blinds are pulled down about 5 p.m., and unless the night should be mild enough to allow of their being pulled up early in the morning, wait until about 9 a.m. before pulling the blinds up. During cold days the covering should be kept down.

To prevent blister, the same course of procedure is adopted if the weather is likely to be unfavourable. Trees which have been completely covered and which, after the petals are shed, are exposed are sure to suffer from blister. If it could be managed, the uncovering should be gradual, and if a cold spell is likely to intervene, the trees should be covered again for the time being.

II.

MULCHING FRUIT-TREES.

THE mulching of fruit-trees is not always carried out as it should be. Many persons put on a thick covering of manure over the surface of established trees in the autumn, leaving it there until decomposition has entirely taken place. This is a great mistake and a practice likely to lead to bad results in many cases. Mulching is really carried out to conserve the moisture in the soil. Another object in mulching is to encourage surface roots, it being an acknowledged fact that a cool, moist condition is the most favourable to this. When the soil is baked dry on the surface the roots seem to shrink from such unfavourable conditions, and dive deeper in quest of that moisture which is denied them on the surface. Those persons who practise mulching of established fruit-trees in the autumn and winter cannot have any other reason for so doing than that of adding stimulating food to the trees. Mulching is not the best way to carry this out; the process of absorption is too slow to be efficacious. The evil of autumn and winter mulchings is great; the presence the chief factor towards success

is absent—that of the sun warming the roots and soil in the early spring and summer. Established trees, such as Peaches on walls, or, indeed, any kind, do not need assistance from mulching until the crop of fruit is assured; then this addition of food is useful to help to swell the fruit. The

MATERIALS FOR MULCHING are not always well chosen. The constituent portions of the soil should determine in some measure the kind of manure that is best suited to give the greatest assistance to the tree. A heavy soil, which is naturally much colder than a light one owing to its greater retention of moisture, should not have the kind of manure laid on the surface that is calculated to render it still colder. I allude to cow-manure, which is heavy and "chuser" in its composition, therefore not calculated to suit heavy soil. Partly-decayed horse manure, with a fair amount of short straw amongst it, is the best kind of manure for strong land, especially if a good quantity of wood-ashes can be added to it. Light sandy soils are benefited by the addition of cow-manure. In the case of newly-planted trees it is the accepted rule in all well-managed gardens to apply some partly-decayed manure to the surface soil directly the trees are planted, the object being two-fold: to protect the roots from frost during winter, and to maintain the soil in a moist state during the summer months. This not only minimises the labour in applying water to the roots during very dry weather, but keeps the soil in a better state than when artificial watering is resorted to. The evil of mulching is that the manure robs the roots and soil of the benefit that should accrue from the sun shining upon them at a certain time of the year. Many persons do not think of this; if they do, they do not take the trouble to remedy the evil. If the mulching was removed the first week in May or earlier, according to the state of the weather, being simply drawn off to one side and then allowed to remain for at least three weeks, when it could be replaced provided hot and dry weather necessitated its employment for maintaining the soil in a moist state, better results would follow. Trees that are planted high—as they should be in soil which is not all heavy or wet—are much more likely to suffer from drought than those which have their roots deeper in the soil. If anyone will try the experiment of removing the mulching from newly-planted Apple-trees and allow it to remain on others all the year without a break, he will quickly see the difference in the growth of the trees under the two methods. Where the removal of the mulching is neglected the growth is poor as compared with the other plan.

NOTES AND REPLIES.

Manuring orchard.—I have an orchard facing S.E. Grass covered, light soil. I give it each year a good dressing of tarant manure, and the trees are out twice. Could you please tell me of a suitable artificial manure to use, weight to the rod, and probable cost? Thanking you in anticipation.—H. LAVINE.

[If yours is an old orchard, and roots are deep and far away, surface manuring does not render the trees and fruit the same good service that is done when the trees are lushy or dwarf, and on surface-rooting stocks, such as the Paradise for Apples, and Quince for Pears. Were not the orchard on Grass, so that you could deeply bury or fork in the manure, then the roots would more benefit. As it is, the Grass gets most of the manure feeding. Of artificial manure, a good dressing is basic slag, kainit, sulphate of ammonia, 2 lb. of each mixed per rod. These vary in price, but range from 12s. 6d. to 15s. per cwt.]

Disbudding and stopping Apricots.

In most instances the time has arrived for starting the work of disbudding and stopping. On old trees first thin out any thickets of shoots there may be, leaving only enough to just clothe the branches with fruiting spurs. Many of these reserved ought also to be stopped at the fourth or fifth leaf, but where there is good space for laying in young wood, reserve shoots, well placed for this purpose, to their full length. It is the younger branches that derive the greatest benefit from the warmth of the walls, and which also produce the heaviest crops of fine fruit. Young trees will also require to be attended to, thinning out the young shoots, stopping some of those reserved

in order to promote an early and strong growth of leading shoots, or any intended to be laid in between the leaders. Extra strong shoots are apt to develop at the expense of their weaker neighbours and become gross. It is advisable to pull off such robbers, their places being better filled with medium-sized growths.

Fruit-tree stocks.—"A. D." in his interesting communication in a recent issue of GARDENING, alludes to Bourré d'Annalis as being an excellent variety for serving as a medium for double grafting weak growing Pears upon. Having had but a little experience in the matter of the double grafting of Pears with the view of imparting a stronger constitution to varieties that are interiorly weak growers, but which possess good flavour, I can quite agree with all he says with regard to this particular variety as being one of the best on which to work scions, or to lay those kinds it is desired or necessary to improve. Bourré d'Annalis succeeds so well on the Quince that there is not the slightest fear of either bud or graft falling when worked upon it. It is, as "A. D." points out, just the few inches of the stem that are retained for either inserting the land or working the scion upon that exert such a wonderful influence on these constitutionally weak growing kinds, and it is only those who have experimented in this direction that can realise what a marked effect it has in imparting a more robust constitution to them. Double grafting also improves flavour in some cases, even when the matter of growth of the variety is not at fault, and from a series of trials made, and which covered a period of several years, I arrived at the conclusion that a very great deal may be done towards improving the flavour of many varieties that are not by any means first-rate. I would strongly urge those of your readers who may feel inclined to experiment to study "A. D.'s" notes, and to act accordingly.—A. W.

GARDEN WORK.

Conservatory.—The spring is the season when some extra attention must be given to training. In the old days gardeners often devoted a good deal of time and used up a large number of stakes in training their plants; but a different order of things prevails now, and less training is done, and fewer stakes are used. This is in every way an advantage, but it does not follow that my plants which require support should be altogether untrained. A good deal of training may be done during growth with the finger and thumb in pinching leading shoots to form natural bushes of such things as will readily yield to that treatment. The best way of training a Fuchsia is to have one central stake, and pinch during growth so as to obtain a pyramidal outline. A few stakes must be used for Pelargoniums; but what few are used should be placed in the plants in good time, so that foliage may have pretty well hidden the sticks before the plants come into bloom. The best hauls at training use the fewest sticks. The best stakes are the very thin Bamboo canes. We have had them about as thick as a lead pencil, and they last well for years. When wood sticks are used, unless the bottoms are charred or dipped in Stockholm tar, they soon decay. There is a great saving in using the Bamboos, and now, when labour of all kinds is getting scarce, one must study economy in the materials used. In cool conservatories fires may now be dispensed with, but where Orchids or other warm-house plants are introduced, fires at night will be necessary for a little time longer. Flowers will keep longer in a cool atmosphere than in a very high temperature, though, of course, nothing under 50 degs. could be called in this house a high temperature. On many nights during March the thermometers in our cool-houses have been very little below 50 degs. without fire heat. Of course, one has to study the outside thermometer and be prepared for a frost at short notice; but the plants are all the better for less fire up to a certain point. There is no doubt that a good deal of fuel is burnt wastefully in amateurs' houses.

Stake.—Repot my fine-folaged plants, such as Anthurium, Abensius, Caladium, Cissampelos, Dracenas, Pandanus Veitchi, etc.,

which may require more pot room. Most of the above require overhauling every spring. Young plants may require shifting into larger pots. Older ones will require fresh compost of a fibrous, porous character. When the stuff gets close and sour, a good deal of the old soil should be shaken away without injuring the roots, and the plant be placed in a smaller pot. After potting, be careful with the water pot till the roots become active. When Allumudas begin to grow freely train the young shoots up near the glass to get the wood ripened and the flower buds set, the shoots can then be taken down and tied round the trainer. If the plants are intended for exhibition, the flowering heads are usually brought round to a face, or at least the best flowers are so treated, though the other side should not be altogether denuded of blossoms. Bougainvillea glabra, Stephanotis floribunda, and Clerodendron Balfourii are useful, easily-grown exhibition stove plants. Madinilla magnifica, when well done, also makes a good specimen that carries weight in a collection, but it requires good culture and a good stove to do it well. Rondeletia speciosa major is a pretty stove shrub, an old thing, but none the worse for that.

Orchard-house.—Trees in pots will require more water now, and the syringe should be used daily as soon as the fruits are set. If the syringe and clear soft water do not suffice to keep out insects, vapourise with nicotine some calm evening, shutting up the house close for the purpose. It is necessary to keep the young growth thin enough to permit of a free circulation of air. It is often desirable, when the crop is fairly set and swelling, to shorten back a branch here and there, if by so doing the shape of the tree and the condition of the branches can be improved thereby. It is an advantage to give the trees a look after the fruits are set, with this object in view. Plums do very well in pots, and Plums grown under glass are superior to anything grown outside. Apricots are not so well adapted for pot culture as Peaches and Plums.

Early Peach-house.—See that the inside borders are moist. Liquid manure may be given freely when the fruits are swelling. Heavily laden trees will utilise a good deal of nourishment. I have used various forms of artificials. At this season something that will act promptly is best. The heaviness or otherwise of the crop is mainly a question of feeding. But to produce year after year first-class fruit, it is best to be content with a modest crop. A healthy, well-supported Peach-tree planted in a well-made border will carry two fruits to the square foot, or eighteen to the square yard. This is not nearly so heavy a crop as market growers generally take, though heavier than was considered desirable years ago in private gardens. Give plenty of space for the young wood to be properly laid in. The fruits should all appear on the upper side of the trellis now as soon as stoning is finished. The night temperature may be raised to 65 degs. to hasten the ripening.

Window gardening.—Those who have no permanent glass may easily improvise boxes that will do for striking cuttings or raising seedlings by laying on empty box or boxes and getting squares of glass that will cover them. The box may be of any size, but 18 inches long by 9 inches wide is a useful size, and 6 inches deep will take 5-inch pots. The glass may simply be laid on the box, and the box stood in the sunshine in the window, but when the sun gets very hot a sheet of paper should be laid over the glass if the cuttings are distressed by the sunshine. Ventilate the frame for half-an-hour every morning, and reverse the glass to prevent damping. A good general compost for repotting anything, except Heath and Azaleas, may be made by mixing 1 bushel of loam with half a bushel of very old manure, and a quarter of a peck of sand. It is a good plan to use sand rather freely to keep the compost open and sweet.

Outdoor garden.—Evergreens may be pruned now. Most things, such as Hollies, Arbor-vitæ, Yews, Evergreen Oaks, and Lawson's Cypress, may want a little help with the knife to keep them in condition. If cutting is done, be careful not to hold some of the branches and the outline is damaged. The

general planting season is drawing to a close for the time being. We have done planting up to the end of April, and in isolated cases have done it later, but late planting involves more labour and attention afterwards, especially as regards damping foliage and branches in dry weather. This is the best season for transplanting hardy Ferns, and rock plants may be moved with safety now. Seeds of summer climbing annuals may be sown now in heat. The most useful of these are *Cobaea scandens*, *Lophospermum scandens*, and *Thunbergia alata*. The last-named should have a sheltered sunny position and be syringed during growth to keep down red-spider. *Maurandya Barclayana* is rather a pretty climber. Finish Rose pruning and sow hardy annuals. Plant all kinds of hardy plants. The *Delphiniums* are very effective hardy plants. Plant *Holly-hocks* now to fill in background.

Fruit garden.—Look over Peaches on walls. Green or black-fly often attacks the young shoots before the blossoms fall, and, if neglected for only a short time, a lodgment is effected which becomes more difficult to deal with later. The best remedy is Tobacco-powder, and it may be used without injury to leaf or blossoms. The only necessity is to act promptly. Melons may be planted now in frames on manure beds substantially and carefully made. Cucumbers also may be planted under similar conditions. We never shade Melons, preferring to give more air to harden the foliage. It is important that the old main leaves should remain on Melons till the fruit ripens. With Cucumbers the presence of the old main leaves is not so important. Strawberries coming forward in cool-houses will get ventilation enough now to set the fruit without help from the brush. The blossoms may be thinned by cutting away all the small ones as soon as they can be distinguished. A dozen large fruits would be a heavy crop for a plant in a pot. There are various ways of feeding Strawberries without deluging the plants with strong liquid, plunging the pots in others one size larger, with rich compost in the bottom, has been used with advantage. Grape thinning should be done before the berries get very large. As soon as it can be seen which berries are taking the lead, thin at once.

Vegetable garden.—Seakale coming forward outside should be covered in ridges a foot or so deep with ashes or burnt earth for preference. Cuttings of Seakale roots, which were taken off in autumn and laid in damp sand or earth, will now be in suitable condition for planting to form forcing roots for next year. Asparagus seeds may also be sown to raise young plants, if not already in. There is not much gained by very early sowing unless the soil is naturally warm, as seeds will not germinate till the sun has warmed the soil. Where only a bed or so is made annually, if there is room under glass to raise the plants, time will be gained by sowing the seeds singly in 3-inch pots and giving them a little heat, afterwards hardening off and planting out in May. Two or three hundred small pots would not take up much room. Sow ridge Cucumbers and Vegetable Marrows for planting under hand-lights. Sow again in a fortnight's time to come on later. Tomatoes should be grown without check from the first, and kept sturdy by exposure to light near the glass. They are better without much heat for planting outside. Nitrate of soda will be useful on Asparagus-beds. French Beans may be sown in a warm position at the foot of a south wall or front of a forcing-house, where protection can be given.

E. HUBDAY.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

April 7th. Finished pruning Tea Roses, and lightly forked over the surface, hurying the mulch. When the hot weather comes a further mulch of loam and old manure will be given to the Teas. We are planting Tomatoes in cool-houses. There is not much in Tomatoes now, but the houses must be filled with something. A range of span-roofed houses has been planted with early Nectarines, chiefly Early Rivers and Cardinal. Potted off *Petunias*, *Heliotropes*, *Ageratum*, etc. by

April 8th.—Pricked off Stocks, Asters, Zinnias, and other tender annuals into boxes and placed in cold-pits, kept close for a time. Planted a house with Cucumbers, chiefly Improved Telegraph. Looked over Vines under glass to stop sub-laterals. The simplest way of managing the sub-laterals is to rub off all below the bunches and stop all above to one leaf; this strengthens the base leaves and buds. Sowed French Breakfast Radishes. Sowed Ne Plus Ultra Peas and Green Windsor Beans.

April 9th.—Planted out a lot of hardy bulbs from the conservatory which have flowered. Shifted on a lot of *Clivias* and *Achimenes*. We had potted tops of *Achimenes* make useful table plants in 5-inch pots. Half a dozen cuttings are shifted when rooted into 3-inch pots, and are encouraged to grow freely in heat. Planted out more *Calliflowers*. Sowed seeds of *Dietonnis Fraxinella* in boxes. Prepared a small hot-bed for striking cuttings of Tree-Carnations. Divided white Everlasting Peas to increase stock.

April 10th.—Moved plants to cold-pits to make room in houses. Shifted on *Zonal Geraniums*. Sowed seeds of *Arabis Sieboldii* and *Grevillea robusta*. Repotted and basketed a few Orchids which are showing signs of growth. We have just fixed up the roller blind on the stove, but it is only used when absolutely necessary. Potted off Begonia cuttings. Shifted on young Ferns. Palms and Ferns are shaded during the heat of the day.

April 11th.—Rearranged conservatory to form special features of *Spiraea* and Ferns, mixed *Periploca*, *Azaleas*, *Erica Cavendishi* and *E. propinqua*. Good-sized clumps of *Diclytra* and Trumpet *Lilium* are elevated. Bamboos and Palms, chiefly *Kantias*, are used as centres and backgrounds. Made new plantation of Mint. This is easily done by severing the young stems underground with a knife. They then fit with roots, and are planted 6 inches apart.

April 12th.—Finished planting Potatoes. Tied up Lettuces. Young Cabbages are plentiful now on warm border, and new Potatoes in frames. Sowed Ne Plus Ultra French Beans on border in front of forcing-house. Sowed more Winter Greens of various kinds, also Leeks for late planting. Early Leeks were sown in a box and are ready to transplant. Spare time (if any) is devoted to surface stirring.

LAW AND CUSTOM.

Repudiation of verbal hiring of house (Perplexed).—You say that a verbal offer of the premises was made to your friend, and you imply that he verbally accepted the offer. He, however, has not received possession, and, in fact, the tenancy of the present occupiers has not yet expired. As your friend has reason to think those occupiers will not quit upon the expiration of their term, he has taken another house and repudiates this verbal hiring. In my opinion, I do not think any damages can be recovered from him—certainly not any rent—as the contract was not in writing.—K. C. T.

Nuisance from chimneys. During the last three years burning ashes from chimneys have been constantly deposited in my garden, destroying all my vegetables and trees. When I complain, I am insulted by the manager of the firm, although I have lived here thirty years. What is best to do?—R. J. J. J.

[You do not say how far away these chimneys are, nor with what work they are connected, nor how long they have been in existence. Apparently, the nuisance commenced three years ago, and, if so, you have a remedy by action for damages. But as the statement of facts is so vague, I must recommend you to consult a solicitor.—K. C. T.]

Carriage license.—I have bought a new spring cart. Shall I be obliged to take out a license for it? Must I have the nature of my business—marked gardening—set out along with my name on the cart? I do not wish to have the words "market garden" placed upon the cart if it will suffice to set out my name and the place of my residence.—MARKET GARDENER.

[If your cart is constructed and adapted for the conveyance of goods or burden in the course of trade or husbandry, and is used only for such purposes, you need not take out a license for it; but your name and place of abode must be legibly painted on the cart in letters of not less than 1 inch in length. The nature of your business need not be set out on the cart. If the cart is used for other purposes you must take out a license for it.—K. C. T.]

Assessment of greenhouses.—I hold a small farm as a market gardener. Date of entry, 1900. On taking possession I built five greenhouses, 75 feet by 12 feet, for Tomato growing. The overseers now want to assess me. The district is under a Rural District Council. Can they do so under the circumstances?—J. D.

[The greenhouses may be, and properly speaking, should be, separately assessed for the purposes of the poor-rate, and charged to the poor-rate at the full pound-rate payable in respect of buildings and other hereditaments which are not agricultural land. If any separate rate is made by the overseers to defray the special expenses of the rural council, the greenhouses should be rated to that separate rate at one-fourth of the rate in the pound charged upon houses.—K. C. T.]

Terms of tenancy. I think of taking a cottage and garden on a lease for three or five years. Is it usual to pay rent yearly and in advance, and for each party to hold a copy of the agreement? Would the lease be determined in the event of my death? If so, what notice would my wife be entitled to or expected to give? I should be grateful for advice on these matters.—CONSTANT READER (A. S.)

[It is not usual to pay rent yearly, nor yet to pay rent in advance, but both practices are often seen. Rent, where the premises are let for a term of years or by the year, is sometimes payable yearly at the end of each year; and occasionally, although very rarely, is payable yearly in advance. It is commonly payable half yearly or quarterly, sometimes in advance, and it is not uncommon to stipulate that the rent for the last half year (or the last quarter) of the tenancy shall be payable in advance. The agreement of tenancy should be in the custody of the tenant, but a copy signed by the landlord should be in the hands of the landlord. If the letting be for a period of more than three years, it must be in writing under seal, unless the landlord and yourself enter into an agreement for a lease, when sealing is not necessary. Unless there was an express stipulation to that effect in the agreement, the tenancy would not determine upon your death, but would devolve upon your executor or administrator, who would be entitled to receive the same notice, and would be required to give the same notice to determine the tenancy as you will have to give or receive if you survive. It may be well to point out that, where the letting is for a term of years only, and no provision is expressly made for a yearly or other tenancy upon the expiration of the term, no notice is necessary, and the tenancy ends without any notice from either party. All the matters about which you inquire are matters for mutual arrangement beforehand, and should be dealt with in the lease or agreement of tenancy.—K. C. T.]

POULTRY.

Death of hen (J. Brown).—This bird was excessively fat, and appears to have died in a fit of apoplexy. The crop was very full of corn. Obesity, or excessive fatness, is really a disease caused, as a rule, by partaking of food of too rich and stimulating a nature. Most poultry ailments are brought about by over-feeding or the use of unsuitable food, and the free use of Maize is sure to lead to the foundation of internal fat, and as this accumulates egg production ceases, and the hen falls a victim to disease. It would be well, in your case, to discontinue the Maize, and let the diet of all your Fowls be of the plainest, and restricted in quantity, at least, for a time, otherwise you will, in all probability, find many of your hens drop off in the same way. As liver disease is often caused by high feeding, it is very possible some of your hens may be found to be suffering from this complaint, the symptoms of which are a moping about on the part of the bird, an irregular appetite, while there is generally a yellowish hue on the comb, face, and wattles. If these symptoms are observed the best treatment is to give one grain of calomel per bird every other day for a week or so, mixed in the soft food, which should be given in a crumbly state. Give plenty of fresh vegetables, and having lessened the quantity of grain for a time (to allow the digestive organs to recoup their strength), add some sulphate of iron to the drinking water after the course of medicine has been gone through. The most profitable and satisfactory mode of general feeding is to give no more at a time than can be eaten readily and hungrily, and to frequently change the diet.—S. S. G.

CDRESPNDNDE.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow these rules: All communications should be clearly and concisely written on one side of the paper, and addressed to the Editor of GARDENING, 15, Finsbury Avenue, Holborn, London, E.C.

Naming fruit.—Readers who desire our help in naming fruit should bear in mind that several specimens in different stages of development, and also of the same kind grown in different soils, are essential. We have received from several correspondents single specimens of fruit or leaves, these in many cases being mixed and otherwise poor.

PLANTS AND FLOWERS.

Chrysanthemum Chas. Davis (H. C.).—This is a very early plant to grow, and any buds retained during the latter part of August will give flowers of excellent form and colour.

Roses shedding their foliage (An Old Subscriber).—The manner in which the leaves seem to be the cause of your plants shedding their foliage. Sometimes the leaves will do this when they are introduced into strong heat before they are established in their pots.

Cannas falling (Swindon).—It was a mistake to turn the soil so dry when you potted them. Very probably the soil even now is not moistened throughout. You may have been watering too freely, making the soil sour, and thus preventing the formation of roots.

Chrysanthemum for decorative uses (Widley).—Your plants represent four types, and, assuming you desire them to bloom from late October onwards, you should stop or pinch them three or four times during the growing season.

Renovating lawn (The Cedars).—If the Grass on your bare patches of lawn be quite dead, your best course will be to turn it over a few inches deep, make the surface fine and level, then sow properly sown Grass seeds, not from a seed-bank, but not too thickly, lest the density starves the whole of the Grass.

Rose-buds injured by insects (Calypso).—Probably in your country you have insects which prey on roses that are not known to us here. It is said there are over 100 species of insects that are injurious to roses. We should say that they have been at work, either the Rose-chalicer or one of the many species of fly that lay its white eggs beneath the bushes at night, and give a vigorous shake, you will probably obliterate some of the insects.

Pyrethrum Jubilee (A. R.).—This is regarded with great favour by all who have seen it when in blossom. The flowers are not so large as in many of those which are not in introduction, but they are quite large enough, and their form is all that could be desired.

Pruning Niphetos under glass (Canton).—You are quite right. These fine old plants need severe pruning now and then in order to encourage the production of new wood. You must wait until the blossom has faded, then you may cut back the plant.

Planting Ranunculus (Surrey).—It is one of the more favoured parts of these islands that the roots of

claws, as they are termed, can with safety be left in the soil all the year round. Where the soil is well drained, light, and warm, this may be done. In all others it is necessary to lift them each year in the month of July, and dry them thoroughly before re-planting them in October or November.

Treatment of Aloe (Lew).—The genus Aloe belongs to the order Liliaceae. Nearly all of them are natives of North Africa, and while some are low-growing, others attain quite a tree-like dimensions. They all need the protection of a greenhouse, but exposure to the sun throughout the year, a moderate amount of water when watering, but scarcely any during the winter, and for potting soil use two parts loam to one part of leaf-mould, and the same amount of rocks, or, better still, soft bricks broken about the size of horse beans, with half a part of sand.

Newly-sown lawn (J. G.).—You certainly sowed Grass and Clover seed on your lawn very early, as the usual time for so doing is in April. However, if we get no sharp frosts next month, the Grass will soon grow, and, being treated by the recent rains, should grow strong and dense. If you can, a week or two hence, give the lawn a heavy dressing of soot to wash in, it will do much good.

Mulching annuals (D. D.).—If you have treasured your border in which roses and herbaceous plants are now growing 3 feet deep, and well manured, it, such a position should not appreciably suffer from drought. Still, if the soil gets very dry in hot weather, you cannot do better than cover the surface all about the plants and roses with at least 2 inches thickness of manure, and especially, if you have it, run-manure, as that is best. If you dislike to see the manure, cast over it the lower part of your plants, leaving them objectionable, though soon drying up. If you can afford to water during dry weather, the manure elements will be washed in and do good.

Sweet Peas—planting out the earliest batch of plants (Tom).—Seeing that you commenced operations under glass so early as January last, and have been growing your plants steadily since, and assuming they are now nicely hardened out in the open air, you need not hesitate to commence planting into their flowering quarters as opportunity offers. Begin by planting in the warmer quarter of the garden first, as we are sure to have many unpleasant days of frosts besides experiencing cold and cutting winds, within the next week or two.

Marchal Niel and Homer in greenhouse (Poodle).—We presume these two roses, when planted in the large pots you refer to, had not previously been grown in pots, but were dug up from the open. It is such was the case, and they were given 60 days of heat at home, this may in some respects be the cause of the plants dying. But are you sure they are dead? Sometimes such plants will shed their foliage prematurely and yet not die.

Rose White Marchal Niel in cold greenhouse (E. H. Simpson).—The foliage received was covered with the excreta of the green-fly. The sticky substance of the foliage causes it to collect particles of dust floating in the air, which, unless dislodged off, will seriously injure a growing plant by blocking the pores of the leaf.

house secure against the too rapid escape of the smoke. A good syringing following the fumigating and on every occasion when sun is bright would soon cleanse your plants from dirt as well as aphid.

Tall-growing plants (Canton).—You ask for tall-growing scarlet or yellow-flowering plants for August and September. You would, however, to say whether tender plants or early perennials are desired. Of the former there is, perhaps, nothing more suitable than Cistus Dahlias, such, for instance, as Glare of the garden and many more possessing the same vital colour or approaching thereto. Of the hardy plants the Kniphofia come nearest in point of colour, and particularly such as 'L'aria, nobilis, grandis, all of these having tall spikes of orange-scarlet flowers and lasting a long time in profusion.

Plants to flower in spare room (R. J. H.).—If you have no other means of giving the plants their room in question, we fear you have little chance of success. It is one thing to flower many bulbous plants in such a place, but the flowers, already existing in embryo within the bulb, are prevented as the natural course of growth; but it is another matter when the plants are of the soft-wooded class and produce their flowers on the current wood or growth. You may, however, utilize all the light the windows will give you, and in this way grow and flower such plants as Zonal Pelargonium (Zonalans) in variety, Fuchsia, Campanula fragilis, C. isophylla, several of the Cistus family, Valeria pinnatifida, Galadivus in several sections and their varieties, Arum Lily, Saxifraga saxatilis, Tuberosa Begonia, that alone in our list afford a splendid variety of colour, and may now be purchased at very trifling and bettered at once. Another good thing is Hydrangea Hortensia, and all the more available because hardy and capable of standing outside in winter. Eucalyptus heterocera fol. var. and the Indian Montserrat would afford a couple of good trailing plants, apart from the Campanulas named above, that are well suited to the same purpose. To these may be added a few pots of Mignone, best grown on the window sill, and some pots of the further, both being easily grown from seed. These should at least afford you variety, and it is easy enough to purchase a plant now and again. You will need to exercise some care in the watering and general attention day by day.

Hyacinths falling (Aurora).—At the present month, two things per thousand bulbs would be of no probability for the second or third rate quality, from which it would be impossible to obtain first-class flowers, however grown. Still, from the description, we should say that yours have had insufficient light, and very possibly an excess of water at the roots, for though Hyacinth need to have the soil kept fairly moist—that is, when the roots are quite active, yet if kept too wet this causes an undue development of the foliage, often at the expense of the flowers. We should advise you next season to obtain better class bulbs, potting them in a good, open compost, such as a mixture of turfy soil and three parts of peat, and dung. Then stand them outside, give a good watering through a moderately fine rose to settle the soil thoroughly in its place, and cover with asters or Cocca-nut-ruff. This covering will tend to keep the soil in an even state of moisture and encourage the formation of roots, upon the ample production of which so much of the success or otherwise in the culture of the Hyacinth depends. Then, when the pots are filled with roots and the tops commence to push (which will be six weeks for the bulbs from the time of potting), the soil is raised about 2 to 3 inches, and a very reliable plan for them, in mixing the compost, some good rough sand is very essential to keep the soil open, and when the plants are placed in the window, if saucers are used to stand them in take care that no water is allowed to remain in the saucer, as this will cause the roots to decay, and failure result therefrom.

TREES AND SHRUBS.

Planting out Jasmine (H. S. Sweeney).—The Jasmine will succeed in any good garden soil. Planting may be carried out in the autumn, winter, or early spring months, before growth recommences—that is to say, when it is intended to remove a planted-out specimen from one spot to another. Should, however, the specimen be in a pot, it may be planted at any season, and in most nurseries Jasmines are kept in pots for that reason.

Gum-trees (Eucalypti) (A. W.). You will find that none of the Eucalypti are hardy unless in mild seashore gardens, and even then they are liable to be killed. Only in the more favoured districts take the Gum-trees any chance, and they never present the graceful and stately appearance which they show in countries which suit them. The common E. globulus is used in the London parks during the summer, but the trees will not stand the winter. If you wish to try any of them, you should write to T. Smith, Newry.

Pruning Prunus triloba (H. S. Sweeney).—If it is necessary to prune Prunus triloba at all, this should be done directly the flowering season is past, as it is the young wood produced after that period on which we have to depend for flowers the following season. This applies only to plants that are pruned hard, as unless special reasons exist for keeping the plant within its present bounds the greatest wealth of blossoms will be obtained if the pruning is strictly limited to the removal of any weak, old, or exhausted shoots. This may be carried out as soon as the flowers are over.

Planting out Rhododendron (S. C.).—There are so many kinds of Rhododendron that without knowing the name of yours it is difficult to advise. It is one of the hardy varieties that may be planted out of doors as soon as the spring frosts are over. In planting see that it is planted deep, and at such a depth that there is a saucer-shaped depression in the soil around the stem, in order to

FRUIT.

THINNING APPLE BLOSSOM.

(Reply to "E. G.")

In the case of newly-planted, or even trees established three or four years, it is a decided advantage to thin the bloom buds where the trees are heavily laden. It is not always those trees that have a superabundance of blossoms that carry the heaviest crop of fruit. Take for instance a three-year planted bush tree of any of the large fruiting kinds, such as Warner's King or Pausgood's Nonsuch; in view of the regard to the quality of the Apples would think of allowing the trees to carry more than two dozen fruits, and this would be an exceptionally heavy crop for these large kinds. Trees of this size will most likely have at the present time ten times that number of bloom buds. My plan is to thin these before they develop. I find then I have many small fruit to take off in thinning the crop. The thinning of Apple blossoms may appear a trivial and a laborious waste of time, not justified by results, but it is surprising what a quantity of bloom buds can be rubbed off in an hour by simply giving each a sharp press with the forefinger in a downward direction. In thinning the buds I take off whole clusters in many cases, especially those situated under the branches, and those in a high position where the fruit would obtain but little sunlight, and consequently would be of poor colour. I aim at having the best placed fruit, and by removing some of the central buds in many clusters, retaining some of those less forward, I get two strings in my law in the matter of securing a crop of fruit, as seldom are all the blossoms on the tree open at one time, and by making certain of having the blooms expanded at various times the flowers are more likely to escape wholesale destruction by one visitation of frost. I find that trees are not nearly so liable to drop their fruit wholesale in the incipient stage of swelling when thinning the bloom has been practised. In the case of trees planted last autumn, I always remove all buds the first season, except in extreme cases of wishing to prove any particular variety, and then I only leave sufficient for the purpose. Newly-planted trees ought to be encouraged to make free growth the first year. Where trees are allowed to carry a full crop of fruit—varieties like Lord Grosvenor, Lane's Peuce Albert, and Stirling Castle will do, the growth is so weakened that it is visible in many instances for years after.

In the matter of standard-trained trees especially, I never allow them to fruit the first year. I remove all the flower-buds directly they are large enough to handle; the whole energy of the tree is thus concentrated into the growth of the branches and roots. The larger a tree becomes in the shortest possible space of time, the greater prospects are there of obtaining a full crop of fruit in years to come. I know there are many owners of trees who think they have made a poor bargain if the trees just planted do not give them a fair return the first season, but such persons do not remember the best

reward after a series of years. Trees in their weakened state, occasioned by the check given to the roots in replanting, cannot be expected to reasonably give adequate returns both in wood and fruit; one must suffer, and it is much better for the future prospect of the tree that the fruit crop should suffer. E.

PRUNING FILIBERTS.

In many gardens both Culi Nuts and Filiberts are very much neglected, seldom getting properly pruned, manured, or otherwise attended to. This may arise from a variety of causes, such as living in out-of-the-way situations, and therefore possibly forgotten in the press of work that must be done in the houses and kitchen garden, March and April being always a busy time, and which is the right season for pruning the trees. Experienced Nut growers never prune until after the flowering period, their contention being that it is desirable to have as many catkins as possible, so that plenty of pollen may be obtained to set the female flowers. That their theory is correct must be clear to all, for if the pruning were done early many of the male blossoms would of necessity be cut away, and there would be a danger of an insufficiency of pollen to secure a good set or crop.

In pruning Nuts, the centre of the bushes or trees should be cut out, leaving the main outside branches to grow on uncheckered for two or three years, and then heading them outwards and securing them to stakes, which gives a large and prolific bush in a few years from time of planting. The plan of bringing down the main branches in the manner described appears to me as a check on any grossness of habit, and induces the formation of plenty of small wood adapted to produce heavy crops of Nuts. No greater mistake in Nut culture could be made than to cut away the major portion of the fine, twiggy wood, leaving all the strong shoots, as it is the thin wood that really bears the crop, but if late summer pruning is done no strong shoots will be present in spring, as they will be either entirely removed or shortened back, according to the judgment of the grower. At the same time, while plenty of thin wood is desirable, care should be taken that it does not become too congested or too thick in the middle of the tree, thereby impeding light and air, and also inviting a harbour for insect foes. All suckers ought to be removed as they appear, unless required for increasing the stock; when allowed to grow they act as robbers to the trees, and do more or less injury to them. Immediately it is seen that a good crop of Nuts is assured, a mulch of good manure will be beneficial, causing the foliage and fruit to attain a large and healthy size, and assisting the trees to form bloom-buds for another year. No trees pay better for liberal treatment than Nuts, and yet few if any trees receive so little aid in that respect in many places. Even the common Hazel appreciates a dressing of manure, being almost unrecognisable after such an application. The Nuts acquiring a much improved appearance, also being produced in very large clusters.

NOTES AND REPLIES.

Muscat Vine not bearing.—That a black Hamburgh and a Muscat Vine in a greenhouse, the Muscat in the southern end of the house, both in outside borders, which were much enlarged and fresh drainage and soil given last winter to allow space for the surface roots, of which there was plenty. Now the black Grapes are ever promising, but the Muscat Vine, though apparently perfectly healthy and vigorous, has very little show of fruit, only a few little bunches. It is probably an old Vine, as it has been cut back some time, but my knowledge of it only dates from November, 1900, last year it was a failure. Will you tell me what is best to do with it? My lease may terminate in 1907.—H. M. T.

[This Grape never succeeds in a cold greenhouse, as it requires a warmer temperature and a drier atmosphere than most other Vines to set the fruit properly. Thus special care is required in setting, and a higher temperature must be given when the fruit is ripening. For all Muscat Grapes the borders are better if entirely inside. We should advise you to take up some pots from the B. Hamburgh to take the place of those belonging to the Muscat, which will never succeed with you, being, as it is, at the coldest end of the house.]

Mealy-bug on Vines.—Enclosed are two parasites from Vines. Are these Vines mealy-bug? Occasionally find one or two on the Vines, which are now in blossom, and use M. M. one to eight of water, with a small brush, which seems to kill them. Must I strip the Vines and wash them next winter?—F. POWELL, VINE.

[Unfortunately, the pest you send samples of is mealy-bug. In dealing with it when the Vines are at rest, avoid any emulsion containing petroleum. Methylated spirit is much safer and more destructive. Many gardeners use with great success a mixture of gas tar and clay for painting Vines attacked by mealy-bug, first clearing off the loose bark to facilitate the work of painting. The tar-paint is made by first mixing up the clay with water until it has the consistency of thin paint. Add the tar, about a pint to 1 gallon of the clay and water mixture, and keep well stirred. This is certainly not a pleasant paint to use, but it is very effective. It must not be forgotten that the house itself—walls, stages (if any), wire-trellis, and roof—must also be thoroughly cleaned. Nothing is better than painting all wood and iron-work. If this cannot be done with red-paint, then use petroleum, being careful that none touches the Vines. Point over the surface of the border if an inside one, and wear it off and burn it. A sharp watch must be kept on the growing Vines in the summer, as many stray insects appear. Methylated spirit applied with a feather is useful for the summer attack. Mealy-bug is such a troublesome insect that any means of getting rid of it, no matter at what trouble, is well repaid. Perseverance is the great factor.]

Planting out Strawberries in autumn.—Spring planting is to be recommended in some instances. This applies to small, late-rooted runners. When the season is very dry it is difficult to get runners of some kinds early, and frequently when runners are ordered from nurserymen in such seasons they are very small and arrive late in autumn, and sometimes it happens the ground cannot be cleared in time to plant early in autumn. I have had all these difficulties to contend with, and now, unless I can plant good strong

runners by the end of August, or early in September from pots, I prefer to plant them in spring. Years ago I used to pot these late runners into small pots for the winter. This caused much labour; but of late I have adopted the system of planting them in beds, some 4 inches or 5 inches apart, in a favourable position, keeping them moist when first planted, and allowing them to remain here during the winter. In this way they make nice plants, and can be lifted with a ball of soil to them. If the soil is in good condition they start into growth rapidly in spring, and there are no gaps in the rows, which frequently occurs when planted in autumn from frost lifting them out of the ground. I plant Lettuces or Onions between the rows of these spring-planted Strawberries with the best results.—J. Crook.

PLANTS AND FLOWERS.

ROOM AND WINDOW.

MARGUERITE CARNATIONS.

THESE Carnations have now been in cultivation some few years, but they are not at the

necessary to aid in maturing the growth. The seed should have been sown early in March, but it is not yet too late to do so. Do not, however, endeavour to make up for lost time by raising and growing the young plants in too much warmth. By the time the seedlings are pricked off a cold-pit or house will afford sufficient protection for them. Although there is in some instances a perceptible fragrance, this much appreciated merit of the Carnation is not a strong one in this strain. Where it is not convenient or practicable to grow a stock of the other Carnations in pots, there the Marguerite Carnation will be the most useful. As in the case of all seedlings, there will be a percentage of singles which should at once be destroyed. P.

WHITE FLOWERS FOR ALL SEASONS.

WHITE flowers are acceptable at any time of the year, and trade growers devote much room, both indoors and out, exclusively to their production. Many private growers fail to have the proportion of white blossoms in their gardens and glass-houses they might have, and it has occurred to me to consider those that will meet one's requirements throughout the

Lady Hall, Mrs. James Hall, and Progress. Later varieties give us a wider range, and I would draw from such sorts as Aphrodite, Mrs. Keynes, Lucy Genin, Niphotos, Venus, James Markay, and Mrs. E. H. Jenkins. Paeonies are bold and effective, and are now too well known to need commending. Snopdragons are of much use in a garden and about rock beds, etc., and both tall and dwarf varieties contain some of the purest white kinds. Irises should be grown by all who make a speciality of flowers for cutting, and those mentioned are suitable for this purpose: Alba, Ilorentina, and abbeas Princess of Wales. Varieties in which for the most part white predominates are: Victoria, Mme. Chereau, Mrs. H. Darwin, Herald, and Gazelle; Iris hispanica Blanchard, Antonia Johanna; Iris Kämpferi Snowbound, Snow White, Mrs. C. Saxton, Eclair. Lilies have always been popular for indoor cultivation; but, notwithstanding all that has been written with regard to them, there are still many who have a deal of misgiving as to the suitability of some varieties for outdoor growing. With few exceptions, Lilies may be grown in the open air; indeed, often better than under glass. White varieties that are thus fitted are: Giganteum, cordifolium, ramulatum, longiflorum Harrisii (one of the best for early forcing), insulare (a charming Lily, but needing to be better known), Martagon album, and speciosum album Kratzeri. A word must be said in favour of climbers bearing white blossoms. Reverting to

Marguerite Carnations in a Jar.

CLEMATISES, we have Flamula (sweet scented), Smith's Snow White, Andersen Henry, Imperatrice Eugenie, Mme. Van Houtte, Lucy Lemoine, and Duchess of Edinburgh. Jasminum officinale, Starworts, Chrysanthemums (early-flowering), and Christmas Roses are also useful. Among plants indoors we have the beautiful Clematis indivisa lobata, Plumbago capensis alba, Stephanotis, Solanum jasminoides, Cinerarias, Primulas, Azaleas, Zonal Pelargoniums, Cyclamens, Camellias, Begonias, Hyacinths, Tulips, Lily of the Valley, Snowdrops, Spireas, Chrysanthemums, and Peutzias.

ROSES provide us with numerous choice sorts. From them we select those that may fairly be termed white. Teas: White Manum Cochet, Souvenir de S. A. Prince, Marie Guillott, Mme. Bravy, Hon. Edith Gifford. Hybrid Teas: L'Innocence, Bessie Brown.

CLIMBERS: Souv. de la Malmaison, Niphotos, Devoniansis, and Aimee Vibert. Hybrid Perpetuals: Marchioness of Londonderry, Boule de Neige, and White Baroness.

LEAFYEST.

GLOXINIAS provide us with a superb display of colour, and the treatment to ensure a magnificent display of flowers is practically the same as that needed for Achimenes. Gloxinias may be bloomed the same season from seed, provided a start is made in January or February, and those who prefer raising their own plants to the less troublesome but more expensive mode of starting with tubers should obtain their seed from a good source, sowing it very thinly in well-drained pans, in loam, sand, peat, or, failing this, leaf-mould, in a good bottom-heat, watering with a fine rose, and keeping the surface moist until the young plants are up and ready for removal. By pricking them off into small pots and finally shifting them into blooming pots one may have flowers in July and August.—W. F.

Greenhouse climbers (Enquiries) — *Lonicera sempervirens* minor, *Plumbago capensis*, *P. c. alba*, *Heliotropium*, *Tropaeolum* (Ball of Fire, Rose Gloire de Dijon, and Colosa and many others), all these blooming greenhouse climbers have flowers that, first, having a violet flowers, is the best.

present time gaining in favour. For this there must be some cause, not necessarily the same in each particular instance, but none the less so. Being raised, as a rule, from seed rather than from cuttings, there is a predisposition to make a luxuriant growth, not altogether robust perhaps, but of rapid development and consequently sappy. This should be guarded against by not using too rich a compost from the very commencement. Under pot culture it will be better to employ chiefly loam and sand, with a little leaf-soil if the former be not all of a heavy character. It will be better, also, to err on the side of small pots rather than the opposite extreme. Some of the best flowers I have seen were from plants in quite small pots. Firm potting will also tend to better results, whilst no artificial feeding should be allowed until the plants are well advanced in the flowering stage. Another mode of culture is that of planting the seedlings out, but the same lines as regards soil and its firmness must be observed. If planted out the growth will be greater, whilst a more bushy habit will result. So far there is an advantage, but sufficient time must be allowed for fresh root action when lifted before cold weather again sets in, otherwise the plants will not be good. In any case plenty of light is absolutely

year. At the present moment a number of people are choosing seeds to sow within the next few weeks, and I would like to point out some half-hardy annuals, viz.: Sweet Peas Sadie Burpee and Blanche Burpee, Stocks, Galetia Duchess of Albany, Dianthus, single and double, Centaurea, Candytuft, Asters Caneet and Victoria, Clarkias, Convolvulus, and Verbenas.

CANTERBURY BELLS, and other members of the Campanula family, like *persicifolia grandiflora alba*, *pyramidalis alba*, and *virgatica alba*, afford a plentiful amount of blossoms. One remembers, too, some excellent sorts of Pinks that are of much value on account of their sweetness, such as Her Majesty, Mrs. Sinkins, and Albino. Turning to Carnations, mention may be made of Empress and Gloire de Nancy. Tufted Pansies flower freely and long, and white sorts, of which there are some good examples, come in useful for small bowls and specimen glasses. Niphotos, Mrs. Scott, and Mrs. Kinnaird are instances. Pyrethrums and Phloxes are both showy and popular for a garden, and of the former I select of the doubles: Mont Blanc, Penelope, Carl Voget. Singles are best represented by Princess Marie and Alsica. From Phloxes, of the early-flowering sorts, one cannot do better than select

ROSES.

ROSA RUGOSA MADAME GEORGES BRUANT.

It was a happy idea that led M. Bruant to hybridise Rosa rugosa with the fine old Tea Rose Sombreuil, and thus enable him to introduce to our gardens some fifteen years ago the first hybrid of this very hardy race of Roses.

A glance at the illustration will show in what manner this hybrid partakes of the Tea-scented characteristics, the fine clusters, containing from six to twelve buds and blossoms in each, being quite Tea-like in appearance, and the elongated buds may often be gathered nearly equal in refinement to the Tea Rose Niphetos. Mme. G. Bruant may be classed among the very best of our garden Roses, and the wonderful profusion of blossom gives the plant much value. It is an excellent variety for massing in bold groups, as at Tresserve, not

growths being more erect than in some of the other kinds. Upon standards this variety makes a splendid head of growth, typical of what a standard Rose should be. For planting in public parks or near large cities the Roses can equal the Rugosa forms. There is now a numerous collection of the flowers, ranging from purest white to delicate pink and from deep rose to dark purple. Atropurpurea is a great gain, and is probably the basis of some really good dark and brilliant colours. Hitherto many of the coloured kinds were "washy" and lacking in freshness. Some lovely hybrids of Continental and American origin may be seen in the Rose dell at Kew Gardens in June. One particularly pleasing hybrid between Rosa rugosa and R. Wichuriana had the creeping habit of the latter with the lustrous foliage of the former. Rosa microphylla x R. rugosa had large Clematis-like petals quite 2 inches wide and of a delicate bluish-pink colour, and another splendid hybrid R. rugosa x General

Mme. Berard, and Celine Forestier. It would not be a difficult matter to prepare the border for these Roses, removing half of the light soil, and mixing with remainder some turfy loam, if procurable, and well rotted manure. The soil should be removed to a depth of 2 feet 6 inches, and immediately on to the gravel place a good layer of cow-manure, and fill up with the compost mixed as advised. Being very porous, such a border would require water rather frequently during the summer. Half-standards on pliable stems would be the best to plant, but they could not be procured until next autumn. One reason for recommending half-standards is the fact that their stems would withstand frost better than the growths of the Rose, as you say you are about to plant the Roses outdoors and bring them into the house through holes prepared for them.]

Hardy plants for Rose-beds.—I have in the front of my house, facing the south, two large oval Rose-beds. Behind them against the house runs a narrow

Rose Mme. Georges Bruant at Tresserve. From a photograph by Miss Willmott, Wipley, Essex.

merely for a summer display, but also for late autumn. Last September a bed of this variety on the lawn was very beautiful, some of the current season's growths reaching 5 feet in length, and crowned with grand clusters of snow-white blossoms. The formidable-looking prickles on these new growths are as numerous as those on a hedgehog, and even in winter have a beauty that compels admiration. The individual flower of another lovely kind, Blanc Double de Courbet, is perhaps more attractive than the Rose under notice, and if only one variety could be grown I should not hesitate to recommend it in preference to Mme. G. Bruant, the dark foliage being much superior. This variety also fruits fairly well, whereas we obtain no fruit from Mme. G. Bruant.

For hedges, the Rugosa forms are of great value, not merely ornamental, but useful also, acting as a wind-break. In the above-mentioned relation, the Tea Roses, Mme. Georges Bruant is well adapted for this purpose, its

Jacqueminot was perhaps the most beautiful of all. The fine plant of this hybrid was a dense mass of single crimson blossom, each one with a distinct white eye. Rosa.

NOTES AND REPLIES.

Fragrant Roses amongst Teas (p. 79).—Wind about, Goulanit, Debonensis, Aurora, Besse, Brown, Peter, Viscountess Folkestone, Mme. Caroline Testoil, and Mrs. E. Mowley? There are many climbers very sweet. Mme. Alfred Carriere, Desprez à fleurs jaunes, Mme. Henriette de Beauvain, and Mme. Isaac Perriere.—FRAGRANCE LOVER.

Roses for lean-to house.—I have a lean-to glass-house outside sitting-room facing N. by W., and think of planting Roses or climbers outside, and passing stems through holes in frame. No sun is on the glass except about sunset in midsummer. Will you oblige me by saying what you recommend me to plant? The soil is a light one with gravel subsoil.—N. R. L.

[Two of the best Roses for your purpose would be Cle de Dijon and Cheshunt Hybrid. Should you have space for more than two they either of the following would do—namely, Mme. Alfred Carriere, W. A. Richardson,

1-foot border, in which are planted W. A. Richardson Rose and Jasmines. Both beds and border get very much scorched by the sun in summer, especially as I am lying on a gravel subsoil. Can you suggest any way to avoid the midwinter of the Roses in summer by keeping in the noisome, and semi rock plants and alpine do well in the narrow border? If so, what kinds would be best? I would rather not put on manure during the summer if I can avoid it, as the beds are just under the window. I am much obliged for your recent advice.—HALFCROFT.

[The best remedy would be a general deepening of the soil in the Rose-beds by excavating some of the subsoil, and filling in with soil and good cow-manure buried 18 inches deep. There is nothing like depth of soil and a cool root-run to remedy the evil of which you speak. You cannot engage in this work now, and must be content with the next best thing. If you plant rock or dwarf plants on the surface, to act as a mulch, so to speak, the soil below will be the poorer, though, as retainers of moisture in the best manner. Rose-beds do not know something of the value of such plants as Mossy Saxifragas, Ruffo Red example, S. S. C. p. noïdes, S. Staus-

field, S. Sternbergi, etc. S. Wallacei is also a good one. The great value of these plants is that they can be planted frequently. Any of the Aubrietias are good, and give a carpet of bloom in early spring; and so, too, the white Anthesis. Had the position not been so hot, we should have strongly recommended Tufted Pansies, and these may be best even now if you deepen the soil in the coming autumn. Another beautiful plant for carpeting the surface is *Campanula muralis*. It is dwarf, dense, and free-flowering. If you follow the lines suggested, we think the most useful plants for this year, considering time and other things, will be the Saxifragas named previously, as these may be dibbled in freely by lightly stirring the surface soil.]

Roses in the greenhouse. Kindly tell me in your next issue why my Roses in bud in the greenhouse throw back the petals of their calyx before they open properly? I have *Maréchal Niel*, *Climbing La France*, and *Fortune's Yellow*.—*QCEER*.

[A brief, yet a perfectly correct, reply to your inquiry would be, "That it is their nature so to do." If you look at the embryo bud you will note, provided it is a perfectly formed bud, that not only do the parts of the calyx completely overlap the top of the bud, but that a crown-like tuft overpreads and thereby protects the petals that at such time are just forming. With the latter function completed, the petals rapidly increase in size, and naturally the calyx, which is Nature's protective envelope up to this point in the developing buds, gives way. If this were otherwise nothing short of stragulation would ensue. You will note that not only is there a crown-like tuft of the calyx above the bud, but that the entire segments of the calyx are twisted into a screw-like pattern, and with the bud below really resolve into the same glass pattern, the centre being reduced to a minimum. In these circumstances the developing petals force the segments of the calyx asunder, and with still further development the calyx is divided in its natural parts, and presently expands, sometimes opening only with the petals of the flower and closely adhering thereto, at others flying back either horizontally or even reflexing. Long, tapering buds, as *The Bride*, *Bridesmaid*, etc., retain the calyx close to the reverse of the petals, the same thing happening in greater or less degree in *Roses of the "Verdier" group*—say *Mrs. J. Laing*, *S. M. Rodocanarhi*, and others of the short-petalled and cupped form. Then, again, in such excessively full flowers, as *La France*, *Maréchal Niel*, *Sou. de la Malmaison*, *Duchess of Albany*, etc., the calyx often spreads out horizontally, a natural result of the continued development and expansion that are steadily going on. It may not happen if the calyx and ovary increased *pro rata* with the number of petals, but this is not always the case. In short, in the early days and the bud stage the tapering flower and thin bloom spread open the calyx much less than do the fat buds over-crowded with petals. At the same time, a quickly expanding flower, like *Fortune's Yellow*, could hardly be expected to expand in its own delightfully characteristic fashion if the calyx remained rigid and erect. If you still further pursue the matter you will find at the ripening of the seed late in autumn that not a few kinds have completely reversed the original position by being reflexed and almost adhering to the stalk or the ovary. We imagine you have a desire to retain the calyx as it clings to the opening bud, and we know full well how much more dressy and beautiful the blooms appear when thus seen.]

Outdoor-sown Asters.—There is no doubted advantage in sowing annual Aster

seed outdoors where wanted to grow, just as ordinary annuals are, because such a sowing gives an excellent succession of flowers to those plants missed under glass and planted out in May. I have found Aster seed thus sown to germinate freely, and the plants bloom freely late. I have also found it grow remarkably well even in great dryness, but the seed was certainly saved the previous year, and English; yet from it came most perfect double flowers. The sowing should be thin—say a dozen seeds in a ring 10 inches in diameter, and one or two in the middle of it, for Asters will not bear crowding. The strains that produce flowers of medium size are best for outdoor sowing, such as the *Comet*, *Mignon*, *Dwarf Bouquet*, *Dwarf Chrysanthemum*, *Quilled*, etc., all really excellent for cutting. A good packet of mixed seed, resting a shilling, will give a wealth of beautiful flowers. A. D.

OUTDOOR PLANTS.

WOOD LILIES (TRILLIUMS).

THIS remarkable genus of North American plants includes a few of the most singular and striking of all hardy plants, but, with the exception of *T. grandiflorum*, all the varieties are considered difficult to manage, this in a large measure accounting for their scarcity in gardens. It is true they are difficult to cultivate if rare

The Large Wood Lily (*Trillium grandiflorum*). From a photograph of a plant by Miss Tait in the gardens at St. Malus, Glencarse, Perth.

not taken to choose the proper position and soil. For instance, to plant even the strong growing *T. grandiflorum* in the ordinary flower border would be a certain way of courting failure. If Trilliums are planted in a properly prepared soil in a somewhat shady situation no fear need be felt as to success. Trilliums require a peaty or vegetable soil, free, deep, and well-drained, as they are most averse to stagnant moisture about their roots. In an artificial bog or by the edge of a pond they thrive admirably when fairly established, and in such positions they are very effective. Their natural element, however, and the position in which we have found them always do best is in clings to such plants as *Andros*, dwarf *Rhododendrons*, *Kalmias*, and other evergreen shrubs, as they are thus efficiently protected from cold winds in early spring. Few plants indeed adapt themselves more readily to shady nooks, and, when once established, they require little or no attention. The stronger growing varieties might with advantage be naturalised in shady woods, and, if this could be managed properly, what a charming picture they would present through the spring months. The best and most useful of the group is the old

T. GRANDIFLORUM (here figured). It grows from 1 foot to 3 feet in height, the large, tri-lobed and handsome leaves being surmounted by large spotless white flowers, borne on short stalks and drooping conveniently so as to show to the best advantage. It blooms

April and May. There is a variety of this called *T. g. roseum*, in which the flowers are suffused with a rosy hue. The flowers are as large as those of *T. grandiflorum*, and the plant is quite as free-flowering.

T. SESSILE has broadly rhomboid leaves, the flowers purple brown.

T. CALIFORNICUM is a large, stately species, flowers pure white with purple blotch, each from 2 inches to 3 inches across. The plant grows to a height of 18 inches. This is a handsome species, and very easily managed.

T. RECURVATUM has oval leaves and small purple-brown flowers.

T. ERETICUM is a common species, with usually brown-purple flowers, varying to white or pink.

Others equally beautiful and desirable are *erythrocarpum*, a most beautiful species, *cernuum*, *ovatum*, *petiolatum*, and *nivale*.

* * * A ROCK GARDEN.

AS ideal rock garden should be sunk. A great mistake is to have a raised one, unless it can be well sheltered both from wind and mid-day sun by a belt of trees. There is one thing in favour of a raised rock garden, and that is, it looks so well looking up at it from below. There certainly should be trees or shrubs near, as a rock garden without a background is not to be tolerated. I am not speaking now so much of alpine gardening as a large rock garden, where shrubs, such as *Cistus*, *Azaleas*, *Ceanothus*, etc., the choicer bulbs and plants, may be massed together, and, with the aid of a well-arranged rockwork, made into a picturesque wilderness; for instance, a large bed, facing north, raised by rocks to some 18 feet, standing well above it, but not in the same bed. Yew-trees form the background of it, over these *Crimson Rambler* and *White Garland Roses* grow rampant, while masses of white *Foxgloves*, *Bocconia cordata*, tall-growing *Snapdragons*, to be followed later by sunny spikes of red *Gladioli*, fill the remainder of this bed. Below this, in a smaller space, is a *Wichuriana Rose*, more than filling its allotted place, its long branches spread upwards and downwards, and are always worth looking at, with their shiny, evergreen leaves in winter, and through the summer and autumn spangled with white fragrant flowers. *Jersey Beauty* and *Barbora*, *Wichuriana hybrids*, also do well, but they are in a more sunny position. Quite at the foot of this nestles a colony of *Oak Ferns*, and here also are the shade-loving *Narcissi Colleen Bawn*, *moschatius* of *Ilwath*, *cernuus*, *pallidus*, *præcox*, and spreading into the grass are *maximus* and *Johnstoni King and Queen* of Spain. In another part a dell leads down to the water garden, of which more another day. The sloping bed on the south-east side of the dell is given up chiefly to bulbs, *Liliums*, dwarf-growing *Bamboos*, *Japanese Impies*, *Enlalias*, *Spanish Iris*, and *Linum catharticum*. In the spring, large clumps of *Narcissus Golden Spar* and *Muscari "Heavenly Blue"* form bright patches, to be followed by *Campanula carpatia* and long-spurred *Aquilegias*, which here do very well and are true perennials, lasting several summers, *californica* especially remaining long in bloom. On the north-western side of this dell a large patch of *Cypripedium calceolus* flourishes in company with *Cyclamen neapolitanum*. Rather raised above this is a bed with rocks implanted in it; here grow the earnest *Saxifragas*, *longifolia*, *Cotyledon pyramidalis*, *Muenchiana*, *ligularis*, *Ajuga*, besides *Dentaria diphylla*, *Uvularia grandiflora*, *Dodecatheons*, and in the cinks of the rocks *Ranuncula pyrenica*. Down by the water a peat bed has been made, in which are grown *Lilium canaliculatum*, *L. pardalinum*, *Erythronium* (the large American sorts), and *E. Hendersoni*, *Vanconveria hexandra* (an *Epimedium*-like flower), *Cypripedium spectabile*, *Primula sikkimensis*. A small bed is given up to *Primula rosea*, the double-flowered *Saxifraga granulata* and *Trillium grandiflorum* forming a background to this, and where it joins a damp gravelly path *Mimulus cupreus* spreads itself in a deep orange glory. *Primula obconica*, in shade, does well grown from seed; the flowers grow in whorls 12 inches high, many of the flowers being single fringed, and lasting in bloom for quite a month. Out-of-doors the *Chamaejasme* much better colour than when

grown inside. In a very sheltered and hot corner (*Eurothera marginata* opens its large, Eucharis-like flowers all through the summer evenings; here also *Ixolirion intaricum* and the *Belladonna Lilies* grow; and from the rocks above first mentioned *Lithospermum prostratum* and *Veronica prostrata* hang in sheets of blue. Last spring a pretty group was made with iris reticulata and *Narcissus cyclamineus*, with a carpet of *Chionodoxa Lucilic-sardensis* was too deep a blue; these all flowered together. It soon mts bright, but in early spring brightness and clearness of colour are wanted. Annuals help to keep up a succession of bloom during the summer months. *Omphalodes luteifolia* and *Phacelia campanularia*, when sown in long drifts near each other, form a pretty combination of colour; whilst *Portulacas*, which here have to be sown in heat, flower well in hot, dry positions. A plant rarely seen now, but which is much to be recommended for the rock garden, is *Linaria repens*—Snowflake I think

niger and viridis, help to fill up the duller months, as in a well-arranged rock garden there should always be something in bloom—some flower to go and look at and enjoy.

ERLYN WHITEHEAD.

Drigh-ton-grove, York.

WHITE PINKS.

FEW flowers have such a well-deserved hold on public estimation as the white Pinks, for it can never be out of place. It is often styled the "common" Pink, but this epithet "common" is in no sense a term of reproach, but rather of honour, since it testifies that its fragrance and purity have earned it a place in the affections of rich and poor alike. It is the "common" things in life that we love rather than the unique and extraordinary. In June the white Pinks in the cottage gardens flood the winding village road with their delicious essence, sweeter than "all the perfumes of Arabia."

often resemble nothing so much as a cartload of clinkers or rough stones shot out on a heap of soil, can, in a short space of time, be transformed into objects of beauty by planting them with white Pinks, which soon shroud their imperfections with a hanging drapery of tender-coloured leafage, thickly set in summer days with numberless fragrant white blossoms.

White Pinks are amongst the most easily-propagated plants in cultivation. If old clumps are taken up and pulled abroad in August, and the sections placed in the ground in an upright position with the whole of the woody stem buried and only the upper tuft of leaves above the soil, they will almost invariably root if trodden in firmly at the time of planting, even if the ground be almost-dry and no rain should fall for weeks. Under such unfavourable conditions the foliage often becomes dry and apparently lifeless, but with the autumnal rains it gradually assumes a more healthy appearance, and the little plants flower the succeeding summer. Where water can be given at planting time, and if occasional welcome showers fall, the leaves show no signs of loss of vitality, and the buried portions rapidly push out roots. Of late years many varieties of the white Pink have been raised, all of which are larger than the old garden favorite. Of these, the best are: *Her Majesty*, a large bold flower; *Mrs. Sinkins*, another fine blossom, but in common with the former, apt to split the calyx; *Albino*, a smooth-petalled variety; *Mrs. Lakin*, also smoother than *Her Majesty* and *Mrs. Sinkins*, and not so constricted a calyx-splitter; *Mrs. Welsh*, large and good, and rather later than the rest; and *Purity*, a well-shaped flower which rarely splits the calyx. S. W. F.

NOTES AND REPLIES.

Hardy plants under glass.—I am very fond of Carnations, Lilies, Roses, Clematis, and other hardy plants, but this bleak and smoky district is a great enemy to successful growth in the open. I have come to the conclusion that something in the nature of an unheated structure will enable me to overcome the difficulties the locality imposes. The question is, what form of structure shall I get? My friends recommend the ordinary straight line greenhouses that joiners and others build. I do not very much fancy them in front of the house, and the elaborate and architectural-looking conservatories have lately, besides being costly, I remember some time ago seeing a greenhouse at York built without wood or putty, known as a "Curvilinear plant-house." It looked very graceful and light, and seemed as if it would not harbour much in the way of pests, and the curves were very charming in a garden. Mentioning this to my friends, one thought it would not be strong enough; another that it would be so light as to constantly need shading, and that it would be cold and draughty, and the glass would rattle in the wind. I shall be glad to know whether such houses are undesirable for my purpose, or whether a lean-to or, rather, a hip-span can be made on that principle?—HARDY PLANTS.

[The curvilinear iron house would, we think, best answer your purpose. If you can erect it against a south wall it will be all the better. Such a house is cheaply built, lasts well if kept painted, and owing to the amount of light is very suitable for plant growing. Take care, however, that you allow plenty of ventilation, this being very necessary in a house for hardy plants.]

Violets in frame. Please say why my double Violets, put into frame in September, are only now flowering well? I can get them out-of-doors now, and wanted the frame-Violets in December. I require the frame, but the plants are so full of bud I do not like turning them out.—G. ZAY.

[It is the outcome of propagation which is at fault. Not a few increase their stock of Violets by dividing the plants that have flowered through the winter or spring, and believe that somewhat larger pieces will make amends for lateness in propagation. It is not so, however. If you desire the flowers in winter, you must insert cuttings made of the single small crowns known as runners or offsets in October or November, and by planting these out in early April in well enriched soil the finest flowering crowns may be secured for frames in the early autumn. Cuttings as suggested develop into fine tufts when a year old, and teem with flower-buds that by reason of their youth and vigour produce high-class blooms. We may publish a short article on the subject in due course.]

Hardy Primulas.—I have been growing some of the better kinds, such as *Sieboldii*, *Japonica*, *lutcola*, *shikimensis*, *californiana*, etc., and as they don't seem to make very good progress in the house, I thought of planting out in May. In the garden there are two raised beds of good soil, with large stones in front and some laid on the top. One is in a very sunny, sheltered corner, facing south; the other has a hedge at the back and faces north. Will you kindly tell me which situation is best for those kinds, and also tell if I have no peas, but the beds are made up of rotted turf and leaf-mould.—CAUTION.

REPLY OF THE EDITOR:—The latter will succeed in the

An edging of Pink. From a photograph by Miss Willmott.

the name is, though no one is quite sure of it. It is a mass of small white flowers, growing in spikes, not unlike a Lily of the Valley, a foot high, flowers all through the summer. The blue variety is not so good as its name indicates; it spreads quickly, but is easily kept within bounds. The paths are edged with *Erysimum pulchellum*, yellow in the spring, and green the rest of the year, with grey *Cerastium tomentosum* for a contrast. Forget-me-nots, Welsh Poppies, and *Linaria alpina* spring up and grow where they will, as long as they do not smother choicer plants.

There are many interesting bulbs to grow in a rock garden, such as some of the Tulipa species—*rizzii*, *Greigii*, *Chusina*, *persici*, *orthanidea*, *saxatilis*, *sylvestris* (the English wild Tulip), *elegans*; and what more lovely than a mass of *Gesneriana* run against a dark background? a Tulip, too, which lasts so long in flower. Autumn Anemones, *Plumbago Lambertii*, *Erica carnea*, *Hellebores*, lch

In ideal pleasures the same fair flowers gleam in the still twilight hours, their scented breath stealing upward to the topmost turret. "Fragrance, as has been well said, is the song of the flowers," and surely few blossoms sound a sweeter music than the white Pink. For edging beds and borders, especially those along whose verge a path runs, the white Pink is invaluable. When blossoming in the summer its countless flowers form a wide snowy riband redolent of the most exquisite colour, and when the flowering season is past, for all the remaining months of the year its cool-coloured, blue-green foliage remains, composed of an infinity of daintily-spiked leaves, to rest the eye upon. When one shudders at the hideousness of the crude glazed tiles so often used in villa gardens to edge a path, one feels tempted to suggest to the proprietor the use of white Pinks which with their veil their ugly formality from the offended eye. So-called "rockeries," which

south bed, but many may do quite well in the shady one. All the kinds named are quite hardy, and would be most unhappy under glass. *Sikkimensis* is virtually a biennial and a bog plant, requiring its root-fibres within reach of moisture. *Japonica* only reaches its largest proportions with similar treatment, but will grow well in any constantly damp, shady place. This vigorous kind prefers rich soil. *Cashmeriana* will be at home in the shady bed anywhere, and any of the Sieboldi set are best in a slightly sunken colony where the surrounding moisture drains thereto. Good rotten manure may be also applied to the soil for these two kinds. *Luteola* should be planted on the higher part of the shady bed, placing a couple of stones to form two sides of a triangle, and planting it in the acute, wedge-shaped portion, slightly raising the plant above the surrounding soil. Plant all quite firmly and water freely all save the last, and this in less quantity. Peat is not at all a necessity, but you may add a good dressing of well decayed manure before planting and dig or fork it in rather deeply. Should you have any fear of the soil becoming dry it will be helpful to place stones around most of the plants, and if your bed is very high or sloping prepare a flat-table for each before planting. In this way the rainfall will settle about the plants and not run away.]

INDOOR PLANTS.

PROPAGATING CAMELLIAS.

Will you kindly tell me how to take cuttings of Camellias, and when is the best time to do so?—H. V. R.

[Camellias are best increased by grafting (Figs. 1 and 2) and inarching (Fig. 3). The months of September and October are best for grafting. Get the stocks into the house a fortnight before the operation. Cut the scion as in Fig. 1, and make the incision as in Fig. 2. Place the graft so that the bark of the scion and the graft will meet at the edges, then tie firmly with matting. If the stock and scion are selected as in Figs. 1 and 2, they will unite quickly and neatly. Put them into a close frame in the propagating house on a gentle bottom-heat. When they have been there for about a month the top of the stock may be shortened to throw the sap into the buds.

INARCHING may be performed in the greenhouse. In the case of a large plant of a good variety which it is desired to increase, erect a temporary stage on which to place the stocks, so that they may not be shaken about. Cut off the bark and a small piece of wood, as shown in Fig. 3, hold them closely together, and bind them tightly with matting or worsted.

Fig. 1.

Nearly three months must elapse before they are cut away, which must be done with a sharp knife. March or early April is the best time for inarching Camellias.]

BORONIA HETEROPHYLLA.

Would you kindly name the enclosed flower, and give me the proper cultivation of it?—CONSTANT READER.

[The name of the specimen is *Boronia heterophylla*, a native of the Swan River district of Western Australia. It first flowered in this country in the spring of 1885 at Kew. The flowers are produced in great profusion, and when in good condition it forms a very handsome specimen. The treatment given to the free-growing section of greenhouse Heaths will suit it well. Cuttings are not particularly difficult to strike if a few simple instructions are carefully carried out. They do best if covered with a bell-glass, therefore the size of

the pot or pan will depend upon the diameter of the glass that is available for covering them. Whatever receptacle is used must be well drained, leaving about 3 inches of space for the soil, which should consist of equal parts of peat and silver-sand, passed through a sieve with a quarter of an inch mesh, and pressed down very firmly, leaving just space at the top for a thin layer of clean silver-sand. The best cuttings are formed of the half-ripened shoots, taken off at a length of a couple of inches or a little more, which should have the leaves removed from the lower portion for about one-third of the total length of the cutting. Then dibble the cuttings in firmly, avoid overcrowding, and, when finished, give a good watering through a fine rose. After this, allow the pot or pan to stand and drain for a little time

Fig. 2.

before putting the bell-glass in position, in order to get rid of any superabundant moisture. Then cover, and place in the shady part of the greenhouse, where, with a little attention in the matter of water and wiping the glass dry every morning, the cuttings will root in about three months. When rooted, pot them off into small, clean, well-drained pots, using good sandy peat, and potting firmly. During the summer they will succeed better stood on a bed of ashes in a coil-frame than anywhere else, but need a greenhouse temperature in the winter. The young plants must have their growing points pinched out frequently in order to ensure a bushy habit. When growing freely they like plenty of water, but this must be in conjunction with thorough drainage, as stagnant moisture is very injurious to them. When shifting into larger pots, rough peat and coarse sand are necessary, and, in potting, this must be pressed down very firmly, at the same time taking care not to bury the old ball of earth deeper than it was originally.

In the case of plants now in bloom, they should, directly the blossoms are faded, be cut back hard—that is to say, leave only about 2 inches of the lower part of the flowering growth. This will cause the plants to push out young shoots, and directly these make their appearance is a good time for repotting. Before repotting, take off a part of the old soil, but do not disturb the roots more than is absolutely necessary. Use pots a size larger than before, and in potting carefully carry out the instructions above given. The plants will in the greenhouse soon become established in the new soil, and by the middle of July may be stood out-of-doors in order to ripen the wood and set the flower-buds for the following season. When outside, take care that they do not suffer from want of water.]

GROWING CACTI.

I HAVE a small coal-burner house, also viney, facing south. In winter sufficient fire-heat is given just to keep out frost from Pelargoniums, etc. Can you kindly suggest a few Cacti which may be grown in above houses, from whom I can get such, also method of culture? I should like to raise seeds of the same also.—F. POWLER WARD.

[The following Cacti would succeed under the conditions you name, provided they are not shaded at any season of the year, except when in flower, and it is then necessary, as the blossoms last longer than where they are fully exposed to the sun. *Cereus polycephalus*, *C. Mollisonii*, *Echinocactus bicolor*, *E. brevis-*

matus, *E. cornigerus*, *E. Le Contei*, *E. Orcutti*, *E. Ottomii*, *E. texensis*, *Echinocereus Berlandieri*, *E. cespitosus*, *E. Emoryi*, *E. emme-nanthus*, *E. pectinatus*, *E. viridiflorus*, *Echinopsis Eyresii*, *E. multiplex*, *E. turbinata*, *Mammillaria angularis*, *M. cornifera*, *M. decipiens*, *M. echinata*, *M. gracilis*, *M. pusilla*, *M. stello-aurata*. Most of the above are remarkable for their curious yet regular shape, while their blossoms are also attractive. The showiest of all the Cactus race from a floral point of view are the *Phyllocacti*, the varieties of which will succeed in a greenhouse. There is a great number of different forms. Of the other kinds above enumerated we do not know of any nurserymen who make a speciality of them, except Messrs. Canuell, of Swanley. The soil best suited for the different kinds of Cacti is good loam lightened by an admixture of sand and brick rubble broken about the size of Beans. When potting is necessary, it should be done in March or April, but one thing to bear in mind is that most of this class thrive best when pot-bound, hence care must be taken not to overpot. From this time to the end of August the soil must be kept fairly moist, after which less water should be given in order to ripen the growth, while throughout the winter months they should be kept quite dry. The *Phyllocacti*, being of a less succulent nature, must not be dried to the same extent as the others, but even these need very little water during the winter.

Most of the different kinds of Cacti can be raised from seed without difficulty; that is, when good seed can be obtained. Sow in well-drained pans in a mixture of loam and sand, sprinkling enough soil over to thoroughly cover the seed, but no more. The seed-pans are best stood in a warm, shaded structure, and the soil must be kept slightly moist at all times. Under such conditions the seed soon germinates, and, if sown in the spring, the young plants will attain sufficient strength to pass the winter without injury. When large enough to be conveniently handled, the seedlings must be put singly into small pots, taking care that good drainage is ensured.]

NOTES AND REPLIES.

Name of bulb.—In April 5th number, "Self" asks for the botanical name of bulb belonging to *Arum* family, grown only in warmth, without soil or water. The name is, no doubt, *Saurostatium* (syn. *Arisema*) *guttatum*—DORA ALLISON.

Asparagus Sprengeri.—Kindly state if *Asparagus Sprengeri* is the same as *Asparagus decumbens major*.—R. T. WOODS.

[*Asparagus Sprengeri* is totally different from *Asparagus decumbens*. We do not know A.

Fig. 3.

decumbens major. By far the more ornament of the two is *A. Sprengeri*, with woody climbing stems clothed with flat, shining, bright green leaves, each about an inch long and the tenth part of an inch or thereabouts in width. This species has become exceedingly popular of late years, as the foliage retains its brightness, even when exposed to cold draughts, hence it is frequently employed for the embellishment of the dwelling-house. *Asparagus decumbens* is altogether a far more fragile plant, the slender drooping shoots being clothed with small linear leaves of a rather a greyish shade of green. It is seen at its best grown in a suspended basket, and when in good condition has an extremely light and elegant effect. This forms a cluster of tuber-like masses, from whence the

shoots are produced. It is more particular in its cultural requirements than most of the ornamental forms of Asparagus.]

Treatment of bulbs.—I am growing the following plants indoors—viz., Begonia (tuberous), Gloxinia, Solomon's Seal, Lilium candidum, L. longiflorum, and L. tigrinum. Will you kindly inform me whether the correct treatment of the above, after blooming is over and the leaves are beginning to decay, is to gradually withhold water, and when the soil has become dry to store the pots away in frost-proof quarters until required for re-starting again, giving no water all the time they are stored? (Before re-starting them should they be repotted, and, if so, should the old roots be cut off?—ANON.)

(The various plants that form the subject of your inquiry will not after flowering all conform to one mode of treatment. The Begonias and Gloxinias should be treated exactly as you state, and before re-starting them they must be shaken quite clear of the old soil. You will find that when the time for repotting comes round nearly all the roots will have perished, but if there are any still attached to the tubers cut them off. The Solomon's Seal is perfectly hardy, and succeeds much better when planted in the open ground than in pots; hence, the

will need much the same treatment as *L. longiflorum*. These Lilies are, when growing under glass, particularly liable to be attacked by green-fly. These pests shelter themselves among the unfolding leaves, and must be carefully sought for they work considerable havoc before they are noticed. Dust the leaves with Tobacco-powder if the pest appears.]

NATURALLY-GROWN HYDRANGEAS.

I grow the Hydrangeas from cuttings taken about March, struck in a little heat, and potted into a 5-inch pot with much the same compost as I use for Geraniums, etc. They generally have one head of bloom the first season, and have weak liquid-manure as soon as the flower shows. When done blooming, the plants are plunged outside in a moderately sheltered place, and left till the following spring, when they are repotted if they have grown much; if not, they are well fed. They soon branch out and make nice plants. I seldom prune them unless the shape is ugly. They are grown on

good deal of sunshine, but at the same time it is better if the sun's rays are broken during the hottest part of the day. Careful attention to watering is, of course, necessary.]

Clematis *indivisa lobata*.—I planted one of the above in my lean-to conservatory early last year. It grew rapidly till it covered the wall, but in September the leaves came off, with the exception of a few at the top (still on), and no new ones have replaced them, although at each joint small buds appeared a month ago, but remain in a stationary condition, though full of green sap. The only life is in the shape of green shoots sprouting from near the roots. Can you tell me what is wrong?—A. E. HARRISON.

[We fear that your failure is due to allowing the plant to become dry at the roots. The cultural requirements of this Clematis are very simple. Plant it in a compost of loam, peat, and sand, give it a fair root-run, and, above all, do not stint the water supply, but at the same time see that the drainage is perfect, as stagnant moisture is quite as harmful as dryness. It needs very little pruning, unless to keep it within a limited space. Loose training adds to its beauty, as the branches of *liliana* hang gracefully at some distance from the glass roof.]

Cinerarias failing.—I have grown Cinerarias for a number of years, but have not been successful these last two seasons. They do well until I get them into their flowering-pots, and then they start to droop, and in a few days are gone altogether, and may be lifted out of the pots with only a little surface soil, although the roots have worked their way round the cracks at the bottom. I saw about the first week in May, and prick off as soon as large enough to handle into 30-pots, then into 4-inch, from them into 6-inch, and, finally, 7½-inch or 8-inch pots. I use a compost of half loam and half good Beech leaf-soil, with a small quantity of sand and a little rotten manure, and a liberal supply of bonum meal for the two last shifts. I shade during bright sunshine, and give the necessary syringings, and always keep them clean from fly.—R. W. W.

[As your Cinerarias keep in good condition till they have received their final shift, it follows that the fault must be sought for in that operation, and in our opinion it lies in an excess of stimulants. For a final shift, we prefer two-thirds good turfy loam to one-third leaf-mould, with a little manure and sand, and trust to stimulants in the shape of weak liquid-manure after the roots have thoroughly taken possession of the new soil. The general treatment as detailed by you should yield very satisfactory results, and if you omit the bone-meal and pot moderately firm, we do not think you will have any further cause for complaint. Of course, the watering must be carefully done, particularly in the winter and early spring.]

Deutzia *gracilis* failing.—I should be grateful if you will tell me why I have failed with *Deutzia gracilis*, and why blossoms come as enclosed instead of expanding properly? I have failed two years with it. It is grown in pots brought in from outdoors end of December, not placed in heat, but kept in glass porch facing south, daily syringed with tepid water till foliage is well advanced. Seemed healthy and going on well till the blossoms spread open half developed, as you will see, and no good. Have stood now outdoors in sheltered place. *Azalea mollis* has done excellently under same treatment.—J. W. HARDY.

[A severe check of any kind will cause the flowers of *Deutzia gracilis* to go blind in the way of the enclosed specimen. Again, if lifted from the open ground and potted for forcing they are very liable to behave in a similar manner if the roots have not taken a good hold of the soil before they are removed under glass. There is yet a third cause, and that is, insufficient nourishment during the preceding summer and autumn, when the plant is making and perfecting its growth. At that period a good sunny position and occasional doses of weak liquid-manure are very essential to the future display of blossoms. *Deutzias* that have bloomed in pots, and are intended for the same treatment, should, directly the flowers are over, have the old and exhausted wood carefully thinned out, in order to encourage the formation of young clean shoots. Repotting, if necessary, must be done then. As the foliage produced under glass is very delicate, the plants must be protected till all danger from frosts is over, after which they may be placed outside. We have carefully read your account of the treatment given, and cannot see any weak point in it, hence have come to the conclusion that the cause of the failure was the treatment during the summer and autumn preceding.]

Heliopsis failing.—I should be much obliged if you would kindly tell me why the leaves of a *Heliopsis* plant turn brown and fall? The plant is a rather large one, and about 1½ feet high, from a main stem it was thick and bushy, but now it is straggling, the long branches being thin and comparatively few-leaved. The plant is in flower. Would you advise me to cut the stems back when the flowers fade, and will you also say if *Heliopsis*

A naturally-grown Hydrangea. From a photograph by Mrs. Hughes, Dalchoholm, Co. Down.

usual method is to dig up the roots in the autumn, select the strongest for potting, and employ them for greenhouse decoration; then, after the flowers are over, plant them out again. If kept altogether in pots they must not be completely dried up at any time, though, of course, less water will be needed when totally dormant than when the plants are in active growth. *Lilium candidum* had better be planted out and allowed at least a year to recover itself, as it is not very amenable to pot culture. The white Trumpet Lily (*Lilium longiflorum*) should after flowering be stood out-of-doors and given less water than before. When dormant, which will, as a rule, be about the middle of September, it should be repotted, taking away as much of the old soil as can be done without injuring the roots. After potting, it may be stood in a sheltered spot out-of-doors till sharp frosts make their appearance, when it had better be placed in a cold-frame. The roots are active throughout the winter, hence the soil must not be allowed to get too dry at that time, but as the flower-stems develop, an increased amount of water will, of course, be necessary. *Lilium speciosum rubrum*

from about the beginning of April in a cool-house. This soil seems particularly well suited to them. They grow most luxuriantly outside, and the flowers are generally very blue; but those in pots are always pinkish, and last in a room for weeks. M. HARRIS.

Dalchoholm, Co. Down.

Fuchsia *fulgens*.—I have had a plant of this for three years, but it has not yet bloomed. It is now in an 8-inch pot, and is making some rather weakly growth. Ought it to be cut back and repotted? It made good growth last year, with splendid foliage, but no flowers. It is trained flat on a wooden trellis, and is at least 3 feet high.—A. H. BARNEMOUTH.

[There is no apparent reason why your plant of *Fuchsia fulgens* did not flower in a satisfactory manner last season; perhaps it was too much shaded. It should now be cut back into shape, and as soon as the young shoots commence to push after this the plants should be repotted in a mixture of loam, leaf-mould, well decayed manure, and sand. Presumably it is now in the greenhouse. If so, you might, when repotted, be gradually recovered from the potting, and taken out of the new soil, plunge it out-of-doors, preferably in a spot where it gets a

will bear liquid fertiliser? Any advice will be gratefully received, as I have been very unlucky with Heliotropes, and should greatly like to grow them well. The plant is in a sunny greenhouse, where the temperature ranges from 50 degs. to 65 degs.—H. J.

[Your Heliotrope must have received some check to cause the leaves to turn brown and drop, but the reason of it we cannot say. The foliage of the Heliotrope is delicate, and quickly suffers if the plant is allowed to get too dry or too wet at the roots, while fumigation with Tobacco-paper will cause the leaves to curl up, turn brown, and ultimately drop. Again, a single day of the sulphur-laden fogs such as dwellers in the London district are far too familiar with during the winter will burn up the leaves of the Heliotrope as if they had been exposed to fire. You speak of the plant being thick and bushy when you first had it, which was probably last summer, at which season the Heliotrope grows freely enough, but many fail to keep it in good condition throughout the winter. To succeed with it at that season it needs a minimum winter temperature of 50 degs. Your better way will be to cut the plant back into shape, and as soon as young shoots make their appearance repot it, not necessarily into a larger pot; indeed, it is very probable that you will be able to remove so much of the old soil without injuring the roots that a smaller pot will suffice. In a few weeks, however, you will be able to purchase young and vigorous Heliotropes at a very cheap rate, which will grow with less trouble than your old stunted plant. Heliotropes will bear weak liquid-manure when they are growing freely and the pots full of roots.]

CHRYSANTHEMUMS.

CHRYSANTHEMUMS FOR DECEMBER.

I SHOULD be much obliged for cultural instructions as to the growing of the following Chrysanthemums: Jane Motganeux, Mrs. Barkley, John Shrimpton, Mrs. White Popham, Edith Tabor, Lord Brook, Le Grand Duc, Mrs. Mease, H. J. Warren, R. E. Pearson, Robert Farnell, and Mme. Carnot. They are at present in 3-inch and 4-inch pots in a cold-frame, and are nice, healthy plants. I am anxious to have good, bushy, tree-flowering plants to bloom in December or rather earlier.—ANXIOUS.

[The varieties mentioned in your somewhat brief list are not so well suited for the purpose under notice as could be desired, yet, if you will treat them as we advise, there is no reason why you should not have nice bushy, free-flowering specimens to bloom in December next or earlier. You say your plants are now in 3-inch and 4-inch pots, and, that being so, they are in a nice forward condition. You are doing quite right to keep the plants in a cold-frame, and, provided you freely ventilate the cold-frame, the plants should make satisfactory progress for the next few weeks. Assuming that your plants are now well established in the pots just referred to, and that they are some 6 inches to 8 inches in height, they should be pinched or stopped to induce a bushy habit of growth. Pinching is accomplished by taking out the point of the shoot of each plant, and, within a week or ten days subsequent to this operation, new lateral shoots should be seen developing in the leaves immediately below the point where the pinching took place. By keeping the plants rather dry at the roots for a week or rather more after the pinching has taken place, the formation of the new lateral shoots is assisted to some extent. Take up as many strong shoots from this point as each plant appears capable of supporting, and grow on with all possible vigour. Never pinch the plants and repot them at the same time; rather allow some ten days to elapse between the respective operations. As each of the new shoots attains a length of some 6 inches to 8 inches repeat the operation of pinching as first carried out. Each succeeding 8 inches of growth should receive similar treatment, giving the last pinching about the middle of July. The shoots forming as the result of this last pinching should develop what are known as terminal-buds, these buds marking the termination of the plant's growth. We should be disposed to remove all buds, from the cluster forming at the apex of these terminal shoots, except the largest and best shaped one. Having pinched your plants several times during the growing season, they should each produce a fine display, because of their bushy character. You will also have the advantage of producing a bloom of

goodly proportions, and each one on a stout, erect footstalk. Most of the varieties in your list are strong-growing, and, to grow them well, the pots in which they are to be flowered should be quite 9 inches in diameter. A few of the stronger rooting kinds would be better in 10-inch pots. Treated in the manner we have prescribed, the period of flowering should begin in the latter part of November.]

CHRYSANTHEMUMS—STOPPING AND TIMING.

(REPLY TO "ENOR" AND "CONSTANT READER.")

THE season is rather far advanced to think of pinching the plants with the object in view of securing second crown-buds. In the list, however, we have recommended second crown buds where this is possible by an early pinching; in other cases, we have no option but to advise a first crown bud selection.

Name	When to pinch the plant.	Which buds to retain.
Pride of Stobell	Natural break	First crown
Souvenir de Mons. Menier	Natural break	Any buds in late August
Pride of Ryecroft (Yellow Niveum)	May 7th	First crown
Niveum	May 7th	First crown
Charles Davis	Natural break	Any buds in late August
Wm. Tricker	Natural break	Any buds in late August
Soleil d'Octobre	Natural break	Any buds in late August
W. H. Lincoln	Natural break	Any buds in late August
Mme. G. Brunnant	Mid-April	Second crown
Mlle. Marie Hoste	May 7th	First crown
Sour. de Petite Anie	Natural break	Any buds in late August
Mme. Carnot	Mid-April	Second crown
Commandant Hisset	May 21st	First crown
Lady Hanham	Natural break	Any buds in late August
Mme. C. Capitain	Mid-April	Second crown
Miss Nellie Pickett	May 21st	First crown
N.C.S. Jubilee	Mid-April	Second crown
Rol des Precoees	Natural break	Terminal
Ryecroft Glory	Natural break	Terminal
Richard Dean	May 21st	First crown
Source d'Or	Natural break	Terminal
Enterprise (Jap. Anem.)	Mid-April	Second crown
Mrs. Hume Long	May 15th	First crown
The Queen	May 7th	First crown
Princess Victoria	May 21st	First crown
Alberic Laurent	May 21st	First crown
Mlle. Therese Rey	May 15th	First crown
Blouie du Rocher	Mid-April	Second crown
Mrs. W. S. Trafford	Natural break	Any buds in late August
Mons. J. Allenzel	Mid-April	Second crown
Mons. W. Holmes	Natural break	Terminal
Lillian Bird	May 21st	First crown
Colonne d'Or	May 21st	First crown
Mrs. D. Ward	May 21st	First crown
Elthorne Beauty	Mid-April	Second crown
Mme. E. Roger	Mid-April	Second crown
Pearl Wray	May 21st	First crown
Voltaire	May 10th	First crown
Marie Calvat	Mid-April	Second crown
Sunstone	May 15th	First crown

NOTES AND REPLIES.

Treatment of Chrysanthemums.—I have a collection of healthy young Chrysanthemums of the best kinds in 5-inch pots about 9 inches to a foot high, and have pinched out the points of the plants, as directed on page 63 of GARDENING ILLUSTRATED for the 29th March. Will you kindly inform me whether these young plants should receive any nourishment at this early stage, what is the best food to give them, and how frequently they should be fed? I propose to shift the plants in the course direct into 9-inch pots. Will you kindly say what is the best preparation of mould for the 9-inch pots? I have some old leaf-mould, some decayed sods, and sand. Is a mixture of these ingredients the best, or can you suggest a better preparation?—A. M. M.

[No, do not feed until the plants are in their flowering-pots, which must be well filled with a final rotting compost use three parts fibrous loam, one part leaf-soil, and one part well-rotted horse-manure. See reply to "Anxious" on this page.]

Chrysanthemums—stopping and timing, etc. (Enor, Yorks).—In all cases where we have advised that a plant should be left to make a "natural break," and this has not taken place before the end of the third week in May, you had better pinch out the point of the plant, and flower the resulting shoots on the first buds which they subsequently develop. So far north as Yorkshire, we should not advise that the second "crown" buds be secured on plants pinched so late as the period mentioned in May. Those sorts in your list which are specially suited for bushy plants of a free-flowering character, as described on page 63 of GARDENING ILLUSTRATED, are the following: William Westlake (the best variety), Pompon, Yellow Niveum (Pride of Ryecroft), Niveum, Charles Davis, William Tricker, Soleil

d'Octobre, Rol des Precoees (October-flowering), W. H. Lincoln, Souvenir de Petite Anie, Lady Hanham, Mme. Carnot, Source d'Or, Ryecroft Glory (October-flowering), and N.C.S. Jubilee. All the foregoing are Japanese varieties. We should be disposed to feed the white sorts cautiously, as many of these appear to be susceptible to damping. Any nurseryman's catalogue should give a full description of the colour of each variety.

GARDEN PESTS AND FRIENDS.

VIOLET DISEASE.

OWING to the great increase last season of Violet disease, the question of protection against attack and consequent loss of crop demands the attention of market growers. Home-grown Violets always command good prices, their fragrance in itself being sufficient to place them far in front of those imported from the Continent. In Violet culture we have a good opening for increased supplies of the home-grown article without much danger of any falling off in prices, yet this year, in many cases, buyers were unable to satisfy the wants of their customers, and had to rely to a great extent upon French and other foreign Violets. This state of affairs was no doubt partly due to the ravages of the "spot" and other diseases, I fear that none of the various so-called remedies against the fungi are of the slightest use at least, that has been my experience after careful and constant trial. My chief object in writing this is to bring the subject to the notice of growers, in the hope that those who have been troubled by any of these fungi may relate their experiences, giving also the particular conditions which favour the cause and development of Violet disease. Spraying, except with some really effective fungicide (and this has yet to be discovered), would, in the case of market growers, cut down the profits to an unremunerative level. Soil and climate are varying factors, and may have much to do with the greater prevalence of the disease in some districts than in others. One grower, writing to me from Ware, Herts., states that in the light gravelly soil of his garden he finds it almost impossible, on account of the disease, to grow Violets, even with constant attention and spraying, whereas in Wilts and Hants, where he formerly resided, and where the soil was heavy, his plants were not liable to disease. No doubt some varieties are more disease-resisting than others, and among the fifteen varieties I cultivate (including many thousands of plants) I found this notably so in the case of "John Collins," a good autumn-blooming variety whose thick medium-sized leaves seemed to repel the attacks of the fungus longer than the larger and more tender-leaved kinds, such as La France, Princess of Wales, Luxonne, etc., but in no case did any variety prove invulnerable. It has frequently been suggested that over-feeding may be a cause of this disease, and this, no doubt, is true in some instances. Referring to the above, Dr. Cooke, of the R.H.S. Scientific Committee, says: "We believe this is so, yet we had it (the disease) in a poor soil with no manure added."

Those who are not familiar with the appearance of Violet disease may recognise it in its early stage by the formation of small, orbicular spots on the foliage. Spores drop from the leaves to the ground, where they remain for some time, continue to grow, and eventually inoculate other bays. It is, therefore, apparent that any fungicide, to be thoroughly effective, should, without injuring the plants, be yet sufficiently powerful to render the germs in the leaves inert, and by acting directly on those hidden in the soil, prevent the latter from doing further damage.

In November, 1900, I first noticed spots on a few plants (La France, Victoria, and Luxonne) which were growing on the same bed. I promptly removed and burned the affected leaves. This had to be repeated several times, and the plants which were first attacked succumbed, but the others recovered sufficiently to flower during the spring, and apparently regained a healthy condition, the foliage of all my plants then, and at the planting season in April, being strong and free from any signs of disease. In June, however, I noticed a return

of the disease amongst young plants situated about 30 yards from the previously affected stock. I had the leaves immediately gathered and burned as before, and this was frequently repeated, nevertheless the fungus rapidly spread to other Violet plants, and appeared in new plantations 200 yards to 300 yards distant. In July I tried spraying with Bordeaux-mixture, and had this repeated several times at intervals of a fortnight, subsequently substituting an ammoniacal solution of carbonate of copper. Finding no beneficial effects resulted from this treatment I then tried a solution of potassium sulphide (1 lb. in 50 gallons of water), and the latter proving equally inefficient, the beds and plants were finally watered about once a week with potass. permanganate (1 part in 2,000 of water). This was applied three times. Throughout the entire season all diseased leaves were picked off, consequently, towards the approach of autumn, many of the plants were deficient of foliage, while others had been destroyed by the fungus itself. The summer in this particular district was a phenomenally dry one. The plants in the driest situations suffered most, but towards the end of the season, when the heat became less and more rain fell, the disease, though still conspicuous, did not seem to be so active. I found that the more gathering of diseased leaves, diligently persevered in, and combined with partial shading during the hottest weather (using brambles for this purpose), was productive of better results than any of the various spraying solutions I tried, and the plants thus treated were the only ones to produce anything like a bloom during the autumn.

The question of infection being carried through the air, and not being dependent upon contact alone, is an important one. That this is the case will, I think, be shown by the fact that fresh and healthy plants, which I procured from Surrey in September, and which were planted at least 100 yards distant from any affected plants, showed signs of the "spot" very shortly afterwards. Every care was taken to isolate the plants during unpacking and other stages. It would be interesting to have the experience of other growers who have suffered from this disease, and whether in any case the culture of Violets has been successfully resumed; if so, what length of time was allowed before recommencing? I think that once the fungus has become established, any attempt at replanting will be useless, unless all former plants are destroyed and a certain length of time allowed to elapse in order to "starve out" any germs which might be latent in places other than the soil itself, and whose presence would cause a return of the trouble. To show that Violet-growing has already actually become impracticable in certain places, I quote the following from a pamphlet published in 1900 by the United States Board of Agriculture: "This disease (Alternaria Violet) is one of the most widespread and destructive maladies known to attack the Violet. The cultivation has been given up in many sections of the country, owing to its ravages. Five or six years ago 50,000 to 75,000 square feet of glass near Alexandria, Va., were devoted to the cultivation of the Violet, but the industry has been

practically abandoned." So far, the disease seems to have committed havoc only in certain districts, but, owing to its peculiar characteristics, a further spread seems inevitable unless suitable preventive measures can be discovered and adopted.

HENRY T. HUTTON, F.R.H.S.
Donaghadee, Co. Down.

NOTES AND REPLIES.

Destroying ants.—Will you kindly tell me how to deal with ants? A friend of mine has a Strawberry-bed under a stone wall. Last year there was a magnificent promise of fruit, but none ripened, as the ants destroyed the whole crop. What can be done to keep them away from the bed?—BARROWBY.

[As regards getting rid of the ants near your Strawberry-bed, the first thing to do is to find out the exact position of the nests, which, I imagine, are situated at the foot of the wall, and perhaps partly under the foundations, then dig down until you reach the nests, and soak them thoroughly with boiling water, or a fairly

of which are very injurious to plants. The worms were very active when they reached me, but I found that they were killed in about five minutes by soaking the soil with common lime-water. Of course, this does not prove that they may be killed as easily when they are in the ground, where the lime water would more easily drain away from them, but it would be worth while trying what a heavy watering would do. Put some fresh lime into a tub, say 4 lb., and pour 8 gallons of water on to it; stir it about well, and let it stand for forty-eight hours, then use the clear liquid without disturbing the sediment. It would be well to experiment on a small scale at first, so as to be quite sure that the watering does not injure the plants the worms are feeding on.—G. S. S.

Apples injured.—Can you please tell me the cause of my Apples last season being positively riddled with holes and containing small white maggots, giving them the appearance of rust? Would you please suggest a remedy?—H. L.

[Without further information as to the time of year that the Apples were attacked, the condition of the fruit, whether hollowed out by the maggots or not, etc., it is quite impossible to suggest a remedy. One would imagine that the maggots were those of a fly, but it is a mere guess on my part. Please send as much information as you can, and I will gladly do my best to tell you what the pest is and the best remedy.—G. S. S.]

Vine-weevil destroying Ferns. I shall be much obliged if you will inform me whether the beetles that I enclose are responsible for the heaps of young Maiden-hair fronds that are cut off just after they have begun to expand, and strew the soil all round the plant? The ravages of some pest got so bad that last night in my fernery I got rid of the enclosed, on Adiantum chiefly, although others, *Pteris* and *Platycentrum*, are badly hit too. I used to blame woodlice, but feel sure the enclosed are the culprits. Please tell us their name, and whether there are other ways of trapping them besides hunting after dark with a light?—W. STREVENSON.

[Your Ferns are attacked by the grubs of the black Vine weevil (*Otiorhynchus sulcatus*). We are afraid that there is no other way of destroying these grubs but repeating the Ferns, as no insecticide that would kill them could be used with safety to the Ferns. The only practicable way of getting rid of this pest is by killing the parent beetles. They are very destructive to the leaves of many plants, particularly those of Vines and the fronds of Ferns. As they usually feed only at night, remaining during the day under some shelter, comparatively few persons know of their existence. If you suspect any of your plants are being injured by them, you should search for them at night, as they fall off whatever they are on in any way disturbed. It is safer to buy a white sheet of some kind under the plant before it becomes dark, so that when they fall they may be easily seen. Then some two hours after it is dark throw a bright light suddenly on the plant, and the weevils will probably fall down. If they do not, search the plants well, or give them a good shake. It is useful to lay small bundles of dry Moss or hay on the soil of the pots, or in the case of Vines and climbing plants, to tie them on the stems. The weevils find these very convenient places to hide in. These traps should be examined every morning.]

A Fern-bed wall.

FERNS.

FERN GLAD WALLS.

Will some reader kindly tell me how to cover a bare back wall in one of my ferneries? I wish to grow thereon Ferns, Begonias, etc., so that I may be able to get material for cutting, and thus save the plants that I am growing in pots.—N. V.

[To no better purpose can Ferns and Mosses be put than clothing the naked back walls of ferneries, plant stoves, intermediate houses, and conservatories. Not only is a well-furnished back wall very ornamental, but it is also very profitable, a never-ending supply of well-matured Fern fronds being always obtainable. On the wall here figured the Ferns were fixed by means of sections of diamond mesh wire netting and staples. Only a thin layer of soil, principally composed of fibrous loam, was enclosed, and in this small piece of Adiantum cuneatum were planted 3 feet apart each way, with plants of *Nephrolepis exaltata* and *Begonia Rex* interspersed among them. The Adiantum would appear to be quite at home in this position, the plants increasing rapidly in size, the fronds being very numerous, large,

strong solution of carbolic acid in water. It is almost hopeless work trying to trap them; guano or chloride of lime are said to drive them away, but I have not much, or indeed any, faith in these remedies, except on a very small scale. It is best to open the nest when all the ants have retired for the night, so that all the inmates may be destroyed.—G. S. S.]

Insects on Apple-trees.—I send you a small red insect which I found upon one of my Apple-trees. I should be glad to know its name and habits, and whether it is injurious to fruit-trees or flowers?—A. B. GASKELL.

[The small red insect you send is one of the mites (*Trombidium holosericeum*). I do not know that it has any English name. It is in no way injurious to fruit-trees or flowers; in fact, it is decidedly useful in gardens, as it lives on small insects, etc., and is entirely carnivorous.—G. S. S.]

Worms in soil (M. H. Armstrong).—The worms you sent in some soil are nearly allied to the earthworms, but belong to a different family, the Enchytraeidae, some members

of the Violet, but the industry has been

and better seasoned than is the case with those out from less exposed pot plants growing in the same house. One of the greatest difficulties to be contended with in the wall culture of Ferns lies in the fact that they must be kept well supplied with water, and this in many instances cannot be readily accomplished without washing the soil away from the roots. A freely perforated lead pipe is taken along the top of the wall, and this being connected with the water supply, all that is necessary is to turn a tap and let the water trickle down through the soil as long as may be necessary.]

VEGETABLES.

WINTER SPINACH.

(REPLY TO R. W. MANDERS.)

THE plant you sent was quite shrivelled up, and we could detect no insects of any kind. Spinach grown in the open in soil ploughed none too deeply, and in many cases with only a slight dressing of manure, is short and less fleshy than that in good garden soil. On the other hand, it is hardier. Though the plants in the open in the autumn are not so taking in appearance as those in gardens, they are much hardier and will give a much better return. Much of the success with field culture is owing to change of soil, ample space, and freedom from insect pests. The preparation of the soil is the most important detail, and should be undertaken some months in advance of sowing the crop. Where Spinach has failed on previous occasions, vigorous measures to stamp out such pests as grubs and wireworm must be followed. A sprinkling of fine gas-lime is effectual in getting rid of this pest. Fresh lime from gasworks needs careful application. Secure a good hulk, and by exposure for a time there is always some ready for use at short notice. If used in a fresh state it should be broken very fine and allowed to lie on the surface for a few days. It thus becomes pulverised, and is in a more workable state, and incorporates readily with the soil. Another powerful fertiliser and insect destroyer, though a simple one, is wood-ashes. It is a valuable manure in land that has become sick of garden crops. Spread the wood-ashes on the surface before drawing the drills. Soot is equally valuable, and may be used with great advantage. As wood-ashes are none too plentiful in some gardens, a good substitute may be found in burnt garden refuse, and even burnt soil. The best position for Spinach is high ground, not sheltered in any way. As sowing is usually performed early in August, the ground by that date will be in fine condition. If possible, the position selected should have been occupied by a totally different crop. Sowing thinly is advantageous, as the less the seedlings are touched the firmer hold they have. If thinning is necessary, it should be done when the seedlings are very small.

RHUBARB FROM SEED.

In the amateur's garden it is painful sometimes to see what rough treatment is meted out to this useful plant. More often than not it is relegated to some out-of-the-way corner, where never a bit of manure reaches it, and yet a crop of succulent stalks is looked for in their season. The limited extent of the crop often entails harsh treatment by close pulling for the daily needs. In many such cases Rhubarb becomes only an apology for the name, and is, as is only to be expected, unsatisfactory. It is scarcely justice to so useful a vegetable that such treatment should be given, and, to obviate this, seed raising may be recommended as a partial relief and as an alternative course. The present is a good time to carry out this oft-needed reform. There are, however, early and late kinds, Victoria belonging to the latter, and Royal Albert or Linnaeus early. Draw drills about 1½ inches in depth on well-prepared ground, and about 1 foot apart, and sow thinly. In due time young plants should appear, differing in their habit of growth, the usual course being to choose the strongest and best coloured and destroy the rest. The young plants may grow undisturbed the first year, transplanting them in the winter or towards the spring of the next year. An alternative is to

sow on the ground intended for the new addition to the Rhubarb-bed, and simply leave the seedlings to grow on. Even this may need a little spade work in making right irregularities that occur in the rows, for, invariably, it will be found that all the seeds do not grow. Only those that have attempted to dig up established roots know the depth to which the roots go, so that in preparing for sowing or permanent planting it is wise to well dig or trench the ground and incorporate decayed manure with it to at least a foot in depth. Beyond this and keeping the surface clean not much is called for, but on no account should any stalks be pulled the first, and but few the second, year. After that time the seedlings will be as productive, if not more so, than old plants. W. S.

NOTES AND REPLIES.

Broccoli Spring White.—I quite agree with all that "A. W." says of this useful Broccoli, for not only is it early, but very hardy. There are but one or two others in my collection that have proved so hardy, not including even the Late Queen and Model—usually the hardiest of Broccoli. Vanguard is another that comes in about the same time as Spring White, and this, though less hardy generally, gives a succession from the same bed over a good length of time. These both need to be sown during the first half of April. It is a mistake to sow Broccoli too early. April is quite soon enough for the most of them, and the two under notice are no exception to the rule.—W. S.

Staking Peas.—Many growers when they are selecting the kinds they wish to grow inquire as to their height, especially if their gardens are small or they have a difficulty in obtaining supports for them. Much of late years has been done to give us good Peas of medium height. Often when I have been looking over gardens in the summer I have been struck with the large quantity of stakes and the time taken in making these. This may do very well if expense is not a consideration, but I am convinced that by placing the stakes so thickly as some growers do is no advantage. Of late years I have not used them nearly so thickly, and have found benefit therefrom. I run hick cotton from stake to stake whenever the Pea baulm shows signs of blowing through the supports. It is astonishing how quickly a lad will run on this cotton. When the crop is over it is easy to remove it with the stakes. In this way it does not need more than half the amount of stakes. The labour of putting on and cost are met in the reduction of labour in staking. Added to this I find the birds do not like the cotton. Amateurs, especially those in and near towns, would do well to try this method.—J. C.

Large Runner Beans.—Speaking generally, large kinds of vegetables are neither the best nor the most profitable, those of medium size being infinitely best for private use. Runner Beans are an exception. The very long-podded kinds, such as No Plus Ultra and the selections from it, are very productive when grown in rich, deeply-worked soil. When grown thus, they are often seen from 12 feet to 14 feet high, and in this condition they produce very long pods. Last year I counted on some of the stems from five to seven pods in a bunch, and some of these were from 8 inches to 12 inches long. It may be asked where is the gain in these long kinds? They are more easily gathered, and if needed for market they weigh so much more, and they can be gathered of any size the grower may wish. It is doubtful if any kind of dwarf Bean is more productive under good culture in the open garden than Canadian Wonder, and here, too, the pods are large.—J. CROOK.

Photographs of Gardens, Plants, or Trees.—We offer each week a copy of the latest edition of the "English Flower Garden" for the best photograph of a garden or any of its contents, indoors or outdoors, sent to us in any one week. Second prize, Half a Guinea.

The Prize Winners this week are: 1, Mr. J. Cox, 43, Haydon Park Road, Wimbledon, Surrey, for *Oncidium Forbesi*; 2, Mrs. L. Dames, Eldwick, Battenhall, Worcester, for *Weeping Willow* in *Victoria Park*; Bath.

GARDEN WORK.

Conservatory.—Chrysanthemums should now be in cold frames, with the lights off all day and all night, except when frost is expected. Cuttings for producing one flower may yet be struck in a close frame; only very strong cuttings should be taken. When plants are cut down, the tops will make good cuttings for training up with a single stem with one good-sized flower at the top. These make good plants for forming groups, mixed with Ferns and Grasses, either in the rooms or conservatory. When *Deutzias* have ceased flowering, cut them down and grow them on in a genial temperature till growth is completed, then harden off and plunge in *Coccoloba* outside. Such plants will flower abundantly all up the new growth, and also early without much forcing. The two pretty *Brooms*, *precox* and *Andreana*, are lovely plants in the cold-house. *Precox* has a very graceful habit. We have a number in 5-inch and 6-inch pots in a cold-house which have been sown in flower some time, and they are much admired. They do equally well planted outside, and, therefore, many would think it a waste of time and labour in having things in pots that are hardy enough to thrive outside; but a group of plants in bloom in March attracts attention. This is the season for repotting all plants which may require more pot-room, especially those plants which have been pruned back and are now breaking into growth, such as *Eucrysis*, *Indian Azaleas*, *Camellias*, and *New Holland* plants generally. We always use the best peat we can get for these things, mixed with about an eighth part of silver-sand, and pot very firmly. Special attention is given to the drainage, as a water-logged plant might as well be thrown out as to attempt its renovation. It is hardly necessary to attempt to teach an experienced man the rudiments of watering plants in pots, but there are learners everywhere. Next in importance to careful potted in well-drained pots is the proper moistening of the soil. There are cases in which even the tyro could scarcely go wrong. Such things as *Spiraeas* and *Hydrangeas* require frequent and abundant supplies, with occasionally something in it of a nourishing and stimulating nature. We never water a specimen plant without first tapping the pot. The sound is the best indicator of its condition.

Stove.—Use shade sparingly, still certain plants require a little less brightness now the days are lengthening and the sun gaining in power. Ferns, *Oreohids*, and such fine-foliated plants as *Marantas* must have a light shade when the limit of endurance has been reached. Even *Crotons* and *Dracenas*, which require strong light to put on colour, will require a light shade for an hour or two in the middle of the day. The flowers of *Gardenias* and *Stephanotis* soon lose their pearly whiteness if exposed to hot sunshine, and with exposure to hot sunshine comes the difficulty of keeping up the necessary atmospheric humidity, though, of course, this can be done by flooding the paths several times a day. The syringe is a very useful implement when the water is soft and pure, but it does not benefit the plants to be always syringing them. Once or twice a day is sufficient, and at mid-day flood the paths. The plants which are now growing freely must be opened out and given more room on all sides. Young stuff for next winter's blooming will be better now in a low, warm pit, where they can be near the glass, and receive the necessary pinching to induce a bushy habit. Cuttings of *Poinsettias* should be taken when 2 inches or 3 inches long, and inserted in thumb pots in sandy peat, and plunged in a close propagating frame in a brisk bottom-heat. When rooted move to a close, warm pit, where they can be close to the glass.

Early Peach-house.—Avoid crowding the young growth. Perhaps I ought to have written over-crowding, because in well-trained Peach-trees the shoots are laid in pretty close to each other; but it is in over-doing it where mischief is done. All shoots will now be tied in neatly, and the crop of fruit in the best position to receive the full benefit of the sunshine. Often in April we have cold nights and windy days, when the ventilators must be opened with judgment. We want a free

circulation, but we must modify the influx of cold currents when the wind is in the north-east. A little less ventilation and a little more damping of floors and borders will keep matters right. If the inside borders are well drained there is not much danger of overwatering. Leaches, neither are we likely to overfeed if we give two or three good soakings of liquid-manure during the time the fruits are swelling. I have, in renovating Peach borders, often found them too dry, but never too wet—so far, at least, as inside borders are concerned—and when an inside border of any kind gets dry it is almost impossible to thoroughly moisten all parts of it.

Mildew on Grapes may often be traced to over dryness of the borders, and borders made of a foundation of rubble will take many waterings during the season, unless the borders are deeper than borders usually are nowadays. The Grapes of a gardening friend last year were badly attacked by mildew. On investigating the matter he found that the cause was drought, and took measures to thoroughly saturate the border, and this season there is no mildew and the Grapes are finer. Of course there are other causes of mildew; cold currents of air will produce it, as will also a stuffy, badly ventilated condition of the atmosphere; but these are matters which can be easily rectified, and yet the mildew remains if the roots are too dry.

Window gardening.—From the letters which reach us from time to time one can ascertain that there will be a much greater effort made with window-boxes this coming year. White Marguerites, scarlet Geraniums, and blue Lobelias will be run upon, but there are other things, such as Mignonette, Musk, Stocks, and scented Geraniums, that will appeal to some of us. Balsams are rather pretty in a window-box outside.

Outdoor garden.—There is always work among Roses. As soon as the pruning is finished and the young shoots are growing freely, we must keep a sharp watch for insects. First come the green-fly, and later on the worm in the bud and other troubles calling for prompt attention. Tea Roses, in my opinion, do not require such heavy manurial dressings as they sometimes get. Give them leech of soil, as good as can be obtained, and enrich it reasonably, but, of course, do not block out all the sunshine with heavy manurial dressings. If there is any suspicion of wireworm in the Carnation-beds, place traps of Carrots, Potatoes, or French Beans among the plants, and mark the sites with a stick. I believe wireworms will leave pretty well everything for French Beans. I have sometimes taken three or four worms out of a single Bean. Scoop out a hole, place in half-a-dozen Beans, and cover them with earth, placing a stick to mark the site, and in two or three days examine them and kill the insects. If there are any near, some will be in the Beans. To make the borders gay during summer, sow hardy annuals freely and thinly. The large masses are the most effective. Bulls and spring flowers are very bright now. Sow seeds of the Crown Aconite.

Fruit garden.—Melons and Cucumbers in frames must have a genial bottom-heat. Eighty degs. to 85 degs. will be suitable. The plants get stunted in a low temperature, and a checked plant never does much good. Later on, with more sunshine and warmer nights, the conditions are more favourable. For some time yet warm coverings over the glass must be used at night. Strawberries are coming forward in cold-houses now. These do well on shelves in the Orchard-house. For late fruit, the plants should be in 6-inch or 7-inch pots, as in small pots watering is a difficulty, and if not well attended to there will be deformed and hard fruit. Some of the healthiest of the forced plants of Royal Sovereign or Vicomtesse H. de Thury may be planted out for a late summer and autumn crop. To have fine fruits, the blossoms should be thinned. A dozen fruits are quite enough to leave on a strong plant. There will be a good deal of work now in the vinerias, especially where early and late foreign is carried on. The young shoots, even after they are stopped and tied down, will require looking over to keep the sub-laterals in check. These shoots

must not be permitted to disorganise root action. The best time to feed Vines with quick-acting stimulants is just as the berries have about finished stoning. Of course, Vine-borders should not be permitted to get dry at any time. Drought is a frequent cause of mildew and cracking of the berries.

Vegetable garden.—Plant out Cauliflowers which have been raised in heat. Leeka and Brussels Sprouts, which have been raised in boxes under glass, should be pricked out into nursery beds 8 inches apart. Onions raised in heat and hardened off may now be planted out in well-prepared ground in rows 1 foot apart, and 6 inches apart in the rows. We have had very good crops of Onions pricked out between rows of spring-planted Strawberries. The latter were planted solely for runners first season, and the Onions paid for labour. Tomatoes for outside planting should be grown cool and sturdy; of course, safe from frost. It is not often there are any spare glass frames at liberty at this season, but if there are, they may be placed over Asparagus-beds; there will then be no break between the last of the forced grass and the earliest from outside beds. For the most part Asparagus planting will be over, but I have planted right up to the end of April with success, though the plants received one or two waterings at first to encourage root action. Mushroom-beds should be made outside now; the best position for the summer beds is in the shade of a building or a wall. Sow dwarf French Beans under a south wall where protection can be given if necessary. A few Runner Beans may be started in boxes to be planted out later. E. HORDAY.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

April 21st.—Sowed Chinese Primulas in sandy pent in pans, covered with squares of glass, in a warm pit. Pricked off a lot of seedling Musks and other Mimuluses. The spotted kinds are very pretty for planting in shady borders; they thrive well in box outside north window. Planted out a lot of forced bulbs, chiefly Narcissi, Tulips, and Hyacinths. Divided and replanted a lot of Cross-pink Jenny (*Lychnis alba mammulata*); it has a pretty effect hanging over the edges of stones or in the rock garden.

April 22nd.—Cut up remainder of Dahlia roots to single buds or young shoots, and potted them singly in 4-inch pots placed in pit, where there is a little warmth just to give them a start. Planted more Peas and Beans, including the dwarf French Bean No Plus Ultra. The last is planted in the warm border. Pricked off Stocks and Asters in frames. Put in cuttings of a new Heliotrope and other things. For the most part the propagation of bedding stuff is finished, as our stocks are complete.

April 23rd.—Gave the Strawberry plantations a further hoeing as a preparation to mulching with long stable litter. Plants are looking well, but three years is the extreme limit of age permitted, so there is no time to wear out. We are moving bedding plants to cold-frames, but they are covered up with mats at night. Sub-tropical and a few other tender things are kept in a house where a little heat is given, as they are wanted strong when turned out. A new border on a south aspect has been made for Figs; a good foundation has been made.

April 24th.—Peach wall is looked over frequently and a few forerights removed from the trees, but we are rather chary of doing much disshidding till the wind is warmer. Insects are dealt with promptly with Tobacco-powder. This is the best remedy, and it may be used whilst the trees are in bloom if the flies appear so soon. Shifted on a few of the forwardest of the Cyclamens. The soil used for young plants is very turfy loam rubbed through half-inch sieve, and the remainder equal parts leaf-mould, peat, and sharp sand. A rather stronger compost will be used for later shifts.

April 25th.—Looked through conservatory climbers to regulate growth. Prunus triloba is in flower now in the shape of good-sized bushes. The plants have been brought on cool,

though when required early it forces well. There is plenty of flowers, but the buds are over and cleared away, and for the most part planted out, with the exception of Freesias, which are kept in a greenhouse and the growth helped a little with liquid-manure. This seems to finish off the growth properly and gives strength to next year's blossoms.

April 26th.—All seeds sown now and generally through the spring are first dressed with red-lead, and neither birds nor mice will touch them. The process is very simple. The seeds are emptied into a dish or saucer and slightly damped, the red-lead is then sprinkled thinly over them, and they are stirred with a stick until all have taken on a coat of lead. Of course, after sowing Peas or any other seeds dressed with lead, the hauls are washed as soon as sowing is finished, as red lead is a poison.

BIRDS.

Death of African Fire Finch (*Zitella*).—The internal organs of this pretty little bird were in a very unhealthy condition, and the immediate cause of death was apparently a wasting disease of the liver. Canary and Millet seed is the proper food for all the Waxbill family, of which the African Fire Finch is a member, and is known also as the Red African Waxbill. As, however, Canary seed is of a stimulating nature, and, if given in quantity, liable to cause liver trouble, it is safer to let Millet form the staple diet of these birds. Both white Millet and spruy Millet may be given, and green food supplied freely in warm weather, but only sparingly during the winter months. The flowering stems of Grass are good for these birds. The Fire Finch requires to be kept in a somewhat high temperature, and will not breed freely in a lower temperature than 70 degs.—S. S. G.

Canary ailing (*H. Bates*).—There was no chance whatever of your bird ever recovering from the complaint from which it was suffering, so you did well in putting an end to its life. You give no particulars whatever as to the feeding and general treatment, but the bird was exceedingly thin, consisting chiefly of feathers. This wasting disease is very frequent among cage-birds, being often brought about from their being supplied with unsuitable or insufficiently nutritious food, although a bird so affected will sometimes live for months, eating ravenously, as in this case, but becoming gradually weaker. The only chance of effecting a cure is by taking the case in hand at the early stages of the complaint, making an alteration in the diet, and so forth. It is well to remember that no seed-eating bird can possibly remain in health for any length of time without a constant supply of sharp grit to assist the gizzard in the digestion of the food.—S. S. G.

LAW AND CUSTOM.

Notice to quit.—I took a house on Oct. 14th, 1899, as a yearly tenancy, without a written agreement. I gave notice on March 24th to quit on Oct. 14th next, but my landlord (a solicitor) informs me that my tenancy is a Michaelmas one, and that my notice is bad. Can I quit on Oct. 14th next, or shall I have to give notice next March to quit at Michaelmas?—H. E. S.

[You may have entered on October 14th, but what was the term of your tenancy? If you have paid rent as from September 20th, or if you paid broken rent from October 14th to March 24, and afterwards from March 24th and from September 20th, your tenancy is from Michaelmas, and the notice you have given is bad. Your rent receipt will prove the nature of the tenancy, and if you have any real doubt on the matter send us the receipt for rent due September 20th last or October 14th, and any other receipts you may have preserved.—K. C. T.]

Notice to determine weekly tenancy.—D rents a garden and factory at a weekly rental of 1s, paid weekly, both adjoining each other. D has sub-let the garden to B at a yearly rental of 12s, paid yearly. D has since died, but factory is still carried on as usual by D's family. The landlord desires that B should have notice to quit the garden. What notice should be given? No written agreement ever existed on either side.—G. H. G.

[As between D's executors and B, the latter is entitled to half a year's notice to quit, expiring at the same time of the year as the tenancy

VEGETABLES.

HARDINESS OF BROCCOLI.

It is very questionable whether any variety of Broccoli in cultivation is fully entitled to the prefix "hardy." Some are certainly more to be relied upon than others, Model, perhaps, being the hardiest of all, although this season I have a fair proportion of the smallest plants left of both Leamington and Lelsham's Latest of All. There cannot be any question that in far too many instances too much space is given up to such a chance crop as Broccoli undoubtedly is. Some gardens are ill-adapted for the successful growth of Broccoli at the best of times, being very low-lying, also closely walled in, and very likely surrounded with tall trees. Under such circumstances the plants do not make that sturdy growth seen in more exposed gardens where a free circulation of air is assured. The cultivator is sometimes to blame, as, besides sowing the seeds much too early, the seedlings are so crowded in the seed-beds that good plants are an impossibility. Large plants are not by any means the best to stand the winter, for unless the weather should be very favourable for them they will most surely succumb. A small head of Broccoli is much better than none at all; therefore, if the plants may appear small upon the approach of autumn, the grower need not envy those who may have much larger plants.

By sowing the seed about the first week in May, in rows instead of crowding up the plants in a small seed-bed, good plants may be secured, capable, at least, of withstanding more frost than weakly and drawn plants. I could never see the wisdom of sowing on very poor ground, as some advocate, for if so, and a dry time should set in, the growth is so slow that it is with difficulty the fly can be prevented from devouring the young seedlings. By sowing on fairly fertile ground, taking that ample room is allowed the young plants and also that the site is well exposed, the plants will not grow any too freely. It is just the same at the final planting, for if plenty of room is not allowed, the plants fail more or less just the same. Too much care cannot be taken in the selection of varieties, and in recommending any kind a hard-and-fast line should not be drawn. A.

CULTIVATING ARTICHOKE.

The true Artichoke is a very valuable plant, much more used abroad than with us, a great many being brought now to our markets. In our mild winters in the south it very often escapes as in France, if protected by leaves or some such material; but in our gardens, where the cultivation of this vegetable is not so systematic as it is abroad, the heads are not so fine as they should be, because the plants are not relieved of their suckers, and the consequence of this is that the growth is so rapid and dense that the fruit is reduced in size. To obtain good Artichokes, therefore, it is necessary to remove the suckers when the plants

begin to spread. It is hardly necessary to say that the Artichoke referred to here is the true Artichoke, what we call the Lepusdem Artichoke not being an Artichoke at all. Those who have cultivated Artichokes for any length of time know that exceptional cold is not the only danger to the growth of this vegetable, as the parts under ground are really more liable to suffer from stagnant moisture than from frost, however severe. When the surface is properly protected by straw, manure, or leaves, it will not be surprising if, after copious and continuous rain, in spite of the precautions against frost, a great many rhizomes are found to have perished, especially in badly drained soils. It rarely happens, however, that in a plantation of any size the plants all perish. The worst used plant will produce useful suckers, though doubtless plants which have come well through the winter will have the advantage in this respect also. Here we may, perhaps, recall the fact that Artichokes are perennials which occupy the ground where they are planted for four or five years, and each rhizome produces a greater or less number of suckers, according to kind, the majority of which should be cut away, when large enough, at the base, after removing the soil for that purpose. The time for removing superfluous suckers is the second half of April or a little earlier or later, according to the state of the weather, and the instrument to be used is a flat dibble or a long knife. Every part of the sucker is removed, together with a small portion of the heel, the most promising-looking suckers being left, and as much as possible kept in line with the rest of the plants. More mutilation of the rhizomes than can be helped should be avoided, and in each case the incision should not go beyond the diameter of the base. As fast as the suckers are removed they are classified according to strength, as they can be used for making new plantations, the preference being given to those of medium thickness and with some roots attached to them. Stout suckers, thick at the base and with leaves broadening from the point of attachment, should be rejected, as they root badly, but the small suckers can be used if need be. Ordinarily in planting suckers the dibble is used, and two suckers are planted together, so that one can be removed when they have taken root. With a limited number of suckers, however, it may be necessary to plant singly, and then more care should be taken to see to the rooting. Also avoid unnecessary watering during the rooting process, or the chances are the plants will rot. One good watering at the time of planting, followed by another if the soil is really parched, should suffice. When the plants are all rooted, however, they can do with large quantities of water. Artichokes should, as a rule, be planted about 3 feet apart.

J. FOUSSAT (Revue Horticole).

NOTES AND REPLIES.

Handsworth Borecole.—Among several varieties of the winter Borecoles or Kales I have grown this season, none has proved so good as this, both for hardiness and quality. The growth is somewhat tall, and the heads

which are almost as solid as a late Savoy, are curled like, or similar to, the Scotch Curled, and are excellent from every other point of view. Those, then, desirous of a change of variety for the next winter's use should obtain this from a reliable source. Not only is it good for winter, but the heads remain solid until well into April before showing any sign of running. Its hardiness is beyond question; scarcely a leaf would appear to have been injured by the past severe weather. As the present is a good time for sowing, readers would do well to procure seed at once. W. S.

Wire hurdles for Peas. Except in wooded districts the purchasing of Pea-sticks is often a serious item in the garden expenditure. To obviate this difficulty, of late years galvanised Pea hurdles have been introduced. I do not look upon these wire Pea hurdles with particular favour; I much prefer the old-fashioned sticks. The advantage of these wire hurdles comes in where Pea-sticks are with difficulty procurable, and although at the outset the cost may appear excessive, yet in the end they will be much cheaper than sticks, as they will last with care for years. But even with the use of hurdles a few small sticks are needed to guide the young growing Peas. However suitable the hurdles may be for keeping the haulm erect, yet it will not intertwine in the wires, as many people suppose. Nor is a single row of hurdles along one side of the Peas of any use; there must be a row on each side arranged about a foot apart. This will keep the haulm erect. The hurdles being made in three heights, 4 feet, 5 feet, and 6 feet, care must be taken that they are used as high as the Peas are supposed to grow.—Y.

A steamy hot-bed.—I made up a hot-bed in the middle of March. I turned it several times; it was fresh, but very wet. I sowed some Cucumbers in heat, which have come up and are breaking into rough leaf. I cannot keep them longer where they are. The hot-bed steams very much, although I have left the back open to let it escape. Kindly tell me what to do, and when it will be safe for the Cucumbers?—X. Y. Z.

[You appear to have made up the hot-bed too far in advance, and we fear by the time you most require the heat it will be greatly diminished. The steam is the natural outcome of the heat and the enclosed frame, and a little steam will do no harm if it is not too rank. All steam may be modified, however, by a thin covering of soil or even light manure over the bed, and by placing the mound of soil for the Cucumbers, this will be getting warm for the plants. You will need proceed cautiously while the cold, biting winds and nightly frosts are with us. At such times a thick night covering must be given, and such assistance may be given from lying the frame around with more hot-bed material. Another time when you have completed the bed, we suggest you cover the surface inside the frame with soil at once. This is a far more satisfactory way of dealing with it than by opening the back, which permits not only steam but heat to escape. In the making up of a dung-bed you should obtain quite one-third of fresh droppings, as these retain the heat far more uniformly than the straw portion. We do not object to the manure being wet, if well turned over several times; indeed, we take care that any dry

portion is not permitted to enter into the bed. Any interval dryness quickly turns mouldy, and where this is the case the heat quickly fails.]

Careful gathering of Spinach, etc., in winter.—For several years I have been noticing how much better winter Spinach

The hybrid Heath (*Erica hybrida*).

stands when some thought and care are exercised in the gathering, especially through the autumn and early winter. I have found it much better to pick the leaves close to the crown, taking all the largest leaves first. In this way there are no stems to engender damp and rot round the plant, and the air hardens the crowns. Added to this there is economy in so doing, as all the foot stems are as good as the leaves. Another mistake is allowing Spinach to remain too thick for winter. I pull up the largest plants and use them the first part of the winter. It is very weakening to pick off every leaf, especially the very young ones. I like to leave enough to help shelter the crowns, and I never commence gathering till early in the autumn, and seldom am I short, except in severe frost. Parsley needs the same care; if the large leaves are left they only get ruptured in the stems and die.—J. CAWOK.

Vegetable Marrows on leaf heaps.

—I grow the Vegetable Marrows on the top of a heap of freshly-gathered leaves, which are stacked in a corner having a southern aspect, and bounded on the north and east by a wall a few feet higher than the leaves. On the top of the leaves I make up a bed with the trimmings from the roadside. A moderate warmth is generated by the leaves, rendering the soil genial to the roots of the Marrows. The plants are now in 4½-inch pots. They will shortly be planted out under handlights and have protection nightly, thus giving an early crop of Marrows. After the crop has been produced the soil is in good condition for using the other ingredients for the cultivation of Vicia.

TREES AND SHRUBS.

HARDY HEATHS.

WHERE, as in many country places, our native Heaths abound, there is little need to cultivate them, but certain of their varieties are charming and deserve a place in the garden or wild garden. In a place large enough for a bold Heath garden it would be well to have it, but a small garden is often large enough for a few beds of hardy Heaths. A Heath garden need not be a rocky or pretentious affair, but quite simple, for Heaths do well on level ground. Though they grow best, perhaps, in peat bogs and wastes, it would be a mistake to suppose that only such soils can grow Heaths well, because we see them in Sussex in soils quite unlike those on which they thrive in Hampshire. If rocky banks or large rock gardens already exist, Heaths may form often their very best adornment, but such are by no means necessary. This group of plants has as yet had but scant care, and, if grown at all, is grown in a poor way, and more for its "botanical interest" than from any just sense of its great beauty. That can only be fairly judged of by those who see them on mountains and moors, where they are among the most beautiful of plants in effect in broad masses. This can hardly ever be shown in small gardens, but why should it not be in large ones? It is by no means necessary to have a garden to cultivate Heaths in a bold and picturesque way, as almost any rough open ground will do, and some kinds will do among hushes and in woody places. The larger Heaths, where grown, should be massed in visible groups, and the dwarf ones seen in dwarf masses also, and not treated as mere "specks" on rockeries, or used as edging plants only.

TREE HEATH (*E. arborea*).—A tall and graceful shrub of Southern Europe, N. Africa, and Madeira; white-flowered, and covering vast areas in the upland woods of Oak or other trees, attaining a height of 12 feet or more in N. Africa, and in the Canaries becoming a tree. This Heath is tender in Britain generally, but may be grown in southern and warm districts and on warm soil in sheltered valleys near the sea with its friendly warmth.

flowering in spring in Britain. The flowers are rosy-purple and fragrant. It deserves a trial in heathy soils and sheltered places and near the coast.

ALPINE FOREST HEATH (*E. carnea*).—A jewel among mountain Heaths and hardy as the rock Lichen. In very mild winters it flowers in January in the south, and in all districts is in bloom at the dawn of spring—deep rosy flowers, carpeting the ground, the leaves and all good in colour. There are one or two varieties all fine in colour, and there is a white variety. This Heath is not averse to loamy soils and does well on some of them. It is easily increased by division. (Syn. *E. herbacea*.)

GREY HEATH (*E. cinerea*).—A dwarf and pretty Heath common in many parts of Britain, and particularly Scotland, is also very easily grown, and has pretty varieties of white and various colours. Its flowers of reddish-purple begin to expand early in June. Amongst its varieties are *alba*, *atropurpurea*, *bicolor*, *coccinea*, *pallida*, *purpurea*, *rosea*, and *spicata*.

THE DORSET HEATH (*E. ciliaris*). is a lovely dwarf Heath, too little grown, and certainly as pretty as any Heath of Britain or of Europe. A native of Western France and Spain, it also comes into Southern England, and we find it hardly much further north than the district it inhabits naturally. The flowers are of a rich purple-crimson, and fade away to a pretty brown. It is neat in habit and excellent in every way, thriving also in loamy as well as in peaty soils.

HYBRID HEATH (*E. hybrida*).—Generally we include varieties under the species, but this, which is said to be a cross between *E. carnea* and *E. mediterranea*, is a remarkable plant, and last season it flowered right through the winter and far into the spring. The Hybrid Heath thrives in loamy soil almost as well as in peat, and like the dwarf Alpine Heath (*E. carnea*), is quite easily increased by division. There is at the present time a fine mass in bloom in the Royal Gardens, Kew.

SPANISH HEATH (*E. codonodes*).—This is the Britain the most precious of the taller Heaths, growing 2 feet to 4 feet high, and being hardier than the Tree Heath (*E. arborea*), it may be grown over a larger area. Even in cool districts we have had it in a loamy soil ten years, and almost every year it bears lovely wreaths of flowers in midwinter, white flowers with a little touch of pink, in fine long Fox-brush-like shoots. In about one year in five it is cut down by frost, but usually recovers.

MEDITERRANEAN HEATH (*E. mediterranea*).—A very graceful bushy kind, growing 3 feet to 5 feet high, best in peat, and flowering often very prettily in the spring. Although a native of Southern Europe, it also comes into Ireland and in the western parts, and is a little more hardy in our country generally than the Tree Heath of Southern Europe—is, in fact, hardy in

The Alpine Forest Heath (*E. carnea*). From a photograph sent by Mrs. G. F. Phillips, Wulverie, Olen.

SOUTHERN HEATH (*E. australis*).—A pretty bush Heath of the sandy hills and wastes of Northern England. Of this species there are several varieties. **THE STRICK HEATH (*E. stricta*).**—A wiry-looking shrub, compact

in habit, about 4 feet high, flowers later, and is a handsome plant. A native of the mountains of Corsica, flowering in summer.

BROOM HEATH (*E. scoparia*).—A tall and wiry-looking Heath, reaching 8 feet or more, flowering in summer, not showy. We have seen this in cold parts of France (Sologne) as well as more abundantly in the west and

30 inches high, bearing crimson-purple blooms in drooping racemes. There is a white variety even more beautiful, and one with purple and white flowers, called bicolor. (*Syn.*, *Menziesia polifolia*.)

Maw's Heath (*E. Maweana*).—This is one of the handsomest of all the Hardy Heaths discovered by Mr. George Maw in Portugal in 1872. It may be best described as a very vigorous-growing variety of *Erica ciliaris*, which it closely resembles, but it is more robust in all its parts; the flowers also, besides being larger than those of *E. ciliaris*, are darker red in colour. It flowers from July to December.

Viburnum plicatum forced.—The Gumbler Rose is now largely used for forcing into bloom, at which time the globular masses of pure white blossoms are very distinct from anything else so treated; but a second species, the Japanese *Viburnum plicatum*, is also equally suitable for the purpose. True, neither of them must be hard forced, but in little more than an ordinary greenhouse they will be in flower by this time, while the Japanese species arrests the greater share of attention by reason of its being far more uncommon than the other. *V. plicatum* is characterised by a spreading habit of growth, deep green wrinkled leaves, and by the profusion in which the balls of creamy-white flowers are borne. It is one of the most beautiful of our outdoor shrubs, as well as a desirable plant for flowering under glass.

Forsythia suspensa. What a mistake is it to hard prune this beautiful shrub, as I feel is done in some places, where the only possible ideal of the gardener in relation to shrub form is that all shall be hard clipped or pruned. If, instead of so treating this free-growing shrub, several of the stoutest of the main stems be tied up loosely to stout poles, then these allowed to branch out freely the following year, they produce wonderfully attractive and beautiful plants in the following spring. I have seen some such this season that have been perfect pictures. In other cases, too, plants trained and nailed loosely to a wall have been allowed to send out plenty of breast-shoots, which the following year have flowered gloriously. But to have these plants, which are such free growers, in moderate control pruning should be done as soon as the bloom is over. Then long shoots are sent out which ripen that season and bloom beautifully the following spring. —A. D.

Ivies. In the summer, when flowers and flowering creepers and climbers are much in evidence, we are apt to disregard the charms of Ivies, but when gardens are shorn of their beauty, and walls are for the most part bare, it is then that they arrest one's attention. I sometimes wonder why so many walls are bare, especially those having a north and north-east aspect. Surely of all wall "furnishers" for cold positions we have nothing better than Ivies? All through the snow and sleet of the past winter I have been struck with the cheerfulness of a wall over which the golden-leaved variety *spectabilis aurea* has run. Ivies give little trouble beyond a periodical mending up, and an annual cutting away of old foliage to make way for new, and one could not choose a more convenient time for planting than now. Here are a few varieties: *Silver Queen*, silver-edged; *Queen of the Alps*, mottled gully; *Don-rail-rose*, green, bronzed in winter; *maudslayi major*, marbled white; *obovata*, large deep green foliage; *argentea elegans*, green foliage, edged white. Grown in pots for the most part I have found that when carefully removed Ivies shift as well in April as at any other time of the year. For covering shaly walls and fences few things are better. —W. E.

Photographs of Gardens, Plants, or Trees. We offer each week a copy of the latest edition of the "English Flower Garden" for the best photograph of a garden or any of its contents, indoors or outdoors, sent to us in any one week. Second prize, Half a Guinea.

The Prize Winners this week are: 1, Mr. G. L. Wilkins, Westbere Rectory, Canterbury, for White Heart Cherry tree; 2, Mr. John Cannon, The Rectory, Parracombe, Devon, for New Zealand Flax.

GARDEN PESTS AND FRIENDS.

MILDEW ON ROSES UNDER GLASS.

This will not attack a thoroughly healthy plant. However luxuriant and clean the foliage may have been previous to an attack, you may safely take it that the plants have received some slight check or other, and thus been rendered more susceptible to attack, and consequently to a rapid spread of the disease as well. This in itself is sufficient reason why suitable remedies should be instantly applied. There are few more insidious diseases than mildew.

There are several remedies. Of course, everyone recommends the one he has found the most effectual and safe. For my own part, I prefer to use an insecticide which will also kill insects and keep the foliage clean and healthy. Now, if due care be taken in the ventilation, temperature, and watering, one composition will be sufficient for almost all insect pests as well as mildew. But the thing of primary importance is to commence early. I make a practice of using the remedy at half strength before any insects or mildew appear. I am convinced this is the more correct treatment, because you not only keep the foliage clean and free from dust, but the early use of a weak solution makes it almost impossible for the enemy to get a footing. To use the various insecticides at the advertised strength, and to do this so frequently as is necessary if you are to keep the foliage clean and healthy, not only comes very expensive, but is really injurious to the plants. Roses require frequent syringing

Maw's Heath (*E. Maweana*).

south. It is hardier than most of the larger Heaths. It is often naked at the bottom and very bushy and close at the top.

BELL HEATHER (*E. tetradix*).—This very beautiful Heath is frequent throughout the northern as well as western regions. It is easily cultivated, and being rather dwarfer than most others, requires rather more open situations; it also thrives in moist or boggy places. This Heath has several varieties, differing in colour mainly. *E. Mackintoshii* (Mackintosh's Heath) is thought to be a variety of the Bell Heather. There is also a supposed hybrid between this and the Dorset Heath. *E. Watsoni* is a hybrid between the Bell Heather and Dorset Heath.

CORNISH HEATH (*E. vagans*) is a vigorous bush worth growing as a low covert plant, thriving in almost any soil, and growing quickly to a height of 3 feet or 4 feet. A native of Southern Britain and Ireland, and better fitted for bold groups in the pleasure ground or covert than the garden. There are several varieties, but they do not differ much from the wild plant, and there is a white form, rather dwarfer. (*Syn.*, *E. multiflora*.)

HEATHER (*E. vulgaris*).—As precious as any kind are the common Heather and its many varieties, none of them prettier than the common form, but worth having, excluding only the very dwarf and monstrous ones, which are useless, except in the rock garden, and of not much use there. Heathers are excellent for forming low covert, and of all the plants, none so quickly clothes a bare slope of shaly or rubbishy soil, not taking any notice of the hottest summer in such situations. Among the best varieties are *alba*, *Alportii*, *coccinea*, *decumbens*, *dumosa flore pleno*, *Hammoudii*, *junilla*, *pygmaea*, *rigida*, *Searlei*, and *laminata*. (*Syn.*, *Calluna*.)

IRISH HEATH (*E. Daleocci*).—The name of this fine plant has been so often changed by botanists that it is difficult to find it by name in books, and we give it by the Linnean name here. It is a beautiful shrub 18 inches to

The Irish Heath (*E. (syn.) Menziesia polifolia* Dabocci).

if they are to be kept clean, and although it is well to use clear soft water only, I much prefer to have it slightly impregnated with an insecticide. Sulphur is one of the most important ingredients when checking and killing mildew. But here, too, a much smaller quantity than is generally used, and applied a little more often, would have a better effect. Some

insecticides contain much more sulphur than others, and this must be taken into consideration when making any solution, especially for mildew. The minutest part of fresh sulphur will kill the mildew if it comes into contact with, and to apply it so profusely as I have often seen makes the remedy very nearly as bad as the disease. I would never advise that it be dusted over the foliage, as it is impossible to distribute it so uniformly by this means as if it were incorporated in the syringing mixture. In the latter case it comes into contact with the whole foliage both above and below, also with the young wood, which is usually affected as well as the leaves. I have frequently seen it advised to cut off all affected portions of growth and foliage. The disease spreads so quickly that, unless it starts from a draught through a hole or broken square of glass, and its presence is noticed immediately, I do not attach much importance to cutting away the diseased portions. When I notice any signs of mildew upon my plants I always add a little paraffin oil to the solution, and, if it does not already contain what I consider sufficient sulphur, more is added. The following are good proportions: To the usual syringing solution I put a tablespoonful of oil to three gallons, and a small teaspoonful of sulphur to the same amount. Keep the whole thoroughly stirred during application, and you will find it effectual. Mildew cripples the young foliage and growth more quickly than any other Rose blight, causing it to blister and curl. E.

NOTES AND REPLIES.

Insects on fruit-trees.—I shall be much obliged if you will tell me in GARDENING ILLUSTRATED what the insects are that I send in a bottle? I find a great number of them in the garden, on fruit-trees, and on the walls, also plants. Are they the real "red-spider"? What remedy do you suggest to get rid of them if they are destructive?—MAY DAVOS.

[The insects you sent in the bottle, which arrived quite safely, are specimens of one of the mites, which, as far as I know, have no English name. Their scientific one is *Trombidium holosericeum*. They are not "red-spiders," and are in no way harmful in gardens, but rather beneficial, as they are entirely carnivorous, feeding on small insects, etc.—G. S. S.]

Plague of ants (E. Welland).—Where you can get at the nests of the ants the best and easiest way of killing the insects is to open the nests somewhat with a spade after the ants have retired for the night, and then flood it well with boiling water, which will immediately kill any insect that it comes into contact with. In a greenhouse, if the nest is made under the paving or in some other position that it is impossible to treat in this manner, it may be useful to make a cup of clay with a hole at the bottom, and, having placed it over the entrance of nest and worked the clay well on to the surface of the floor, to then fill it with paraffin-oil or diluted carbolic acid. When the contents of the cup have soaked into the nest fill it up again. The ants may be trapped with pieces of sponge soaked with treacle, bones which have still a small amount of meat on them, or saucers of treacle, or sugar and beer. The sponges and bones should have pieces of string tied to them so that they may be easily lifted and dipped into boiling water.

The St. Mark's-fly.—In the enclosed box are a number of small brown grubs, which have destroyed my Carnations. I found some of the stems full of them and all the roots destroyed. I have tried lime, but to no purpose. Please give remedy. There are also two white worms in the box and a big fat creature. What are they and what mischief do they do?—CONSTANT READER.

[The brown grubs you forwarded are those of a fly, one of the species belonging to the genus *Bibio*, and probably of *B. Marci* (the St. Mark's-fly), which generally makes its appearance about St. Mark's Day (April 25). The flies are burghish, but with slender bodies, black and very hairy. They do not fly at all well, and may frequently be found in couples settling on leaves. They should be destroyed whenever an opportunity occurs. I cannot recommend any method of destroying the grubs but picking them out of the soil, as it would be dangerous to the plants to use an insecticide which would be strong enough to kill them. The white worms are also the grubs of a fly belonging to the genus *Thereva*. I am afraid it has not any English name. I do not think you need fear

that they will harm your plants in any way, as they are supposed to live on decaying vegetable matter. The "big, fat creature" is the caterpillar of the common yellow underwing moth. These caterpillars are very destructive to the roots of many plants, and should always be destroyed when met with. They hide under rubbish, stones, clods, etc., or in cracks in the soil near the plants, and, if searched for, may often be found in such places. Watering with insecticides is of little or no use.—G. S. S.]

FRUIT.

VINES IN UNHEATED GREENHOUSE.

In an unheated greenhouse, how should the ventilation and atmosphere be regulated for Vines only? Thanks to your directions I can manage the pruning, but know nothing whatever about keeping the house dry or damp, warm or cool. (The Vine is now beginning to go along the roof, and another is just planted, both Black Hamburgh. By giving a little further instruction in your paper (which is my complete guide) you will greatly oblige me.—E. A. S.)

[Though in itself simple enough, it is not easy in a few lines to give advice to the inexperienced reader on the ventilating and atmospheric treatment of Vines in a cold-house. Ventilation should, however, always be given in the morning before the sun actually shines on the roof, both for the safety of the Vines, and with a view to preventing an overheated temperature during the day. Close the house in the afternoon just as the sun is passing off the roof. You do not say what the aspect of the house is, or if it is a lean-to or a span-roof. If the house faces south it may be closed about 3.30 p.m., and opened not later than 8 a.m. In sunless and cold weather give no air, and keep the inside of the house as dry as possible. It is only in warm summer weather you will need to damp the floors with a view to giving off vapour. It is then that a moisture-laden atmosphere is beneficial—the same treatment on cold days would be injurious and probably cause mildew to attack the Vines. Ventilate the house by degrees, increasing the air as the day advances and the sun gains power. Vines in cool-houses do not need to be syringed at any time. When the Grapes commence to colour a little ventilation, afforded both from the side and roof ventilators, is best given at night as well as the day, reducing it somewhat at night, and increasing it again in the morning when the weather is dry. Even when there is rain, a slight amount of air may be left on, as this prevents condensation of moisture on the berries to some degree. We presume that you learn from your GARDENING ILLUSTRATED that dis-budding will be one point needing attention in the removal of superfluous shoots when they have grown about 2 inches in length. To every lateral that has been pruned allow one—the strongest—shoot, and one only, from the joints of young unpruned rods. You will need to tie these down carefully, and, until they are almost touching the glass, leave them to grow upright. When they have advanced two leaves beyond the bunches pinch out the point of each except that of the leader. Do not forget, too, that the bunches will need to be thinned both in point of numbers and the bunches themselves. All very small berries must be cut off, and the larger ones reduced according to the condition of the bunch. Give water to the roots not less than once a month in bright weather if your border be an inside one; oftener if the soil is sandy, and the border shallow and well drained.]

DISBUDDING AND THINNING PEACHES.

MANY a fine crop of Peaches and Nectarines has been ruined by the trees being carelessly dis-budded. The operation is often postponed too long, and then the whole of the tree is dis-budded at one time, with the result that it receives a severe check and the fruit falls. Disbudding should be commenced as soon as the fruit is set, and should be done by degrees, commencing at the top of the tree and working downwards, and it should extend over a week or ten days. Sometimes the crop fails through the roots being dry when the tree is in bloom, as some do not like watering the trees then, especially if the weather is dull and cold. The best way is to thoroughly water the border just before the flowers commence to open, and if the

border is shallow or the soil sandy, apply a slight mulch of spent Mushroom-manure or leafy refuse. This will prevent rapid evaporation. The border should be watered again as soon as the fruit is set. Some, and especially amateurs, err in raising the temperature considerably directly the fruit is set. A gradual rise is best, coupled with as much air as the state of the weather will allow. Thinning the fruit should not be commenced till it is seen which are swelling and which are not, and then it should be done cautiously, leaving the final thinning till the fruit is stoned. The stoning period is a critical one, but dropping of the fruit may be prevented by keeping the border moist from summit to base. When stoned Peaches will stand a good deal of heat, provided a corresponding amount of moisture is supplied and the trees well syringed to keep red-spider at bay. Some varieties, notably Hale's Early and Barrington, also the early American kinds, are more liable to cast their fruit than others, therefore they must be treated accordingly.

STEFFAN.

NOTES AND REPLIES.

Four-year-old Apricot (Enquirer).—The fact of your tree being young and vigorous accounts in part for the production of so few blossoms this year. Trees of many kinds, when much disposed to leaf growth, are shy of bearing. The time of year is not that at which you can do anything to check growth. What you should do is to give every encouragement to that of this summer to become well ripened. This you can do by training thinly the principal and extending branches so that they get full sun. Avoid hard pinching or pruning of the summer growth until July and August, for too early pruning sets up a late and continuous lateral growth which cannot possibly become ripe. The cracking of the fruit may be due to an excess of vigour, sodden soil, moisture, either from rain or artificial waterings after a dry period, or it may come from an absence of lime in the soil. The last you can remedy at once either with new or spent lime spread over the surface occupied by the tree roots, and well watered in. Avoid manure of any kind; young and vigorous trees need none of this, as many suppose. Fertility comes the better from moderate growth. Nail in the principal shoots to the wall as they progress in summer, cut out any there is not room to nail in, but leave the lateral or breastwood until the period already named, when no further excitement of buds occurs.

A gross-growing Apricot-tree.—I have an Apricot-tree which makes wood freely, but never shows more than a very few blossoms, and these generally come to perfection. As the tree is getting larger, I should be glad to know if I can do anything to encourage fruit production?—R. W. TAYLER, *Bury St. Edmunds.*

[There is not much you can do now to aid your tree in giving flowers more plentifully. If you have any doubt as to the presence of lime in your soil you would do well to apply some to the surface, extending over several square yards of surrounding soil. This you can lightly point in, and some burnt refuse (garden smother) would be equally good also, given at the same time or a little later. If the soil is in a dry state give water to carry the lime to the roots. Only point up the surface, say an inch deep, so that no root disturbance takes place. Avoid crowding of the summer shoots, and keep them nailed as growth progresses during the season. This conduces to the full maturity of the shoots, without which flowers, although they form, will not develop into fruits. The point to observe with all wall fruits is to so train them that every leaf and branch receive a maximum of sunshine. Do not on any account give manure of any sort while the tree is in a vigorous stage; this would only aggravate the evil. In the winter, possibly a little root-pruning would benefit the tree. In any case, you cannot err in giving lime or old mortar rubbish, which you could spread thickly over the surface. Fresh lime, only sufficient to whiten the soil, should be given.]

The Black Currant mite.—Would you kindly tell me the cause of the swollen buds on enclosed cuttings from Black Currant bushes? I have several in this state, and as others are not so largely affected, I should be glad to know the reason?—F. D.

[Those who have small gardens have few Black Currant bushes, and not infrequently they are planted here and there, other kinds of

currants and Gooseberries intervening, hence there is not that immediate contact bush with bush which is found in market gardens, where the areas are very extensive, the bushes touching each other. In small gardens it is well to exercise some care in examining the Black Currant bushes, as it is now the infested buds are most noticeable. These are more likely to be found low down the shoots than higher up, and if they are burst or partially open it is almost certain they are infested with this pest, which is a tiny mite that can be seen only with a strong glass or microscope. Once a bud is so infested, not only is it practically destroyed, but it is also a centre for breeding and diffusion of the mite. For these reasons it is a wise measure to gather these burst buds and burn them. During a recent discussion it was said that gathering these buds did not stop the development of the insect, but it is absurd to suppose that such gathering does not greatly check the advance of the pest. It is poor comfort to be told that once a breadth of bushes becomes infested there is no other remedy than

the roots of each tree or bush of half-long manure, as that will check evaporation. The more readily these newly-planted things can be induced to root early, the better will they be able to withstand summer heat and drought.

BEAUTY OF FRUIT-TREES IN BLOOM.

Few objects are more beautiful and interesting during the spring and early summer months than our fruit-trees when in bloom, and we see no reason why the fruit-garden should not constitute a necessary portion of the pleasure grounds of every country house. What can be more beautiful than the Apple, the Pear, the Plum, and the Cherry when in full bloom? They are, in fact, interesting objects at all seasons of the year. It rarely happens, however, that they are placed where their beauty can be appreciated and enjoyed. They are too often grown in the kitchen garden, or they may be in some out-of-the-way place known as "the orchard." Why not instead give them a place in the pleasure grounds? Clumps or

be got. However, an Ash-tree was cut down and with difficulty raised to support the old limb. The tree is well worth a visit when in bloom, and I should be glad if some one could tell me what the probable age of this fine specimen might be.

PLANTS AND FLOWERS.

OUTDOOR PLANTS.

SIX TUFTED PANSIES FOR TOWN GARDENS.

(REPLY TO "C. B. D.")

THESE plants are well suited for town gardens, but it is of the highest importance that only those sorts which possess a really good constitution should be selected. You will find the following well adapted for your purpose, and the range of colouring is varied:—

COUNCILLOR W. WATERS is one of the most distinct and valuable sorts, the colour being

White Heart Cherry-tree in bloom. From a photograph sent by the Rev. G. L. Wallace, Westbere Rectory, Canterbury.

destroying them by burning. That it may be difficult to repress the spread of the mite by picking only in a large breadth is probable, but in small gardens it has been done with great success. All who grow Black Currants should examine their bushes, and if they gather infested buds as advised there can be no doubt but that great good will result.]

Newly-planted fruit-trees.—In spite of the occasional showers, all too light, which prevent us, there is just now an almost unwonted lack of moisture in the soil, and grove fears are entertained that unless considerable rains come, or we have a dripping summer, vegetation will suffer very much from drought in July and August. Newly-planted things would, in such case, suffer most, and it will be well if, without waiting for the heat or drought, all these newly-planted trees and bushes have, once a week, so long as there is little rain, a fair soaking of water. Soil is now feeling the warmth of the sun, and, of course, dries all the more rapidly. For that reason, besides the waterings, there should be placed a mulch or dressing about

groups of varied forms and dimensions might be planted here and there, while single standard trees of various sorts might be allowed to assume their natural form, the whole area being traversed by winding walks to allow of the examination and enjoyment of the various fruits. By adopting some system as here suggested, and by arranging the trees so that the fruit-garden could merge into the pleasure-ground, and so, as it were, constitute a necessary portion of the same, and combine the useful with the ornamental, we could give to country houses and small residences an additional interest at all seasons of the year.

The Rev. G. L. Wallace, Westbere Rectory, near Canterbury, who sent us the photograph from which our illustration was prepared, says: "I cannot find out the age of the tree, but the old residents of the village say it was an old tree in their young days. One of the largest limbs has for many years been propped up. Last spring this support, having rotted, gave way, and I was afraid the limb would break off before another support could

a very effective purplish-violet. The plant is free-flowering, the habit dwarf and compact.

MELAMPUS.—There are now many excellent yellow sorts, but for freedom of flowering and also for its spreading habit it would be difficult to find a better. The rayless blossoms are large and of good substance, and the colour may be described as deep rich yellow.

WHITE EMPRESS.—This variety is also known as *Blanche*, and, in consequence, has sometimes misled growers. It is a compact and sturdy plant, with a good constitution. The flowers are large and circular and of good substance, and, like many of the best of the newer sorts, are rayless. The catalogues invariably describe the blooms as pure white, but, as a matter of fact, they are of a pale creamy-white colour.

DECESS OF FIFE.—This will provide a pleasing contrast to the self-coloured varieties, the flowers in this case being margined or edged. The blossoms may be described as somewhat oval in form, the colour being primrose, distinctly edged with blue, and slightly tinted

innive. It is one of the very best representatives of the type of plant, possessing a creeping-like style of growth, and the constitution is all that one could well desire. It is a profuse bloomer.

VIOLINS.—This is one of those beautifully refined rayless sorts of a pale bluish-lilac colour. The plant has a perfect, tufted habit of growth, and flowers freely all through the summer.

SEAGULL.—A variety developing rayless blossoms of the purest white. The individual blooms are large, of good substance, and very rhinate. The plant is very robust, and the cuttings, inserted in the open, have come through last winter without protection of any kind, and are now splendid pieces.

D. B. CRANE.

MAKING NEW GARDEN.

(REPLY TO "SAXON.")

As you propose to have in your new garden—now a meadow—but one foot-path, that should be fully 5 feet wide. As to what may be the cheapest material, much depends on what the cost of getting any locally may be. Thus, in a chalk district it is probable that gravel is scarce; also, it may not be easy to obtain clinkers and binders. Probably, your best way would be to open at one end of the ground a pit from which you could obtain chalk. Then, marking out the path, dig out the soil 6 inches deep, and, putting that to help form a good flower-border or raised borders, till up with chalk, which will ram down firmly. Then, if you could coat that over with an inch or two of small cinders or coarse ashes, you would have a capital dry path. You would do well, having at present plenty of meadow turf, to cut off enough (12 inches wide) to make edgings to the path each side. You could keep those cut with a small lawn-mower, and thus have a nice effect. With respect to ornamental shrubs, plant in give both nice foliage and berries variegated Aucubas at the back, and at every 20 feet a male variety; then intermix red Flowering Currants, yellow-flowered Forsythias, white-flowered Mock Oranges (Philadelphia), Deutzia crenata flore-pleno, white and yellow Broomras, Rhus Cotinus, Weigelas, and Viburnums or Snowball trees. Crataegus Lalundi makes a beautiful object when in full fruit in the autumn. Golden Elder and Samarra, if they be cut back hard each spring, give very fine foliage effects also. If along the borders you can lot in such flowering trees as Laburnum, Pyrus floribunda, Paul's Crimson Thorn, double-blossomed Cherry, and the dark-leaved Prunus pissardi, you will add greatly to the general effect. Fronting these things have good hardy but not tall perennials, and you should soon have beautiful borders.

PLANTS SUITABLE FOR A PEATY BANK.

I HAVE a steep bank facing south, shaded by deciduous trees, from which I cleared a jungle of Brambles, etc., so that it now looks bare. The soil is peaty, covered thickly with leaf-mould. What would be best to plant it with? The rest of the place is thick with Ivy and Bunchells, so I want something different. The Brambles prevented those from covering this bank. Strangely, there are not many wild Primroses. Would they be likely to do it if sowed the seed, or Anemone apennina if I sowed the seed? Would Pionies blossom under such shade, or Anemone japonica? It was in just such a habitat that I saw it wild in the Himalayas. Nothing that is liable to be eaten by rabbits would do. The bank is beside the carriage-drive, so I do not like it to look bare. There are large Rhododendrons here and there.—E. A. B. W.

[There are many plants that might adorn such a bank, but whether all of them would be rabbit-proof we cannot say. On a bank of this kind, however, with peaty soil, you may grow many things, such as hardy Ferns in variety. From your letter you appear to wish for such things as may be grown from seed, and such as Anemone apennina would take two years, and possibly more, to produce flowers. We are not surprised at the absence of Primroses, which in some districts are abundant. They are rarely so where peat abounds. You may, however, plant Periwinkle in variety, London Pride (libbling it in in single rosettes over a large area), St. John's Wort, and the fine carpet afforded by Pyrethrum Tchihatchewi. Anemones and Daffodils would be almost sure to thrive, but it is now late for planting the latter, although you may yet plant tubers if

the Anemone. Snowdrops, Chionodoxa, and hardy Cyclamen are other good things for such a place, and the Caper Spurge (Euphorbia Lathyris) would make quite an effective subject, and is easily grown from seeds. The Butcher's Broom (Ruscus aculeatus) and the dwarf Daphne (D. cneorum) would be also suitable. The Anemone japonica may do quite well if the soil is deep enough, but we would expect the Snowdrop Windflower (A. sylvestris) to do better. Pionies do not object to shade altogether, but to the dryness of root that too frequently follows as a consequence. Unfortunately you do not give the district from which you write, or even the size or extent of the bank, items that would have been of material help. We may say, however, that Megasea cordifolia purpurea is an excellent subject in such a case, and any of the Anemones of the hortensis or coronaria type, all of which are quite easily raised from seeds if kept moist. The common Flag Iris (I. germanica) is a fine plant, and hardly less so than the Pyramidal Pea, in white and rose shades, if planted high and permitted to trail down the bank. Such as these may be planted now, and then by filling in in early autumn any remaining spaces with Fritillaria Melegris, Baffodils in variety, and Anemones, quite a new aspect will be given to the spot. If you specially wish to introduce Primroses, we would suggest a few plants as well as sowing the seed. One item of success with these things is sowing the seed as soon as it ripens. In such cases it vegetates in the autumn ensuing, whereas the same seed may refuse to grow if put away for a time.]

CLEMATIS COCCINEA HYBRIDS.

I BOUGHT two plants this spring of Hinchey of York and Duchess of Albany. They say they are crosses of coccinea, and a large-flowering one. Can you tell me if they really are of a pretty pink colour, and as fine and novel as the catalogues say they are? I have been raising seedlings myself from bought seed, and have some plants which were put out last spring, looking very healthy and sending out strong shoots. They seem to have stood far better winter well. Only one flowered last year, a large pale lavender. I read in a book that to get seed in this country one must fertilise the flowers with a hair pencil. Is this so? Would it be possible to cross montana with a large pale lavender one which flowers about the same time? I have to thank you for your directions about grafting. I had no propagating-pit, but the gardener filled a large flower-pot with stable litter, the same as for Mushrooms, and put the grafts in small pots sunk in it, with a large bell-glass over, and they are looking remarkably well and growing. C. M.

[The Clematis you name as crosses from C. coccinea are certainly novel and good, distinct in form, and equally so in colour. There is more of the bell shape in the flower, something that calls to mind a widely-opened Lappagerin blossom, therefore quite distinct from any other kinds. This drooping and campanulate form, as well as the colour, doubtless reflect the influence of the pretty scarlet species named above. It is worth noticing, however, that the good and worthy kinds were very few indeed, and some hundreds, probably thousands, were raised before anything sufficiently good for retaining was definitely selected. Each year at the Temple Show of the Royal Horticultural Society large specimens of these crossed kinds are shown, and are admired. You will probably find missing seedlings of Clematis most interesting, but the number of good kinds raised from ordinary seed is not large. We have seen huge flowers the diameter of a dinner-plate that could only be called ugly in colour and size. There is no need to fertilise to obtain seeds of the ordinary kinds you possess. The bees will do this far better than you, and, moreover, will not spoil the organs of the flower. But if you wish to obtain success in hybridising—which is another thing—you will need set about it systematically to secure any good results. For example, should you wish to introduce any given colour to another kind, better in constitution it may be, you will require early after the opening of the flower that is fixed upon for the seed-bearing to remove all its anthers, and so put away the possibility of self-fertilisation. Then, when the foreign pollen has been applied to the stigma, the flower should be protected with gauze to prevent any insect carrying other pollen to it, and thereby upsetting all your work. It will also be necessary to insure success that the flower be fertilised three days in succession about midday. Your inquiry about C. montana, whether it is possible to cross this with a

coloured form, can only be decided experimentally. We have not personally attempted this cross, but in view of the C. coccinea crosses already existing, it should be quite possible. In making or attempting it, you would have to forward a coloured kind under glass, and, if you do it, we would suggest C. montana as the seed parent by reason of its free growth, earliness, and hardiness. Some coloured kinds bloom quite well with little forcing, and the flowers should be allowed to expand in quite a cool temperature, and so obtain good and reliable pollen. In these and similarly wide attempts in cross-breeding the best results are only secured in a second generation or even more, and mention the fact that you may not be too readily discouraged.]

NOTES AND REPLIES.

The Night-scented Stock.—If "Sall," who inquires in your paper about above, will write to me, I think that I can give him a plant of the right sort.—(REV.) W. FOX, The Rectory, Stanton-by-Dale, Nottingham.

—If "Sall" will send address to Miss Donnan, L'Amiera, Tintoleague, Co. Cork, he will be able to obtain what he wants. I have had this plant for some years. The seeds never came to perfection, but cuttings grow freely.

Daffodils after blooming.—When my Daffodils are done blooming I propose planting them in the garden to ripen, lifting them in July or so, and re-planting in, say, November. Will this treatment do? Kindly say whether the roots should be cut off when lifted?—No NAME.

[If your Daffodils have already flowered in pots this season, and been forced or brought into bloom in a foreign way, the same bulbs will not give satisfactory blooms next year. It is not merely a question of ripening, but of affording such treatment while the growth is being made that a new flower-bud follows as a result of the same. You say nothing about the variety of which you speak, and there is a great difference in this.]

Growing Eremuri.—I was much interested in the recent article on Eremuri. I, also, have lately started growing Eremuri, but not with such success as "E. R." as my plant has not yet bloomed. I bought mine for a flowering plant. It has been in just the same time as "E. R.'s," but has only thrown up leaves so far. My sister in Devonshire had 12 spikes on her last year. I see GARDENING says the plants should be moved every year. It seems rather risky.—BLANCHE MARY HORSNER.

[No, I should certainly not recommend you to move your Eremuri; they are much better left undisturbed, and should only be moved for two reasons first, if the plants do not thrive and a more suitable situation is found; second, when it is wished to increase them by division, but this, of course, can only be done when each plant has several crowns. You will be able to judge if your plants are in a suitable position by comparing their vigour this year with that of last. If they have increased I think you will not have to wait long for flower-spikes.—E. R.]

Plants for a border facing east.—I have a flower border about 4 feet wide, on the side of a house that faces east, so it only gets the morning sun till about 11 a.m. Will you please say what plants for flowering this year would do best? Would Carnations and Pansies do well?—A CONSTANT READER.

[Yes; both the Carnations and the Pansies should do quite well, and for other things to flower this year we would suggest Tuberosa Begonias, to be planted 2 inches deep at the end of April. These are now obtainable at dry tubers. Then you could plant Asters, Zinnias, and Stocks between the Carnations, the Begonias next, and the Pansies at the front. Some taller plants for the back would be early-flowering Chrysanthemums, with a few such plants as Aster Amellus, A. arvensis, A. leucogonus, etc. The Tufted Pansies would be far more profuse in their flowering than the ordinary Pansies, and last well into the autumn. You will need have the soil deeply dug and manured, and the work may be taken in hand at once.]

Increasing Snowdrops.—Please say if Snowdrops are only increased by division of roots or from seed also, and how and best time to do it.—T. W.

[These plants are both increased by seeds and by division of the clusters of bulbs. The seeds may be gathered as soon as ripe and sown in boxes or pans of light sandy soil in a cool, or if your soil is light, they may be sown in the open garden and lightly raked in. If done this way you will need cover them to keep birds, cats, etc., away, and while you are doing this you may as well sow in boxes and have them under the eye at once. Re-

division may be taken in hand just as soon as you like when the leaves turn yellow. At such time you may pull the clumps apart and replant them at once. Drying is not at all needful, and is not beneficial. Avoid replanting in clusters, and in place thereof dibble the bulbs in with a small dibber, not more than two in a hole, the holes to be 6 inches asunder. In this way a large area is soon covered.]

GALEGA (GOAT'S RUE).

The various members of the Goat's Rue family are bold, easily grown perennials. It is a good plan, every two or three years at least, unless in exceptional cases of great depth of soil, to lift the plants and divide them freely in the month of March or early in April. This season is suggested because of the quick way the young plants take to the soil again, though they are so hardy and enduring that they may be taken in hand at almost any time that is convenient. Old clumps can be pulled asunder quite freely—indeed, increase is better done in

old plants, of which a portion may be left, flowering first, with the young ones as a succession. The genus is by no means an extensive one, and is composed of one or two species and their one or more forms in each case.

G. OFFICINALIS, a native of Southern Europe, has lilac-blue Pea-shaped flowers, and grows from 3 feet to 5 feet high. Of this species there are at least two forms—viz., that known commercially as *G. o. compacta*, which, I believe, is now regarded by botanists as the type species of the genus, and *G. o. alba*, the pure white kind so valuable for cutting. A much improved flowering form of this last would be welcomed. There is also said to be a pure white form of the variety *compacta* called "Snowball." This I do not remember having seen, and am therefore unable to give any opinion of its merits.

G. ORIENTALIS is a Caucasian species, and attains to 6 feet high when fully grown. The flowers are bluish-purple. The somewhat creeping roots and flexuous stems are the chief distinguishing characteristics of this plant.

distinct kind, though disposed to become bleached in the hot weather. The blossoms, too, are rather smaller than in most others. Grown where the clumps can be slightly sheltered from the sun during the heat of the day, excellent results are gained. Colour salmon-orange. In Prince Edward of York the blossoms are large and handsome. The colour of the standards is scarlet with rose wings. *Coccinea* is another new sort which is sure of a good reception. Colour bright scarlet and red.—W. V. T.

Treatment of Auricula.—A year or two ago I had half-a-dozen Auriculas, bright blue, with yellow centre, large flowers on a stout stem. I have now only one little plant left: it is in the open border, and has been there through last winter. Would you advise my putting it in a pot in the autumn in a frame, or letting it remain where it is, only protecting it a little from the wet? Would you kindly give me the name and address of the secretary of the Auricula Society?—It. BROAD.

[We should advise you to lift the Auricula as soon as it has finished flowering, and put it in a frame with a northern aspect. In this way you will possibly be able to save it. The Secretary of the National Auricula Society (Southern section) is Mr. T. E. Howwood, 61, Hamilton-road, Reading, Berks.]

Planting a flower-bed.—I shall be very much obliged if you will give me some advice in an early issue of GARDENING ILLUSTRATED as to the summer planting of a circular flower-bed, about 13 feet in diameter, in an open, sunny position, a good depth of ordinary good garden soil? What I propose to do is to plant the greater part of the bed with *Phlox Drummondii* in various separate colours, arranged in circles, and small triangular patches of French Marigold Silver King. I should be very much obliged, indeed, if you will tell me if this arrangement would be likely to make an attractive bed, and one that would be bright for some months during the summer? Also, what would be a good distance to plant the *Phlox Drummondii* apart to be most effective? I have the plants of the *Phlox* now pricked out under glass, so that they should be quite forward enough by the time for planting out. The *Phlox Drummondii* I have are large-flowered white, deep crimson, yellow, scarlet, height 1 foot; also *Fireball*, height 6 inches.—C. B. W. B.

[It is quite possible to make a gay, effective bed with the *Phlox* and *Marigold*, but hardly in the way you suggest, for this appears to be rather patchy. Why not make a bold centre, say, 6 feet in diameter, or even 4 feet, of the *Marigold*, and then arrange the *Phlox* in distinct blocks of colour around in large oppositely-placed triangles, the wide acute angles being at least 3 feet apart, and better still if 4 feet at the points? In this way you will obtain more effect than by the smaller circular patches you suggest. Not only so, for, seeing the *Phlox* predominates in your case, we think it the better plan. Or you may arrange the four colours as suggested, and margin the bed around with *Fireball*, the dwarf one. This arrangement would give a definite centre, decisive blocks of distinct colours around, and a definite margin to the whole. By planting the white, crimson, yellow, and scarlet sorts thinly, and slightly pegging down at planting time, a more bushy plant will be formed and the height modified somewhat to balance the dwarfier plants in the centre, which, however, will be assisted by occupying the higher portion of the bed. This, we think, will give you more effect than a far greater number of smaller patches that lose by their insignificant size.]

Pansies.—Some people who grow Pansies prefer to buy the plants, often when in bloom, to know actually what they are getting, instead of raising their own plants from seed. It is, perhaps, more trouble to sow, prick out, and wait results, but, if seed is purchased from a trustworthy source, I always think there is a certain amount of pleasure attached to seed raising, whether Pansies or Carnations, or whatever one takes in hand. There is very little trouble about Pansies; the seed is sown in a box or bed made up in a frame, many of which will presently be empty, and from six to eight weeks from the time the seed is put in the plants begin to bloom; or supposing one has no frame, there is always the open border, and seed sown there at once will, I venture to say, furnish blooming plants by July. Good seed will provide plants of good quality, coming in very useful either grown in beds by themselves for second row plants in the borders, or for filling up any spaces that may have occurred through severe weather, etc. The question of expense is not a little one in many gardens where almost everything has to be bought, and therefore, send this here, as to the sowing of Pansies now, as they make a show very soon,

The white Goat's Rue (*Galega officinalis alba*). From a photograph by G. A. Chumpton.

this way than attempting division with knife or spade in such frequently cross-rooted subjects as these. Each old flower-stem of the last year will come away, and with root-fibres in sufficient quantity to make it a good plant in quite a short time. Plant half-a-dozen or more of these small pieces at a slight distance apart over say an area of 2½ feet or 3 feet, and a good specimen will be secured in the year of planting. All the kinds may be raised from seeds quite freely, while division is the only way with any good or well-marked form. As cut flowers these plants have a singular beauty of their own by reason of the way the pinnate leaves are arranged behind the sprays of blossoms. So perfectly are these arranged that no addition whatever is needed, and a small spray of any one of the varieties is always presentable even among the choicest of flowers. In this way the white kind, *G. officinalis alba*, is excellent, and as a border plant for effect, or a useful plant for cut flowers, whether in large or small sprays, it should be absent from no torbaaceous border. The habit is elegant and compact. By spring replanting a longer season of flowering is secured, the

G. BILOBA.—In this the flowers are lilac-blue. Height 3 feet to 4 feet. It is doubtful if this interesting plant is in cultivation at the present time. E. J.

Sweet Peas—richly-coloured sorts (*Lathyrus odoratus*).—There is now a goodly list of highly-coloured Sweet Peas, and as blossoms of the warmer shades of colour are much more effective under artificial light, we can understand your preference for the crimson, salmon, and other kindred tints. The subjoined list should meet your requirements: *Lady Mary Currie* is a distinct and very fragrant flower. The colour is described as orange-pink shaded with rosy-lilac. *Salopian* is another fine Sweet Pea, the colour in this instance being deep crimson suffused orange-scarlet. In Mars not only are the flowers very large and handsome, but they are freely produced on a long and stout flower-stem. The erect standards make this a most valuable flower. The colour is bright fiery crimson. *Miss Willmot* is one of the newer Sweet Peas, the lovely salmon-red flowers large and handsome. *Gorgeous* is a very

and are, moreover, nice for cutting for small pots, vases, etc., for the table. Pansies require little in the way of soil, sharp sand, or road-scrappings, mixed with the soil in the borders, answering well, and given a sunny position they will bloom long and well, and warrant any trouble that may be bestowed now.—W. F. D.

INDOOR PLANTS

THYRSACANTHUS RUTILANS.

For decoration, even when kept exclusively in the stove, plants of this *Thyrsacanthus* when in flower are a great boon. Many who have grown it have not developed its beauties to the greatest possible extent, this arising no doubt from a lack of knowledge as to its adaptability. Too often the plants are struck yearly, whereas it is best to grow on the plants and burn them into standards of 3 feet or so in height. I have grown them myself to a height of 5 feet as standards, this height affording the opportunity of inclining the heads forward and partially over the pathway when in bloom, whereby a beautiful effect was produced. The quantity of flowers and the number of racemes on these taller and older plants are greatly in excess of what can be possibly had on the younger ones. Standards of this description will last for several years; thus propagation only need be done to keep up the desired quantity. When out of flower these older plants will do with a rest, being partially dried off and stood in an intermediate house. Growth should be started again in this cooler house when with the spring warmer weather sets in. In no case is it necessary to keep the plants in the stove to make their growth, even in the culture of young plants when once well established. During the summer a light, airy house will suit them well, the chief point to observe being the building up and solidifying of an enduring growth. In favoured localities *Thyrsacanthus rutilans* may be grown out-of-doors from June to September, thus saving room inside, the results being all that one could wish. The ordinary soil for stove plants (peat and loam) will suit it well. *T. Schomburgkianus* has darker flowers than *T. rutilans* and is often confused with it.

HYDRANGEA THOMAS HOGG.

From the middle of March onwards *Hydrangea* are valuable as flowering plants for the greenhouse and conservatory, especially so Thomas Hogg, the white variety, whether from cuttings inserted during early April, or older plants that have been pruned back after passing out of flower. But it is to

H. THOMAS HOGG I wish to call attention, as cuttings put in at the date mentioned can be had in bloom quite easily by the first week in April if a temperature of about 60 degs. to 65 degs. can be maintained, and the plants kept within 2 feet of the glass roof. To procure cuttings at so early a date it is necessary to grow on an old plant or two, which, if placed in heat early in January, will usually have a few flowerless shoots. These should be taken off at this date with three pairs of leaves attached, cutting them clean across close up to the oldest leaves and inserting them, six in number, around the sides of 4-inch pots that should have been previously filled with sandy loam and leaf-soil, with a dash of sand on the surface to work down with the cutting. Place the pots in a chase case or under a bell-glass in a temperature of 60 degs., with a rise of 10 degs. or 15 degs. with sun heat, keep these chase and shaded from the sun, and lightly dewed overhead whenever dry. In four weeks they should be ready to pot off singly into 3-inch pots, using a similar soil as above. Shade for a day or two if necessary, and then remove to a light position in a Pench-house, and, as soon as the plants begin to grow again, nip out the point at the second joint. This will encourage four, and often six, shoots to throw out, two at the axils of each pair of leaves, and two from the very bottom. As the pots get filled with roots slit into 5-inch or 4½-inch pots, using mostly loam, a little bone-meal, and a dash of sand to keep it open. Pot firmly, and keep under glass until re-established, when place out-of-doors where plenty of sun can reach them, that the growth may be thoroughly ripened

October. At no period of its growth must the plant be neglected in the matter of watering. A stimulant given once a week when the pots are full of roots will assist the plant to build up stout, sturdy growths, which, if properly ripened, cannot fail to form flower heads. Protect from severe frost until early in January, when introduce into heat as before advocated.

H. HORTENSIA may be treated in a similar manner, but this variety will not push up more than two shoots worth retaining for the next spring display. Cuttings may also be put in during July or early August, taken from outdoor plants, and rooted under a worth wall under a hand glass. These should be placed singly in small pots and not be stopped, but allowed to mature the central growth. This, in due course, will carry a fine head of bloom towards May if treated to a little heat early in March. After flowering, cut the plant fairly hard back, keep in a little moist heat, and, when breaking nicely, reduce the ball of soil a bit and repot into two sizes larger, keeping under glass until re-established, when gradually harden and place out in the full sun, as with the younger plants. Under this treatment I have plants of *H. Hortensia* in 8-inch pots carrying eight heads of bloom that were only rooted two years ago, while Thomas Hogg, which is not such a strong grower, has ten or twelve heads in pots 6 inches or 7 inches in diameter.

[With the above note came a plant in a 6-inch pot, carrying six fine heads of bloom, one on the leading shoot and five on shoots that had started from the base and the axils of the leaves. This plant had been struck from a cutting put in in April of last year.—E.]

SHADING PLANT HOUSES.

FREQUENTLY the amount of shading employed is far in excess of what is really needed. When this is the case, it must be apparent to any thoughtful cultivator that the plants thereby suffer rather than derive actual benefit. It would be far better to dispense with shading, as it is generally understood and acted upon, than to allow this excess to continue. Those who have not experimented with light shading are strongly recommended to do so. In shading plant-houses of any kind, all that is actually needed is to scatter or break up, so to speak, the rays of the sun from injuring the plants in the way usually termed scalding. It does not require a thick shade to do this; in fact, it is remarkable what a light shade will accomplish in this way. It frequently happens that the quality of the glass is not by any means what it should be. When it is of inferior quality, with spots in it, it is not fit for glazing any kind of houses. These spots produce lenses in the glass, and these, when focussed upon the foliage, produce injury or burns. I have no doubt that many besides myself have noted that these burns are often in a line. Take, for instance, a Palm leaf that has been thus injured. There will possibly be several scabs or burns in a line with each other. These burns are not caused simultaneously, but proceed one after another in accord with the movement of the earth in its relation with the sun, and all proceed from one and the same spot in the glass. The best mode of procedure in such cases is to trace out, if possible, the spots in the glass and touch them with paint. This will prevent future injury as long as the paint remains in the glass, which will usually be the case for a few years at the least. This is a far better mode to adopt than that of covering with heavy or dense permanent shading, or even of using blinds injudiciously. It is a mistake to imagine that because a few scabs have taken place, therefore shading is absolutely essential to prevent it; nothing of the sort is, in some cases, needed other than that just advised.

Shading with whitening or lime is not only a bad method, but a hideous one, especially where the mixture is daubed on in a haphazard fashion. Lime should never be used, in fact, whitening of the twin being much the better material. When whitening is chosen, it should be mixed with size to make it adhere, 3 lb. of the former to 1 lb. of the latter, with sufficient water to reduce it to about the consistency of paint or a little thinner. The size has, of course, to be dissolved by boiling it in

water. When this is applied it should be put on as thinly as possible and be stippled over with a painter's dusting brush. Mixtures as sold for the same purpose are also good, being easily mixed in water. Of the two colours of these I prefer the white to the green. In dealing with the green shading, there is the danger of using it too heavily, much more so, I think, than the white. In no case, however, would I use either where blinds could be employed. Even upon pits blinds can be used, being rolled horizontally upon small wooden rollers, one on either end. Rough plate glass is, I consider, well worthy of extended use; it may cost more, but in most cases the after expense of blinds would be reduced to a minimum.

DAMPING OFF.

ONE of the things which greatly puzzle amateurs (and, indeed, some professionals) is what is known as "damping off." Young seedlings of all sorts, and some flowers, when grown in-houses, are very liable to damp off, and those in charge sometimes keep an unnaturally dry atmosphere in the hope of checking the evil. Let me assure them that when they do this they are on the wrong tack. Damping off does not occur so much during dull, damp weather, when there is comparatively little variation in the temperature of the house, as it does when there are cold nights and bright days. It is the sudden rise of temperature that does the mischief. If you want to see how damping off takes place, practise the following plan for a few days: Allow your greenhouse to get down to 40 degs. in the early morning, and do not give ventilation till the sun has been shining on it long enough to raise the temperature to 80 degs. When the temperature rises rapidly moisture will condense on all cold surfaces, such as metals, stones, slate, and fruits; and, although it is not always so easily seen, it will also collect on the stems and leaves of plants, and will remain there till such time as the leaves and stems become nearly as warm as the atmosphere in which they are growing. This takes a considerable time. If we take a glass of feet water into a warm dining-room and place it on a white table-cloth, we shall not only see the outside of the glass become wet, but the cloth also upon which it stands will be wet. This is exactly what happens to fruits and plants. Some plants, when their stems become hard and covered with a water-proof bark, are not much harmed when this takes place, but tiny tender seedlings and unrooted cuttings do not like it at all. Were the water in the glass as warm as the room the outside of the glass would remain dry. Having ascertained the cause, the remedy, and what is better still, the means of prevention are obvious. Endeavour to prevent sudden fluctuations of temperature. Do not allow the house to get down too low, and give air as soon as the sun's rays touch the roof. I have known damping off caused by fire-heat in the following way. During a spell of damp, dull weather extra heat has been applied to the greenhouse, with the idea of dispelling damp and causing a buoyant atmosphere. If this was not very carefully done it had just the opposite effect, and caused moisture to condense on the plants in the same way as mentioned above.

WM. TAYLOR.

NOTES AND REPLIES.

Sauromatum guttatum.—In your issue of April 5th a correspondent writes about a "lily" grown without soil or water, which he says he has seen, but does not know the name of. It is "*Sauromatum guttatum*," and is in several catalogues under the heading of "Arum." The bulb will grow and flower without soil or water, and should then be potted, when it will throw up leaves and develop roots. The one I have seen has flowered, and at present has two large leaves, and is growing freely in ordinary soil in a hot-house.—AMATEUR.

Eupatorium lanthimum is a splendid plant for flowering in the greenhouse at this season of the year. It is not difficult to grow and makes a fine bold subject; the leaves, large, deep green in colour, are an effective contrast to the bold heads of soft mauve-coloured flowers. We noticed several specimens in bloom a few days ago, and few things could produce a finer effect. There is great robustness of character in this species, and the wonder is that it is not grown more in all gardens where handsome plants are desired for groups or for

duration, as the flowers remain in beauty over a comparatively long season.

An old Cyclamen corm.—I send you photograph of Cyclamen. I had it in the dining-room from November, 1901, to third week of March, 1902, in flower the whole time. When at its best it had sixty fully-developed flowers of large size and a few buds. The photograph was taken after it had passed its best stage, but was still very beautiful. Apparently it is about a six-year-old bulb, as I have had it three years and it was of fair size when I got it. The flowers are white with crimson centre. —STEPHEN G. WILLIAMS, *Musynooth*.

Planting out Camellias.—I am thinking of building a house for Camellias, 12 feet by 9 feet. What aspect would be best? I should like the plants in middle of house. What is the general way of disposing plants in house? What sized plants should I get, and how many should I want?—D. M.

[When it is remembered to what size a single plant of Camellia will grow, the house you propose to erect is a very small one. We know of plants which must be now over 20 feet in height, and they have borne as many as 2,000 to 3,000 buds. Of course, this size represents many years of growth. It would be well to allow about 5 feet each way for what we may term the permanent plants, and these, of course,

form when plants are about to bloom, and also when they are making new growth. A good size to procure would be plants 3 feet to 4 feet high, but more or less would do. We would rather have bushy plants 2 feet to 3 feet high than tall, leggy ones, for then the most can be made of the space. September is the best month to plant out, but practically any time would do except when the plants are making the new growths. Procure plants that have been propagated in this country.]

Boronia heterophylla.—This has deservedly become within the last few years one of the most popular hard-wooded plants that we have, and no wonder, for it is out difficult to grow, and its beautiful brightly-coloured blossoms are borne in great profusion. The flowers are not so fragrant as those of *B. megastigma*; still, they emit a very pleasing perfume, which must be enjoyed without disturbing the plant, as the leaves if agitated in any way have a heavy, disagreeable smell, which is by no means desirable. The blossoms of this remain fresh and bright for a long time if shaded from the hottest sun, and this is a great point in favour of this *Boronia*. The sober-tinted *B. megastigma* must on no account be passed over, as its little bell-shaped blossoms, delicately poised on slender stems, are so fragrant that a single bloom can for this reason be detected for some little distance. Its scent, too, seems to be admired by nearly everyone, which is not always the case with flowers remarkable for their fragrance. While noticing the above-named species of *Boronia*, the merits of such as *B. serrulata* and *B. elatior* must not be overlooked. The last two flower somewhat later than the others mentioned.

attention I had no difficulty in securing it. Elevated on a platform, with in front of me a table, on which were some fine potting-soil, sharp sand, 5-inch pots, drainage, Moss, and seeds, I first exhibited a pair of pots and asked to be told what they were, next what was the difference between them—one was clean, the other dirty. On that I explained the need for clean pots, the provision of broken crocks for drainage, the proper placing of it in the pots, and its purpose, the adding of a little piece of Moss or other fibrous material. Then, filling the pots up well with the soil, I faced it off and sowed the seed thinly and evenly on it. Thinning out later was advised. Garden soil would not do, but proper pot soil should be got from the florists. Watering, shading, and other attention were also described. —A. DEAN, *Kingsdon*.

ORCHIDS.

MASDEVALLIA TOVARENSIS.

THE flowers of this Orchid, a fine plant of which we figure to-day, are perhaps the purest white of any, yet they have not that dead-looking appearance characteristic of so many white-flowered Orchids. It is in flower during that it is worth growing for cutting alone, besides which the blooms have a very fine appearance on the plant, the white flowers and the green foliage contrasting very prettily. The spikes continue to produce flowers for several seasons, but though it is not worth while on this account to leave all the old ones on, yet it is best not to cut them too close. *M. tovarensis* may be grown with other cool Orchids, provided the winter night temperature does not fall below 50 degs. In a very cool-house the leaves are apt to spot badly. Grown in a cool-house the flowers, if on dwarfier stems, are at least sturdier and endure longer when cut. The amateur may with little heat grow this as well as *Cypripedium* and some *Odontoglossums*, especially the forms of *O. crispum*.

During the growing season and all through the summer and early autumn the plants can hardly be kept too cool. They should be grown in a house well shaded from the rays of the sun, and overhead as well as at-

A useful Orchid, *Masdevallia tovarensis*. From a photograph by Mr. Geo. E. Low, Dublin.

will be planted down the centre of the structure. Other plants could be put out on either side, to be afterwards removed when their room is required for the permanent plants. You could plant out nine to twelve plants at first. The best aspect for a Camellia-house is north to south, and we suppose it will be a span-roof. If possible, have the roof removable, so that in summer you may substitute a canvas roof for the glass—a very necessary precaution with the Camellia—otherwise you must shade the house by having some canvas placed inside near to the roof. When Camellias are grown in pots or tubs it is the usual practice to shade the glass and keep the house close as soon as new growth commences to appear, and the syringe should be freely used morning and afternoon of fine days. Then, when growths are developed, the plants are gradually hardened off and placed outdoors on the shady side of a hedge. This brings the cultivation as near as possible to that in which the Camellia is found growing naturally. In planting out Camellias it is very necessary to provide a good border. Remove the soil to a depth of 3 feet, then put in 6 inches of rough stones or broken bricks, or, if subsoil is very wet, use some drain pipes and connect with a ditch or drain. Camellias prefer an open and porous soil. Two parts sandy loam and one part peat we find the best compost. Add a little charcoal, but no manure. We prefer to give the latter in liquid

form when plants are about to bloom, and also when they are making new growth. A good size to procure would be plants 3 feet to 4 feet high, but more or less would do. We would rather have bushy plants 2 feet to 3 feet high than tall, leggy ones, for then the most can be made of the space. September is the best month to plant out, but practically any time would do except when the plants are making the new growths. Procure plants that have been propagated in this country.]

Children's pet flowers.—A few days since I was invited to choose hardy annual seeds suitable for pot culture for distribution in very small quantities to the children of a school here, the object being to encourage the children by such distribution, and by the offer of small prizes in the summer, to grow these annuals in pots to the best of their ability, and to bring them to a flower service in July. The seeds selected for this purpose were *Candytuft* (white and crimson), *Godetia Lady Albemarle*, *Mignonette Muchet*, *Collinsia bicolor*, *Bartonia aurea*, *Nemophila*, and *Silene pendula*. There were enough seeds in the respective ounces of each kind to enable 400 tiny packets to be made, and these were distributed to 200 children, each one having two diverse packets. But it was felt that some ocular demonstration of the methods of sowing and growing the seeds was desirable, and this much I undertook to furnish. Some 200 bright, attentive children provided a most interesting audience, and for the twenty minutes I required their

atmospheric and root moisture must be very abundant. When the flowers are forming it may be necessary to give a little more warmth, and when fully expanded a drier atmosphere is necessary, or the delicate beauty of the blooms may be spoiled. For compost a thin layer of Sphagnum Moss and peat over good drainage is all that is required. Repotting should take place about once in two or three years, this being often enough if properly done.

Fritillaria imperialis (Crown Imperial) in pots.—I had never seen this growing in pots, and resolved last autumn to try it in this way: My plants, which have not yet finished growing, are rather more than 3 feet high. The bulbs were potted up early last autumn in a compost of loam, leaf-mould, and coarse sand, the loam preponderating. Eight-inch pots were used, and large bulbs were potted up, the crown being covered by a thin layer of soil. The pots were then plunged in ashes and remained there until the end of March. When uncovered, the large and fleshy roots were visible on the surface, and also over the sides of the pots, necessitating some method to preserve them. The plants were, therefore, dropped into 10-inch pots, a quantity of soil being placed on the surface and banked around to form a basin-like receptacle for watering. At this time some 3 inches or 4 inches of growth had developed, and to keep this as

steadily as possible, the plants were placed in a cold and airy greenhouse, the ventilators of which have ever since been open. Within a fortnight a showy and stately plant had developed. In the third week the drooping, bell-like flowers are developing a pleasing orange-yellow colour, and in a few days they will be at their best. In the open air there is a goodly number of plants just now (April 16) at their best. Handsome though these are, and they are really most effective when grouped in half dozens or dozens, I give the palm to plants grown in pots and flowered in a cold-house. This is an advantage to those whose gardens are very exposed, and, in my case, a more bleak and trying position could hardly be found, thus rendering the culture of Crown Imperials somewhat difficult, unless special means are taken to protect the plants from strong winds. When grown in pots, frequent applications of water are needed, and, as the blossoms are in the embryo stage, an occasional dose of weak liquid-manure is very helpful. Their unpleasant odour, which really proceeds from the bulb itself, has probably deterred some from growing these plants, but, from my own experience, this is not so noticeable when they are finishing their growth. This, too, may be minimised by freely ventilating the glass structure in which they are growing.—W. V. T.

ROSES.

ROSES—NEW AND OLD.

It is amusing to read the descriptions of some new Roses, both of home and foreign production. I question whether 5 per cent. will survive the fierce competition to which they will be subjected when compared to old favourites. These new comers look well enough on paper, especially when they have real or fancied pedigrees attached to their names, but rarely do they come up to their descriptions. It is not my desire to depreciate the laudable work of the hybridist. I think roisiers should exercise a little more judgment ere they put on the market varieties not one whit so good as many long since discarded. We now and then receive a real beauty, such as Maman Cochet and its peerless white sport, or the exquisitely coloured Souvenir de William Robinson, which combines all the good qualities that go to the making of a first-rate Rose for the garden, but when it is remembered that some forty or more kinds are annually announced, one marvels what becomes of them. I believe some Continental growers maintain immense collections, but we on this side of the Channel believe in selections rather than collections. It is, however, remarkable what a diversity there is among the almost countless varieties, and comparatively very few are synonymous with other kinds. It has been my lot to grow nearly every Rose introduced to, or produced by, this country for the last twenty-five years. I can recall many lovely gems that have been discarded merely to make room for doubtful improvements. In my opinion the great want of the present day in the Rose world is varieties that are free and continuous blooming, of vigorous growth and perfectly hardy, yet producing all the beautiful tints of the very delicate kinds. And above all things, we want fragrance in our Roses. This is where many of the popular Hybrid Teas fail. I grant that we have sweet perfume in La France, but where is there another Hybrid Tea to equal it in this respect? I am afraid the Victor Verdier race has been too freely used in crossing, for they are notoriously devoid of fragrance. When the sweet-scented Hybrid Perpetuals are employed in cross-fertilising, as in the case of Papa Lambert, a cross between Marie Baumann and White Lady, then we obtain perfume in a liberal degree. I am very glad to find our English raisers are working on the Hybrid Perpetuals more than has been the case during recent years, and I am confident there is much good work to be achieved among this very excellent tribe. I do not know whether we shall ever surpass Charles Lefebvre among dark crimson. It must be a splendid kind to do so. The extremely dark or black Roses need improving. Most of existing kinds have serious defects in one form or another. Of light reds, Alfred Colomb still stands very high in the general esteem. Ulrich Brunner, too, is

good, but I believe one of last season's novelties will surpass it. Of pale pinks, what can be more beautiful than Mrs. John Laing, Mme. G. Luizet, or Mrs. Sharman Crawford? Of deep pinks, Caroline Testout, Prille of Waltham, Helea Keller, and Mrs. W. J. Graat are difficult to surpass. White Roses are not yet perfect. We seem to require a really good globular one, of the Alfred Colomb form, but of snowy whiteness.

Of the extra vigorous Tea Roses the old Gloire de Dijon still remains one of the most popular, and a dozen Teas are rarely set up at a show which do not contain Souvenir d'un Ami and Souvenir d'Elise Vardon, which, forty years ago, were two of our leading Teas.

There is just now a remarkable demand for Rambler Roses, but I observe many desire what we are at present deficient in—that is, good autumnal-flowering kinds of rapid growth and really hardy. Until autumnal Ramblers are obtained growers would do well to plant alternately the few good kinds we already possess, such as Longworth Rambler, Mme. Alfred Carriero, Reine Marie Henriette, etc., with varieties that are only summer-blooming, then the arches, pergolas, etc., will not be entirely devoid of blossom in the late months of the year. Instead of so much extravagant praise for novelties among Ramblers I would remind planters of the many lovely old kinds available, such as Felicite-Perpetue, Flora, Myrianthes renoncule, Aimée Vibert, Blairii No. 2—not forgetting the lovely singles, Rosa moschata, etc., which are so elegant in every way. In conclusion, I may say how interesting it would be to readers of GARDENING if amateurs would write as "M. V. B." did recently concerning Roses that succeed best with them. Many useful lessons could be obtained even by professionals. "M. V. B.'s" description of the Austrian Copper was not at all overdrawn. It is certainly the most lovely colour we have, and how splendidly it grows on its own roots in a light soil. "M. V. B." did not tell us what stock the Roses were budded on, or perhaps they were not budded at all. It always seems to me that the Brier which is used so much for Tea Roses does not adapt itself to every soil, and the success or failure of our own root Roses is more a question of soil than anything else. ROSA.

ROSES WITH HUGE BLOSSOMS.

THERE is no doubt that a magnificent specimen bloom appeals to everyone, and one has only to observe the small crowd that gathers around the flower selected for the medal as the best bloom in the show. Of course, "the best" does not always mean the largest, but, generally speaking, size carries great weight, provided also there be beauty of form and freshness of colour. But if Roses of the type of Mildred Grant increase in numbers, should not there be a special class for them, for it is obviously unfair and also ridiculous to show such Roses with the varieties of ordinary size? The huge Roses are chiefly to be found among the Hybrid Perpetual group. Perhaps the largest variety is Paul Neyron, really a splendid old kind, especially fine in autumn. The two striped sports of this Rose, Panachee de Bordeaux and Coquette Bordelaise, are not quite so large, but they are very prettily blotched and striped with white, the variegation being fairly constant. Another very large Rose is Anna de Diesbach, or Gloire de Paris as it is known in France. The colour is a beautiful shade of carmine, and it is one of the hardiest kinds grown. Her Majesty is magnificent. I shall not soon forget a long row of this grand Rose which I saw at Reigate some years ago. The plants were on the cutting Brier (for it will not do on the Manetti), and every flower was perfect. Many experience some difficulty in growing this Rose or, rather, blooming it. I have found it best to prune very early in February the last season's wood, retaining some 15 inches to 18 inches long, and even up to 2 feet long. This early pruning enables the plant to plump up the buds. Spenser in some respects is a more reliable Rose as far as blooming is concerned, and it is of much the same shade of colour, but the fault of this otherwise grand Rose is the hollow centre. Mme. Eugenie Perle is an Hybrid Perpetual Rose very little

known, but it is a showy kind, quite one of the best garden varieties for the summer. Its colour is bright rose, reverse of petals silvery, growth extra stragg. Boieldieu is another big Rose of fresh cherry colour; so also is Edouard Morren. I think we shall do well not to allow these old Roses to drop out of our collections. They may not be good autumnals, but their massiveness, vigorous growth, and, in most cases, strong perfume, should appeal to all. Mme. Clemence Joigneux is another old Rose, powerfully fragrant, foliage quite free from mildew, perhaps the flowers a bit wanting in brightness, but the lilac-red tint, to me, is rather pleasing if only for variety. The beautiful sport William Warden deserves a better fate than extinction. Other fine large Roses are: Countess of Oxford, Pride of Waltham, and Crimson Queen, a Rose somewhat confused in shape, but of that rich blood-red colour with velvety shading that one cannot but admire, and I think there is no Rose possessing such massive foliage as this one; Gustave Piganeau is immense, but a poor grower; Mme. Isaac Periere is a splendid garden Rose in every way, and its sport or seedling, Mme. Verrier Cochet, which I thought at one time to be like the former, but I now know it to be quite distinct. Star of Waltham is grand at times, but not certain; Marchioness of Londonderry, very large, nearly white, is undoubtedly best when half open. It is of a bad colour when fully expanded, so I would advise that the blooms be cut off ere they reach this stage. Rev. Alan Cheales, quite a Paeony-like Rose, evidently from John Hopper, is an excellent variety for the garden; La Duchesse de Morny, another beautiful and fragrant Rose, is very vigorous in growth and so good in form as to now and then receive a medal as the best H.P. in the show. I must not forget Ulrich Brunner fil. Of all red Roses this one may be relied upon to do well under any circumstances. It grows freely from cuttings, and is, in the opinion of our best judges, one of the most satisfactory Roses grown. Magna Charta is also worthy of extensive planting. Although it never even so much as gives a bloom in autumn, it still remains one of the showiest of summer kinds and is very fragrant.

Quite a number, if not all of the Roses named above, are capital kinds for greenhouse culture. There is no difficulty about the culture of such. Anyone can grow them who possesses a pit or greenhouse. The Hybrid Teas would naturally contain some large-flowering varieties, seeing that they partly sprang from the last-named group. Lady Mary Fitzwilliam is very good, and its white sport, White Lady, superb. Early in June there is no Rose in our large collection so showy. Bessie Brown will rank among the large-flowering kinds, and I have seen Antoine Rivoire fully 5 inches across. Captain Christy is well known as a showy garden kind, and it is equally fine under glass. Denmark is one of the best and sweetest in the Rose-house, but it will not flourish outdoors. Among the true Teas Maman Cochet will be hard to beat in point of size, and, of course, its white sport is equally large. Souvenir d'Elise Vardon at one time was considered one of our largest Teas, but it is a poor grower. Mrs. Edward Mawley is well worth growing. It is superb in every way. ROSA.

Planting Tea Roses from pots.—

Those who intend planting Tea Roses this season will do well to have them in pots, and plant them at the end of April or early in May, just as they are commencing to grow. Lifting them from the open ground and planting them earlier is courting failure, especially if the position is an exposed one. Even when transplanted from pots, protection from cold winds must be given, nothing answering better than Furze or evergreen branches placed round and amongst them.

Mercantilla sulphate of quinine (not medical) in small granulated lumps.—I was given to understand that the above is a good deodoriser or disinfectant for a rain-water tank, and that it renders the water more beneficial for the ground for growing purposes. Could you kindly say the quantity to be used for a 200-gallon tank, and also point out in what manner it benefits the ground? I never use the rain water excepting for watering the garden.—J. C. IREAN.

I did not quite understand what you mean by "mercantile sulphate of quinine," but the

ordinary medical drug of that name would be useless as a disinfectant or deodoriser of rain water, and it would only act very slightly as a manure, certainly not sufficiently so to make it worth using. As you only use the rain water for watering plants, why trouble to disinfect the water? You need only clean out the tank every now and then if the smell of the water becomes unpleasant.—G. S. S.]

ROOM AND WINDOW.

INDOOR PLANTS IN SMALL POTS.

WHERE plants are kept permanently in the dwelling-house they will, of course, consist principally of subjects grown for the sake of their foliage, and among them the different Palms predominate, though second to no other plant for such a purpose is the universally cultivated *Aspidistra*. Plants that are kept indoors are often in a far from satisfactory condition, and in many cases this arises from the pots being too large. Where the treatment of plants is but little understood there is a great tendency to over-water them, and consequently when the pots are small and therefore full of roots there is far less probability of causing mischief by an overdose of water than would be the case if the plants were in larger pots and a greater quantity of soil around the roots. It is surprising what fine Palms can be grown in quite small pots if they are not allowed to suffer from want of water and are assisted by an occasional dose of some stimulant. There are now many concentrated manures that can be used indoors without any unpleasant effects, all of which are very good if applied according to the instructions. In using any of these manures for the first time, care should be taken not to overdo it, as it is far better to give two small doses than an excessive one. A little stimulant about once a month during the growing season will suffice to keep such plants as are above indicated in good condition.

A fruitful source of ill-health in the case of plants that are kept in a dwelling-house is that they are a good deal exposed to draughts, and are consequently subject to extremes both of temperature and water; for, while an excess of water must be guarded against (and the use of small pots does this pretty effectually), if fine-foliaged plants are once allowed to get too dry they are often irreparably injured. That annual repotting is by no means necessary in order to maintain indoor plants in good health is shown by an *Aspidistra* that I have kept in a sitting-room in a smoky district for seven years, during which time it has been repotted but twice, and it is now a splendid specimen in robust health. True, the watering during that period has been carefully done and the plant assisted with an occasional stimulant, while the foliage is always kept clean—another very important item. II.

Window boxes.—There is no time to be lost in making preparations for the summer display on the window sill. If boxes have to be made, then they should be got in hand and painted, in order to preserve them: a couple of coats, both inside and out, prevents a too early decay. Old boxes should be thoroughly examined, and any necessary repairs made. Those on which cork and hark have been fastened often require attention at the commencement of a season. It is not desirable to again use soil of a previous year, but new compost should be substituted, as plants are likely to give better results. Those who prefer dwarf subjects and sweet smelling flowers should remember *Mignonette*, *Musk*, and *Heliotropes*. Showy things, too, like *Begonias*, *Zonal* and *Ivy-leaved Geraniums*, and *Campanula isophylla* must not be forgotten. *Petunias*, too, flower exceedingly well in a place where there is plenty of sunshine, and in such a window I would certainly plant them. In a window box last year I saw *Verbenas* doing remarkably well. *Fuchsias*, as all know, are extremely showy, bloom well either plunged in pots or planted out in the boxes, and always please. Sometimes in the autumn, when flowers begin to drop off and the window boxes are first to show it, we wish we had other things to take their places. To this end it is advisable to grow on in pots (plunging them in the boxes

until wanted) such things as *Asters* and early-flowering *Chrysanthemums*, like *Alfred Fleuret*, *rosy-lilac*, *Harvest Home*, *brouzy red*, *tipped gold*, *Lady Fitzwygram*, *white*, *Doris Petro*, *white*, *Mme. Gague*, *mauve-pink*, *Mme. Z. Lionnet*, *orange-yellow*, *Anastasia*, *light purple*, *St. Crouts*, *lilac-pink*, *Golden Fleece*, *golden-yellow*, *Mme. Jolivart*, *blush-white*, *Mrs. Callingford*, *white*, and *Little Bob*, *crimson*, all of which are naturally dwarf and may be made even more so by pinching them back once or twice during the season. Very often, too, the odds and ends of plants that are too small for bedding out in May, and which sometimes are thrown on to the rubbish-heap, make useful things for the window boxes with care and attention.—WOODBASTWICK.

CHRYSANTHEMUMS.

HOW TO MAKE BUSHY PLANTS.
(REPLY TO "A. G.")

MANY of our best Japanese *Chrysanthemums* have a tall and undesirable habit of growth, and are in consequence of less value than if they were dwarf and bushy. The unfortunate fact in connection with these plants is that the tallest and most ungainly kinds not infrequently develop the most charming blossoms. It would be an easy matter to give quite a long list of delightful sorts which, for no other reason than that they are tall and unsuited for the purpose, are discarded for conservatory decoration. Anyone may, however, with a little more than ordinary attention, develop plants of a bushy character from those sorts known for their lanky growth. No better period than the present could be selected for commencing operations. We will assume that the plants are now making strong and sturdy growth, and at this moment each plant is represented by a single shoot. We will also assume that the plants were placed in their present pots some time ago, and are, in consequence, nicely rooted. The initial operation is pinching the shoots, and this is accomplished in the following manner:—Pinch out the point of each plant, doing this with care. The growth at the apex of each shoot being very brittle at this season, the pinching out of the point is carried out with ease. For a few days subsequent to the pinching or stopping, the plants should be kept rather drier at the roots than usual, not so dry, however, as to cause the plants to suffer. The object in keeping the soil rather dry is to induce the plants to break out into fresh growth, and this they will quickly do when treated in the manner just described. Some sorts respond with fresh growths from the axils of the leaves much quicker than others, and plants partaking of this character of growth generally make larger and better plants. In the course of a few weeks, assuming, of course, the cultural details usual for the season are being observed, evidence of rapid growth of the side shoots will be apparent. From this point the plants must be kept growing on unhindered, and if need be, they must not be repotted when the pots they occupy are full of roots. When the side shoots above referred to have attained a length of some 6 inches or rather more, they must in turn be pinched, as was the original single stem by which each plant was first represented. Observe the same rule as to keeping the plants slightly drier at the roots as before, and in a few days another series of lateral shoots will make their appearance. This pinching may be carried on all through the summer as each succeeding 6 inches of growth is made. It is astonishing to what dimensions some plants will attain by a continuous system of pinching out the points of the shoots. The pinching must be discontinued at a certain period. If a November display be desired, let the pinching be discontinued during the last week in June, and from this point grow on the resulting shoots to the terminal buds, which mark the termination of the plant's growth. If, however, a December or Christmas show of blossoms be preferred, give the plants their last pinching during the third week in July, growing on the resulting shoots to the terminal buds as before described. Terminal buds develop in a cluster at the apex of each shoot, and if useful decorative blossoms be desired, the more crowded buds should be retained

retaining only those of good shape and larger size. Never repot and pinch the shoots at the same time; a week at least should elapse between the operations.

Chrysanthemums—stopping and timing (J. L. M.).—Your plants represent both Japanese and incurved varieties, and as it is now too late to adopt the ordinary method of pinching followed in late March and early April, you had better now treat your plants as follows:—

Name.	When to pinch the plants.	Which buds to retain.
Mme. R. Cadbury	1st week in May	First crown
Sir H. Kitchener	3rd week in May	1st crown
Mrs. W. Cursham	1st week in May	First crown
Lady Ridgway	May 21st	First crown
N.C.S. Jubilee	Pinch the plants at once, and take up three shoots. Pinch each of these three shoots about June 25.	and grow on the strongest one.
Silver Queen	and grow on the strongest one.	ceeding individual shoot on each of those first taken up, securing the first buds subsequently developing.
Mme. Ed. Roger (inc.)		
Nellie Southam (inc.)		

By treating the last four sorts in the manner we have just described, the buds which are retained subsequent to the late June pinching will be the equivalent of second crown-buds.

FERNS.

HARDY FERNS.

In most gardens, large and small, there are places which cannot well be embellished by using flowering plants. Where most things fail, the more vigorous-habited, hardy Ferns will find a home. In dark corners or in the shade of trees they will thrive admirably, and once fairly established they will give no further trouble. It is a curious fact that many who do not grudge the labour and expense necessary for the culture of Ferns that demand the shelter of glass make little or no attempt to beautify their garden with our native kinds, which are not inferior to their exotic relatives in beauty of form and nobility of growth. Any fairly good garden soil will suit them, but, of course, they will attain finer proportions in a good compost of loam and leaf-mould. It is quite a mistake to suppose that rockwork or an elevated position of any kind is necessary for the well-being of hardy Ferns generally. Some kinds of lowly growth, such as *Asplenium viride*, *Ceterach officinarum*, and the *Holly* and *Parsley Ferns*, must have good drainage, but the robust-habited varieties do not need this accommodation, and in a general way do best when the roots are not raised much above the ordinary ground level. Planting them on rockwork, rootwork, or mounds deprives them of the moisture they so much need in the growing season. One of the very finest Ferns is the *Royal Fern* (*Osmunda regalis*). Nothing can exceed the beauty of this native species when it is in the enjoyment of the conditions that favour its growth. It is a grave error to place this, as is often done, in an elevated position, for it is in its native habitats invariably found where the roots get a liberal supply of moisture even when at rest. In damp woods, swampy places, or by the side of streams or pools of water this Fern attains such noble proportions as to render it one of the finest of the many things in cultivation that are valued for the beauty of their foliage and elegance of growth. The dampest place in the garden should be chosen for this Fern, and if the ground is well prepared and ample space allowed for development, the plants will in due time throw up fronds 6 feet or more in height. The exotic species of *Royal Ferns* are equally hardy and as worthy of being well cared for. They also delight in moisture, but are apparently longer in coming to their full size. The *Lady Fern* is much more worthy of a place in gardens than many of its varieties, and which are more curious than beautiful. The same may be said of the *Hart's-tongue*, the type, to my mind, being infinitely much more ornamental than the majority of its varieties, in many of which the free, vigorous growth natural to this Fern is in a great measure suppressed. There is a richness of verdure in the *Hart's-tongue*, that is particularly attractive, and which few Ferns, hardy or tender, possess in such a high degree. The *Hart's-tongue* will

grow freely in almost any kind of soil, but to see it at its best it should be planted in well-enriched ground. The best specimens I ever had were fed into a high state of luxuriance by a liberal dressing of rotten manure. The fronds were abnormally large and exceptionally rich in colour. There are several varieties of this Fern that are fairly rigorous and not difficult to please. The best are probably *crispum* and *angustifolium*, but, to my mind, even at their best they are not equal to the typical form, which exhibits greater elegance of growth than any of its numerous varieties can lay claim to. Among the *Polystichum* there are some that may be freely used in the manner above indicated. *P. aculeatum* is a noble Fern when fully developed, and the crested form of the male Fern is but little less vigorous and enduring than the common form.

In both large and small gardens room can be found for some of these common, but noble, habited Ferns, which merely require to be well planted and left alone, and require little or no attention for years together. In the wild garden, by the side of water, and under the shade of trees these native Ferns should be freely used. They give variety and add a charm to any garden, large or small. T.

GARDEN WORK.

Conservatory. *Franus triloba* is a very pretty double pink-flowered Plum, very easily forced, even when freshly lifted from the ground. When well grown it makes a very handsome bush. We have had a group of it in flower for some time, and can strongly recommend it either as a shrub in the border, or a pot plant forced into bloom at any season during the early part of the year. Thin the growths of *Tecomas*, *Passion-flowers*, and *Mandevillas*. If the house must be kept gay, it will be well not to spill much water about in dull weather, and the ventilation must be as perfect as possible without creating draughts. *Clivias* or *Imantophyllum* which have been brought forward in a warmer house may be grouped in the conservatory in the warmest part of the house. The *Amaryllises* are glorious plants and will keep in the conservatory longer than in a warm house. They should be lightly shaded if the sun is very bright. These are still high in price, but anyone with the command of heat can raise seedlings and work up stock. The seedling raisers of such plants as *Amaryllis* and *Clivia* have to wait some time for results, but they come ultimately, and upon starting with a dozen good varieties and hybridising the blossoms may expect something valuable, and all the seedlings from a good source will possess some value. Baskets for suspending should be rearranged or refilled with young thrifty plants now. *Asparagus Sprengeri* is a graceful plant in a good-sized wire basket. It is a strong-rooting thing and requires room for its roots. Under such conditions the growth is very free. The plants are easily raised from seeds in heat at this season, but time is required to make a good specimen. Bamboos may be divided and repotted now. This is a class of plants which, I think, ought to be cheaper, as they are not difficult to propagate or grow. The *Eulalias* are lovely pot plants for mixing with flowering plants, and merely require protection in winter. As the Indian *Azaleas* go out of bloom remove dead blossoms and seeds. Give the plants a thorough wash with the syringe and place in a warm house or pit to make growth and get forward for forcing next year. Look closely after insects and milder on Roses and apply a remedy.

Stove.—Nearly all plants may be propagated from cuttings now where there are soft young shoots from 2½ inches to 3 inches long. They must have a close propagating-case and a brisk bottom-heat. In small places where there is no regular propagating-house a small case can be improvised over the pipes in the front of the house that will strike most things, including *Gardenias*, *Euphorbias*, *Poinsettias*, etc. Have a bed of Cocoa-fibre, 6 inches or so deep, in which to plunge the pots. Most things will strike in sandy peat or leaf-mould, with a layer of sand on the top. Cuttings

air to the case every morning to prevent damping, and if bell-glasses are used for my choice thing wipe the inside of the glasses dry every morning. Change of position is important now, especially in lean-to houses; it prevents the plants growing one-sided, so to speak, by exposing all sides equally to the light, and a fast-growing plant can have a little more space allotted to it. Overcrowding at this season has a ruinous effect upon the plants as the foundation is being laid. In repotting growing specimens be specially careful about the drainage, and use only clean pots. Never sift the soil except it may be for potting off cuttings. Old rotten turf, with peat of a fibrous character, and plenty of clean sand, will suit most things. In giving last shift to *Gloxinias*, *Caladiums*, *Vincas*, and any other plant which requires more nourishment, a little dry old cow manure will be useful. Night temperature now 65 degs. Ventilate when the thermometer approaches 80 degs. Keep the atmosphere moist by damping floors. Never use hard water for syringing. Some things will require shade now in bright weather, but do not darken the houses more than is necessary to break up the sun's rays.

Ferns under glass.—These are growing fast now, and must not be crowded. There is a demand now for plants in 6-inch and larger pots for decoration, and a healthy plant in a 5-inch pot may now be made into a handsome specimen by giving it a larger pot and room enough to grow. The indoor fernery must be shaded now from 10.30 to 2.30, and abundance of moisture used on paths and stages to keep things in a healthy condition. Tropical Ferns must have a night temperature of 60 degs. to 65 degs., and ventilation to harden the fronds, especially if required for cuttings. When the temperature rises to 80 degs. plants with the pots full of roots must be well supplied with water. Market growers, to rush plants on speedily, use stimulants, but the growth made under the influence of stimulants will not keep long in condition. It is better to grow more naturally for house decoration, and if stimulants are used only plants which are getting pot-bound should be dosed. They should be used in a very weak state. If more loam is used in the soil the growth will be firmer and more lasting. When plants are grown only for exhibition a more liberal regimen may be adopted to induce extra luxuriance: the lasting powers need not be studied so much.

Night ventilation to fruit-houses.—In old-fashioned houses there was always plenty of night ventilation through the laps of the glass, but with modern houses, with large squares of glass and the laps fitting close, a little chink of air along the ridge becomes desirable from this onwards. In my young days, with old-fashioned houses, I never saw a trace of mildew. It is only since the closely-glazed houses and inside borders were introduced that mildew has given so much trouble. The two evils to be guarded against in fruit-growing under glass are deficient ventilation (especially early in the day) and dry borders. Of course, in experienced hands the inside border and the close-glazed house are a success. In giving night ventilation the outside temperature has to be taken into account, as we do not want to increase the fuel bill.

Window garden.—From present appearances this is going to be a busy time for the outside window gardeners. Those who use *Begonias* in window-boxes must provide good soil. Red, white, and blue are likely to be the colours in demand. Red and white *Begonias*, with blue *Lobelias* along the front of the boxes hanging over, will look well, and be a breakaway from the *Geraniums* and *Marguerites*. Pink and white *Geraniums* with blue *Lobelias* will make a change. What is wanted is reliable plants—not miffy things that will not grow.

Outdoor garden.—Fill up vacant places in herbaceous borders with suitable plants. To my mind, scarlet *Geraniums* do not agree well with herbaceous things. I would rather fill up with annuals, either hardy or tender. Stocks and Astors can generally be utilised. *Gladioli* and *Hyacinthus candelarii* in groups may be dropped in where there is room. Though the *Hyacinth* is not a front row plant, it is a very charming bed last season. Plant

with a groundwork of dark *Heliotrope*. The centre was dotted over with *Hyacinthus candelarii*, and nearer the margin the dot plants were *Gladioli brechenleyensis*. Of course, it is too soon to plant anything tender yet, but the *Hyacinths* and *Gladioli* could be planted now, and the site of each bulb marked with a small stick to prevent disturbance. The newer forms of *Pentstemons* are lovely in a mass, and the dwarf forms of *Antirrhinum* are very effective. There are distinct colours of white, yellow, and crimson which come true from seeds, and are among the most effective and cheapest plants for massing. If the seeds are sown in heat and the plants pricked off and hardened, they will go out as soon as ready, and will flower early. *Cannas* and other tropical plants should have a sheltered spot, and the soil be deepened and enriched. These are good town plants if well nourished. *Japanese Anemones* will move well now.

Fruit garden.—Bush fruit-trees and dwarfing stocks require a good deal of support in the way of mulchings, and liquid-manure may be given with advantage during the summer to heavily-cropped trees. Never dig near the trees with a spade, nor yet plant anything within 3 feet of the stem. In the matter of manuring such trees there is always room for judgment. The man on the spot, if he has had experience, knows the best course to pursue. But with this provision it is certain that fruit-trees might with advantage have this help, and it should be given in the way best calculated to obtain the end in view. It is not always wise to pile a mound of manure round a tree, though this is often done. Very often a mulch of compost made from the clearings of the rubbish-yard, exposed to fire to char it, will be more beneficial. Finishing touches may be given to the fruit by applications of nitrate of soda when the fruits have reached a good size. The fruit-grower has a good deal to learn before he has a full command of the situation and its possibilities. Open-air Strawberries are looking well, and if not already mulched keep the surface clean and loose by hoeing. Top-dressings of soot may be given on dry, porous soil. Salt in small quantities may be used as a check to drought—6 lb. or 7 lb. per square rod, will injure nothing if used now.

Vegetable garden.—Successional crops of many things must be sown now, including Peas, Beans, Spinach, Beet, Winter Greens of various kinds, Lettuces, Radishes, Vegetable Marrows, and ridge Cucumbers. Carrots are not much grown, except in large gardens. The first sowing is usually made in small pots, two or three seeds in each in heat, and when the young plants appear, the strongest is retained and the others pulled out. The plants are hardened off and planted in the trenches in May. The main crop may be sown directly into the trenches in patches 15 inches apart, to be thinned to one plant when the selection can be made. A sowing of French Beans may be made on a warm site. Scarlet Runners for the first crop may be started in boxes to be planted out when the weather is quite safe. Sow Spinach Beet and New Zealand Spinach. These are the best substitutes for Spinach. Plant Cucumbers in frames or anywhere under glass where a little heat can be given to start them. Tomatoes will do now in pits and frames if covered at night. Get them sturdy and well-hardened. E. HUBBARD.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

April 21st.—Planted Violet cuttings for lifting in autumn. The cuttings were rooted in boxes in a frame in the autumn, and are now nice little plants with plenty of roots. They are planted a foot apart, in well worked land, in an open situation. Divided several old plants of *Cypripedium* to make stock, the compost used being very fibrous peat, crushed charcoal, and chopped Sphagnum. The pots are half filled with drainage. Planted more *Gladioli*, chiefly *Brechenleyensis*.

April 22nd.—Looked round herbaceous borders and lawn beds to renew labels. Removed *Dabbins* to cold-frames to harden. We are sowing *Geraniums* chiefly, as we find

them more useful for cutting. Stopped and tied Fuchsias and Heliotropes. The Heliotrope makes a sweet plant for mixing in the conservatory. Some of the new varieties have very large trusses of blossom. Planted several hardy things in kitchen garden for cutting.

April 23rd.—Mulched Figs in pots with rich compost, in which a little Clay's fertilizer is mixed. Figs when full of roots will take a good deal of nourishment. Finished training Figs on walls. These trees have never failed to bear a crop since the roots were lifted, and a foundation of brickbats and old mortar rubble was placed under them. Sewed more Lettuces and other salad plants. Tied up early Lettuce plants to blanch. Sowed Chervil.

April 24th.—Planted out Pentstemons from cold-frames. The cuttings are struck in autumn in cold-frames. Pricked off Stocks and Asters in frames from which early Potatoes have been lifted. Finished planting Asparagus. Stirred soil among Violas in beds, which are now very bright. Put in cuttings of some new Phloxes; we are striking these in heat. Divided and made new plantations of Pyrethroms and Michaelmas Daisies. The Dorotheums are amongst the brightest things in the garden now.

April 25th.—Moved a lot of forced shrubs to conservatory. These included Rhododendrons, Deutzias, Prunus triloba, Weigela, standard scarlet Thorns, Laburnums, and white Lilacs. A very small amount of forcing has sufficed for this lot. A few standard plants of the Silver Maple (Acer Negundo variegatum) are useful among dark-foliaged plants, and are easily grown in pots. Shifted on young Ferns and Palms. Small Kentias in thumb pots are being used instead of small Ferns as table ornaments.

April 26th.—Planted out a lot of late-flowering Chrysanthemums for lifting in autumn. Looked over Peach-trees on wall to keep down insects. Sowed more Winter Greens. Sowed Cucumbers and Melons to fill up frames when the bedding plants are taken out. Planted a large bed of Iceland Poppies for cutting. Old Hyacinth bulbs which have been forced have been planted along the front of a shrubbery border. Sowed more Sweet Peas and other hardy annuals.

POULTRY.

Death of chicken (C. Burton).—The bird sent for examination appears to be in a perfectly healthy condition. Great care is necessary at this season, when the outside temperature is so variable, to properly regulate the heat of the rearer, as chickens brought up artificially are very liable to contract a chill and suffer from cramp. A thermometer should be used with the rearer, which should be regulated to 85 degs. for the first fortnight, and then gradually lowered until after a month or five weeks, allowing another week in cold seasons. You appear to be feeding your chickens correctly; in fact, there is nothing better for the purpose than the prepared food you are giving them. Do not fail to give green food, such as Grass cut fine, Chickweed, and Lettuce, and mix a little grit in the soft food. After three weeks grain may be given instead of grouts, remembering that a variety of food is of the greatest advantage in the successful rearing of chickens.—S. S. G.

United Horticultural Benefit and Provident Society.—The monthly committee meeting of this society was held at the Caledonian Hotel, Adelphi-terrace, W.C., on Monday evening last, Mr. C. H. Curtis in the chair. The minutes of the last meeting were read and confirmed. Thirteen new members were elected. Two cheques were granted from lapsed members' accounts, one being for £1 8s. 9d. to widow, and the other for £13 16s., claimed by lapsed member on reaching sixty years of age. Cheques were also granted for payment of two members' quarterly allowance from the Benevolent Fund, also for printing, and Secretary's salary. A member asked permission to be transferred from the lower to the higher scale of contribution, which was granted. It was resolved to commence the committee meetings in future at 7 pm. instead of 8 pm.

BIRDS.

Blackbird ailing (J. Barrett).—The loss of voice arises from the bird having taken a cold. A little glycerine (about six or eight drops daily for a week) in the drinking water will give relief. Give, also, a small piece of mutton suet or fat bacon for the bird to peck at. This trouble may generally be attributed to want of proper treatment during the moulting season, when too much care cannot be taken in protecting from draught and sudden changes of temperature and supplying food of a more generous quantity than usual. You appear to be treating your Blackbird correctly in the matter of food. Do not hang the cage out-of-doors till the weather becomes warm and settled. The glycerine may be continued if it does not give relief at the end of the first week.—S. S. G.

Food for Blackbirds and Thrushes (Navy).—Those birds are easily reared, and may be fed upon Oat-flour (known as Fig-dust) and Pea-meal mixed with milk or water to the consistency of a moist paste. They may also have mealworms, ants' eggs, and, occasionally, a little raw lean meat, shredded finely. Feed, two or three mouthfuls at a time, every quarter of an hour, and frequently drop a little pure water into the mouth of each nestling as they get older and the paste is given in a drier state. The staple food for these birds when they arrive at maturity may consist of the above paste, but mixed to a crumbling state. This, with almost any kind of cooked food that does not contain salt, such as puddings, vegetables, and custards, will keep these birds in good health. A snail is a great treat, and if a stone be provided, both Blackbirds and Thrushes will amuse themselves by breaking the shell of the snail upon it, as in their wild state, in order to secure the contents. It is necessary to supply abundance of water both for bathing and drinking.—S. S. G.

LAW AND CUSTOM.

Right of tenant to remove Rose-trees.—A look a furnished house by the month, and a year later planted some Rose-trees in the garden. Two years after taking the house he left it. Is he entitled to remove the Rose-trees?—D. C. R. (He has no right to remove the Rose-trees. Such things once planted in a private garden belong to the landlord.—K. C. T.)

Agreement to surrender tenancy.—I let a house to a tenant at a yearly rental of £32, payable quarterly. In February he gave me notice to quit, but expressed his wish to quit on March 23rd or in June, if I would allow him and take the house off his hands, and I expressed my willingness to this course. In March he said he had taken a new house, which would be ready for entry on May 1st, when he would remove. I let the house from May 1st to a new tenant, who has gone into apartments and stored his furniture in the meantime. I now find that the present occupier has not taken a house, and has told me outright, "What is my position? Could I maintain an action in the county court to recover damages, as I shall have to give the man who has taken the house some compensation? My tenant did not give me written notice.—J. H. S.

[I am afraid the contract for surrender was too informal, and that you cannot recover damages, unless, indeed, your old tenant was a party to the arrangement with your "new tenant," and gave him to understand that he was quitting. If this could be clearly proved, you might recover damages by action in the county court.—K. C. T.]

Damage to crops by felled timber.—In September last I sold some oak-trees to a timber merchant, who cut them down in November, and they still remain on my land, which is let to a neighbour. I wrote to the timber merchant more than a month ago, and asked him to remove the timber at once, and he wrote back promising to do as I requested, but the timber lies there yet. My tenant says he will make a deduction from his payment of rent because the Grass is damaged and the situation is dangerous for his stock. Can I sue for damages? I have preserved the letter.—PERPLEXED.

[The question is this: Have these felled trees been allowed to lie unmoved for an unreasonable time? The answer depends upon the nature of the trees and the terms of the bargain of sale. An express stipulation as to the time within which removal is to be effected should always form part of the contract of sale, and this avoids any disputes as to what period is "reasonable." You should write again to the timber-merchant, reminding him of his promise, and if he does not at once carry out his undertaking you may sue him for such damages as you or your tenant may have sustained.—K. C. T.]

CORRESPONDENCE.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow their rules: All communications should be clearly and concisely written on one side of the paper only, and addressed to the Editor of GARDENING, 17, Finsbury Street, London, E.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation, if any desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper, and not more than three queries should be sent at a time. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, queries cannot always be replied to in the issue immediately following the receipt of their communication. We do not reply to queries by post.

Naming fruit.—Readers who desire our help in naming fruit should bear in mind that several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents simple specimens of fruits for naming, these in many cases being multiple and otherwise poor. The difference between varieties of fruits are, in many cases, so trifling that it is necessary that three specimens of each kind should be sent. We can undertake to name only four varieties at a time, and these only when the above directions are observed.

PLANTS AND FLOWERS.

Loam (Ella B. Marjory).—Loam is the top soil of an old pasture which has been stacked away for a time to allow of the Grass rotting. This is called turfy loam, and is valuable for potting on account of the decay of turf and numerous fibrous roots, these keeping the compost open as well as supplying plant food in itself and in a condition easily assimilated.

Paeonies (J. Cole).—We see no reason why you should not attempt the culture of Paeonies, as most gardens contain spots so shaded that few plants will thrive in them. In such places Paeonies would do well, and the colour of the flowers would also be much richer, while the blooms would last longer than in the full sun. Few plants are more fitted for the wild garden.

Clematis in pots, soil for (Miriam).—The soil for Clematises in pots should consist of good loam and rotted horse or cow-manure, plenty of drainage being given. After they have done blooming, they may be removed to the open air. Clematises must when growing be well attended to with water and rich feeding. See our article in the issue of December 28, 1901, p. 57b.

Plants for stone edgings (A. J. Roberts). For such a purpose there is great variety. The Mossy Rock-foam make excellent edgings growing among the stones. You will also find Tufted Fansia, Thrift, Androsifas, Veronica, alpine Phloxes, Sun Roses, Aralis, Candytuft, Pink, dwarf Harebells, and Moneywort (Lysimachia) very suitable. Wild Strawberries, too, look well when grown among the stones, as you intend doing.

The Marguerite Daisy-fly (A. Suberbie).—The leaves you sent are infested by the grub of the Marguerite Daisy-fly (Phytomyza affinis). The leaves which are too much injured to be of any further use to the plant should be cut off and burned. The others should be held up against the light and pinched where the grubs are seen, or a needle run through the leaf, if it pierces the insect, will be equally efficacious. As there are several broods of this insect during the summer, it is important to try and extirpate the first brood.

Plague of earwigs (R. Humphries).—The only way to get rid of earwigs is to trap them. Earwigs may be trapped in crumpled-up sheets of newspaper, loosely folded cloths, the hollow stems of plants, such as Bean or Sunflower stalks, or small Bamboo. They are said to be very fond of beer and treacle. You might try securing a sheet of brown paper with some, and then crumpling it up and placing it where the insects are. In the morning open the traps over a basin of boiling water, or water that has a little paraffin oil floating on the top.

Chrysanthemum—questionable exhibition (Bep).—We do not know the variety G. J. Bird mentioned in your letter. The only one we know of a somewhat similar name is Lubert Laine, which is an excellent white December-flowering Japanese. The other sorts mentioned in your list are occasionally met with at the November shows, but they are hardly up to the standard of quality now required in severe competition. For the embellishment of your greenhouse or conservatory, however, the seven sorts make a pleasing and varied display.

Transplanting Bracken (A. M. W.).—Carefully dig up some of the black underground creeping roots, and replant them thickly at about 3 inches deep. In digging up the roots care should be taken to select only those which have a green bud at the tip, as without this the roots will not start. Now is a very good time to carry out this operation. You do not say where or how you will obtain supplies, and if you have to dig it from old-established areas you will find material assistance in selecting the most shallow ground. In this way you can obtain the best roots.

Using bones as manure (G. Paddy).—Where it is possible in any way to steam bones so as to soften them, then to crush them up, capital manure is made. If that cannot be done, then smash them up with a big hammer or weight, making them as fine as possible, then adding a pint to a bushel of potting soil. If the material be not very fine, then add double the quantity, as bone not very small is long in becoming decayed, and, if not very fine, will be mixed with wood and hard, this rendering them all the more easily crushed. Some persons use fish pieces of bone to mix with drainage in their flower-pots, as the roots will feed upon them.

Plants for glasshouses (Acerina).—By running a board along both sides at the front and filling in with soil, you could grow four plants of Tomatoes on each slab, and train up to the roof on a single stem. The front board should be 9 inches deep and placed a foot from the outside, the cavity thus formed to be filled in with good soil. On top of and under the Tomatoes you could grow Peppercorns, Heliotropes, Tuberosus Begonias, Celaninus,

VEGETABLES.

SOWING ASPARAGUS.

OWNERS of small gardens seem to be shy of taking up the growth of Asparagus. Many appear to think a long time is necessary ere a profitable return is realised. This in some instances is quite true, the land often accounting for it. In some gardens an Asparagus-bed soon comes to a profitable state, in others it is very slow. An Asparagus-bed, when well made and properly treated afterwards, will last almost a lifetime. It has been known to remain in good condition for over fifty years, while in other land, unless special preparation is made, it will last only a few years. Stagnant ground is not good, nor is very heavy land, when ordinary surface planting only is adopted. Such instances require drainage and raised beds. In other cases, on deeply-dug and well-manured ground the Asparagus will do well for many years. Seeds may yet be sown in drills, drawn as for Spinach or Beet, about 18 inches apart, the plants thinned when they appear above ground to about the same distance asunder. Beyond this all that is necessary the first year is to keep the surface free from weeds by frequent hoeing. Beds are not strictly necessary except, as previously intimated, on heavy and ill-drained land. There is not a large selection of sorts, but there is at least sufficient for every purpose, and no mistake can be made in a rigid choice. Some, however, such as Connover's Colossal, produce large heads and fewer of them, while the Purple Argenteum gives medium heads in greater numbers. It may be well, perhaps, to choose two sorts, then a fuller crop would result. It is sometimes disappointing when cutting commences from a bed of Connover's Colossal to find how few heads can be cut at a time. At the same time, if large Asparagus is wanted at any cost and without extraordinary cultivation, then choose Connover's. Some cultivators in sowing use a setting-stick or dibber for Asparagus, instead of drawing drills. In this way less seed is necessary, and certainly less labour afterwards in dealing with the seed-bed. The use of the dibber can be necessary that the seeds are not buried too deeply, 1½ inches being ample. If ground is not available now for making beds, there is no need to delay sowing if it is intended to make future plantations. The seeds may be sown thinly on a bit of spare ground now, left to grow until next April, or, if need be, for two years. Strong crows will then be available for lifting to plant permanently, and it is better to do this than to sow permanently on ground not well prepared. In deeply-trenched and heavily-manured land, Asparagus soon reaches a profitable state. Growers living near the shore and who can procure Seaweed find Asparagus culture much more profitable from the employment of this as manure. Inland growers must depend on animal or artificial manures and salt. A word of caution is necessary in the employment of heavy salt dressings on clayey land, as these make the

soil cold and wet. Sandy soils are benefited by using salt, while clay lands may be practically spoilt.

WORK AMONGST TOMATOES.

EVERY season Tomatoes are grown in increasing numbers, both for market and private consumption. Now we see on all lands those who have glass-houses of any description making provision for their culture. Span-roofed houses, as soon as arrangements can be made to turn out the plants intended for bedding, etc., are converted into Tomato-houses; others, perhaps, who need only a few for their own supply are content to devote one side of the house. Then, again, one finds them grown under frame-lights, raised so as to afford them the necessary head room, on warm borders outside, and, indeed, every place in and about a garden where sunshine is felt at all, proving that Tomatoes are regarded with favour. Each year finds growers of Tomatoes for the first time who sometimes at the outset fall into errors common enough to those who have had little or no experience. The present is a convenient time to commence, and I therefore offer a few remarks to the beginner who proposes to grow them under glass. Select a sort noted for its cropping qualities, and, if possible, choose sturdy, short-jointed plants in preference to those long and spindly, even supposing the selection means a week or a fortnight's delay before cutting the first fruit. If it is proposed to heat the house—at any rate, during spells of cold weather, which not infrequently occur in April and May—it will be advantageous, often giving them a start, as coming out of warm-houses, where they have been previously, to a cooler atmosphere, the first trusses of bloom fail. On the contrary, if heat cannot be applied, then it is often desirable to wait a week or two until warm weather has fairly set in. The soil need not be rich to start. There is no necessity to add manure of any kind at the start, this often causing the plants to make a bit of useless growth. The turf should be fibrous, so as to bear chopping up, avoiding compost of a loose nature. This is a mistake frequently made, some using soil light enough for potting Fuchsias, for instance, instead of giving Tomatoes what they really need—a strong, firm, turfy loam. Whether pots or boxes or beds are used for their culture matters little. It will be quite time enough to feed the plants when the first truss of fruit has set, and no manure of any kind should be administered before. Then with benefit one may give liquid-manure made from sheep or cow droppings, guano, etc. At this stage one can vary the food, and when in full bearing increase the quantity, but at first once a week liquid-manure will be sufficient. In small houses, Tomatoes grown on a single stem find most favour and are to be commended, as, where this is carried out, too much space is not taken up with foliage, and thus light reaches other plants that may be growing in the house. The single stem for amateurs is much the best, this, of course, implying the removal of the side shoots in their early stages. As suggested, I would select a

variety noted for its good cropping qualities and early ripening, even supposing the fruit runs rather small, for it is the moderate-sized fruits that find the most favour. Such varieties are Earliest of All, Early Ruby, Sutton's Main-crop, Abundance, and Hathway's Excelsior. Yellow sorts are, for some reason, rarely grown by the amateur. They are just as easy to grow, possessed of agreeable flavour, and are pretty also.

LATE SEAKALE IN OPEN GROUND.

IS the culture of late Seakale in the open there is no need for manure or heating materials of any kind, and given good land, richly manured, the plants require little attention. There are other advantages, such as size of produce, improved flavour, and the value of what may be termed a choice vegetable at a time when good produce is none too plentiful. There is a ready demand for Seakale, which is of greater value when produced in this way, as the flavour is superior to that of forced roots. To get good supplies root cuttings planted early will provide the supply for the same month the following year, though to get strong crows the size of one's wrist two years' growth in the same position is advisable. There is then no waste, as the produce the first year will be of a fair size and pay for room occupied. Good land, an open position trenched and manured, the manure being put into the bottom spit, are what the roots delight in. Though Seakale will thrive in any soil, it will repay good culture by size of heads, and, being a gross feeder, requires plenty of food.

As regards position, a portion grown on a north border will extend the supply, but it may not be required so late, and in planting, it must be remembered the roots have to remain longer than required for forcing material. Two feet between the rows, or even more, and 18 inches in the row are none too much, as with good land the leafage is plentiful, and there is no gain in crowding. The roots are started previous to planting in frames, as this gives them a longer period of growth, the crown being half an inch long, and the base of the root or set bristling with a mass of thread-like fibres. Plant the sets in drills in preference to dibbling them in, as then they can be regularly placed and the roots preserved. When the tops are well above the surface a few weeks after planting, the growth to each set is restricted to the strongest crown. As growth increases, salt or, what is better, fish-manure is placed between the rows in showery weather and raked in. The flower-heads are removed as they appear. Covering of the crowns to blanch the Kale is best done in February if required late, but previous to this a good mound of coal-ashes placed over the crowns when the tops are decayed and cleared away will do good, as the ashes are a protection from slugs and prevent breakage when covering. If the ashes are placed 4 inches to 6 inches thick ridge-shaped, the plants will be ready for their spring covering later for this. Leaves partially decayed are used in quantity from 1 foot to 1½ inches deep. It is useless to cover with a small quantity the strong growths

soon push out at the sides and become green if exposed. During growth it is readily seen where to cut, the leaves being very strong and well blanched. All may not have leaves, but if ashes are used as the first covering, fine soil banked up ridge-shape answers well. When litter is used the tops push through so quickly that the heads are not blanched so thoroughly as with a heavier covering.

For late supplies in the open the old common form with purple tips at the end of the shoots is the best, this being much stronger than the Lily-white, which in wet seasons is not so robust, making also smaller growth. The old form with sufficient covering is white enough for all purposes and of better flavour. After cutting the produce the second year the beds may be destroyed.

EARLY POTATO GROWING.

The following has been issued in pamphlet form by the Department of Agriculture and Technical Instruction for Ireland:—

The cultivation of Potatoes for the early market is undoubtedly one of the most profitable branches of agriculture, provided the produce can be put on the market at the beginning of the season while high prices still obtain. In May phenomenally high prices are procurable; any time in June the price is good enough to ensure handsome profits; the first half of July is, as a rule, better than the ordinary late or maincrop, and the latter half of July as good as winter marketing. With the advent of August prices often fall to a very low point, and the risk of disease being very great, only those growers who are in favoured positions as regards markets and freightage can survive. It should be borne in mind that the cost of production is much greater than in the case of the late crop, and unless several pounds sterling per acre more is received for the early crop it is not profitable. Within the last twenty years great developments have taken place in this industry. Foreign countries have participated in a trade which was thought impossible to them and in our own country the crop has been greatly accelerated. The season opens in April with Potatoes from Malta and Teneriffe. In May great quantities are poured into our markets from Jersey and Cotes du Nord, France. Strangely enough, the next place in point of earliness is a strip of seaboard on the west coast of Scotland, where for 50 miles in Ayrshire and Wigtonshire the Gulf Stream exercises a beneficial influence directly through the North Channel, and renders that district singularly immune from spring and May frosts. The Ayrshire season commences generally about the middle of June. Good crops ready to raise at that date are worth £40 per statute acre, and are sold growing to merchants, who take all further risks and bear the expense of raising, the farmer having no more to do except cart the Potatoes to the nearest station. Ireland's share in this lucrative industry has hitherto been small, although her physical conditions are extremely favourable. It would not be possible to approach the earliness of the Channel Islands, but what can be done in Scotland may assuredly be improved upon in Cork and Kerry, subject to the same ameliorating influences in even greater degree, 200 miles further south, and possessing ideal soil. The east coast of Ireland does not enjoy so mild a climate, but whatever is lacking in that respect is compensated for by contiguity to markets and greater facilities for intensive farming.

Early Potato-growing has long been practised in County Dublin, and at one time Scotch markets were largely supplied from there. Even now it is perfectly wonderful what has been achieved at Rush, by a race of shrewd and hardy men, whose ceaseless and laborious industry deserves a better reward. By the adoption of some of the new methods for accelerating the crop, they can in some measure recover their lost supremacy, and Ireland generally may to a very large extent participate in the extremely profitable industry of supplying England with early Potatoes. Soils have considerable influence on earliness. Sandy loams are best, red or grey. It is wonderful what can be done even with poor sand under favourable circumstances and with generous treatment. Here, again, Rush may be cited. Much of the soil there appears to be drifting sand, and farmers have to resort to an expedient of facing it with straw and seaweed

to keep it from blowing away and laying bare the Potato sets. Still it bears good crops of Potatoes. Black lands or bogs are not suitable for early Potatoes, as the frost seems to grip more keenly there, and, besides, the sample is not so nice, nor is the quality so good. As the success of an early Potato crop depends chiefly upon the date at which it can be marketed, there is a constant striving to accelerate the crop. Considerable success has attended these efforts, and the date of raising has been put forward a fortnight to three weeks. This acceleration has been achieved mainly by three causes—viz.: Seed—the selection of early tuberizing varieties; sprouting the seed in boxes before planting; manuring.

THE SELECTION OF EARLY TUBERIZING VARIETIES—

that is, kinds that commence to form young Potatoes at an early stage of their growth, and which grow to root simultaneously with the top—has resulted in a great gain to earliness. At the same time, something has been lost in quality, and occasionally, in a wet season, one is apt to sigh for the good old Red Rog Kemp, which has been supplanted by less tasty kinds. The public, however, will have early Potatoes, and the business of the farmer is to produce what is wanted. In purchasing early seed it is obvious that purity is most important, much more so than in the case of a late crop. In a late crop, if there should be a sprinkling of another late sort, they will ripen together, and it may not matter much in the marketing, but if there be present in an early crop a mixture of late Potatoes it is fatal. Great care should therefore be exercised in selecting, that the stock should be true to name and pure. Another consideration is, what is the best change of seed? Whatever has been found to suit for the late crop will make an equally good change for the earlies, with this exception, that Potatoes grown on black moss or bog do not make the best seed for earlies, as they germinate and mature more slowly than those grown on red or grey soil. To determine the best variety to cultivate is a matter of some difficulty. A sort that does well in one climate may not suit another, and what does well one year may do badly the next. Then the fashion of the market to which the produce is consigned has to be considered. Some will only have them round in shape and white in flesh; others will only take Kidneys; while all are more or less shy of lemon-fleshed sorts, wherein they show great lack of discrimination, as these are often of the best quality. Exhaustive experiments with early varieties are being made by the Department of Agriculture, and, no doubt, by another year an authoritative pronouncement will be given upon the best sorts to cultivate. So far as Scotland is concerned, Early Puritan undoubtedly holds the field, and has probably had a longer tenure of life and popularity than any other of the same class. It is round, white, very early, and of good enough quality to hold the market for a few weeks. It is an American variety, which has been in commerce in this country since 1884. It is consequently of an age when its vigour may be expected to flag, but its successor has not yet arrived. In Jersey only Kidney-shaped tubers are grown. Flukes and Ash-leaf prevailing. If a Kidney is desired, there is one new sort which deserves mention, Duke of York. It is early (on the heels of Puritan) and far surpassing Puritan for quality and flavour. It is, however, long-shaped and has a deep yellow flesh, which detracts from its popularity in some markets. Several new seedlings of a first early class have recently been brought out which promise to meet a want. Further notes will be given in a subsequent issue. M. G. WALLACE.

NOTES AND REPLIES.

Young Nettles.—Will anyone kindly inform me whether young Nettles are ever used as, or instead of, vegetables for food?—NORTH WALKER.

Cabbage Sutton's Flower of Spring.—This new Cabbage undoubtedly has a future before it, as it is as early as Ellam's and equally as well flavoured. Being of small size and having but few outer leaves make it invaluable for small gardens, as it may be planted thickly. The flavour is excellent, and it is not so liable to run to seed prematurely as some. I believe it is very hardy, as it is already a favourite

with market growers, and they do not, as a rule, grow tender varieties. My favourite early varieties are Flower of Spring, Ellam's Cocoa-nut, Meio's No. 1, and Nonpareil.—J.

Potato Snowdrop.—All who appreciate florify, good flavoured Potatoes should grow Snowdrop. I am aware it is more liable to disease than some, especially in wet seasons, but its good, all-round qualities entitle it to a place in every garden. I do not recommend it for heavy, retentive soils; but for light and medium soils there are few that surpass it. The tubers are Kidney shaped and well formed, the eyes being shallow, the skin clear, and the flesh beautifully white when cooked. Added to this, it crops heavily, and, although fit for use in August, will keep sound till April.—CHOMER.

Endive Frazer's Improved Broad-leaved.—This is one of the most valuable Endives in cultivation, and the best for small gardens. It is very hardy, resisting frost and damp well, and does not run to seed so soon as some. Being of large size, it requires plenty of room, both when making its growth in summer and when placed in frames in autumn. The seed should be sown about the second week in July, and the young plants well thinned out and finally planted 9 inches apart in good soil. If kept well watered and free from weeds they will grow into large plants by October, when they should be lifted with good balls of soil and planted in a frame free from drip.—I. L.

Sowing and thinning Beet.—Although Beet is an important vegetable, it is often seen in poor condition, the roots being large, coarse, and stringy. This is generally the result of growing it in too rich soil and over-thinning the plants. It should be grown on ground that was manured for a crop the previous year, and the seed should not be sown till the middle of April. The ground should be made very firm, and the seed sown in drills 1½ inches deep and 12 inches apart. Sow thickly, as if the plants are crowded the surplus ones cannot be thinned out without loosening the rest, which is an evil. Thinning should be done piecemeal, as sparrows sometimes attack the young plants. To ward them off, dust the plants over occasionally with wood-ashes. At the final thinning leave a space of 8 inches between the plants. I cannot understand why some still grow the large, coarse varieties, as there are now so many of medium size. One of the finest Beets when obtained true is the Cheltenham Green Top.—SERRAUX.

Lettuces under glass.—Like Mr. Crook, I sowed Lettuces in a box in the late autumn, standing them on a shelf in a cool-house. These grew, and by the end of January were planted out in a slightly heated pit, without the aid of a manure-bed. By the end of March I was able to cut nice heads, which were so crisp that the most careful handling was necessary to preserve the leaves from being broken. Necessarily, those who have no frame accommodation must depend entirely on the open-air plantations, but for salad there is at this time of year scarcely any comparison between plants grown in frames and those produced under more natural conditions. Commodore Nutt and Tom Thumb are excellent for frames, a later and larger one being Paris Market. On the open borders the old Hammersmith has stood uncommonly well—scarcely a blank appears among them. Sutton's Monarch, too, came out well under winter culture. This has a great value for the summer, standing drought better than many Cabbage Lettuces, and a winter's trial proves that it is equally good in resisting extremes of cold as well as heat. A sowing under glass early in the year brings plants on for succession, and, if carefully hardened off, can be planted out under the shelter of walls having a south or eastern aspect.—W. S.

Photographs of Gardens, Plants, or Trees.—We offer each week a copy of the latest edition of the "English Flower Garden" for the best photograph of a garden or any of its contents, indoors or outdoors, sent to us in any one week. Second prize, Half a Guinea.

The Prize Winners this week are: 1, Miss Mabel Gaisford, The Grove, Dunboyne, for Snowdrops growing round the bole of a Beech tree; 2, Miss Tait, St. Madoes, Perth, N. B., for Trillium grandiflorum.

PLANTS AND FLOWERS.

INDOOR PLANTS.

HYMENOCALLIS.

In the accompanying illustration will be recognized an old occupant of our stoves, long known under the name of *Pancratium speciosum*, but now included under *Hymenocallis*, to which all the other plants generally grown as *Pancratiums*, with two exceptions, belong. These two are the hardy *Pancratium illyricum* and *P. maritimum*. *P. illyricum* is the only really hardy kind, growing from 1 foot to 2 feet high, and bearing in the summer umbels of pure white fragrant flowers. It does well in a warm, exposed border of sandy loam, well drained, the bulbs protected by litter in the winter. It is easily increased by offsets.

HYMENOCALLIS SPECIOSA (here figured) was introduced from the West Indies in 1759. It is handsome at all seasons, for the green massive foliage is retained all the year round, and when the plant is bearing its head of pure white sweetly-scented flowers it will commend itself to everyone.

H. MACROSTACHYANA.—In this the leaves are

in pots, for the simple reason that between October and February it virtually needs no water at all, but during the growing season it may be liberally supplied with moisture. It delights in a temperature ranging from 65 degs. to 75 degs., and is an ornament to any warm-house. Although a stove plant, it may be grown in a warm-house. The compost suited to its requirements should be loam and sand to two parts of peat.—W. F.

TREE-PEONIES FOR THE HOUSE.

In the Paris district, more especially the North of France, the flowering of Tree-Peonies is frequently endangered by late frosts, so that it becomes necessary to give them the shelter of a wall, and to protect them with sail-cloths. By advancing cultivation also, we can make sure of having blooms in February and March—that is to say, a month or two before the normal period. This plan, which is very simple and easy, consists in growing the plants in pots one year in advance. In November the plants are put under glass, then in February removed to a greenhouse heated from 40 degs. to 45 degs., taking care to give them the benefit of full light, and to place them as close to

should either be potted, or it may be they may not want more pot-room. Then it is best to cut the growth in, if necessary, surfacing with good soil. All forcing shrubs and hardy plants are much benefited by being plunged to the top of the pots through the summer, standing in an open position where the wood can ripen well. Some prefer planting such things out, but I have never seen any good results from this treatment, unless they are to remain out for two or more years. I much prefer all things for forcing being grown in pots, especially for early forcing. You can never rely on things taken up from the open ground flowering satisfactorily. This year I have a fine lot of Persian Lilac. The plants have been in pots for years. During the last two years they have been plunged in ashes and stood in a sunny spot. When I come to take them up they have an enormous amount of roots gone out of the pots. I stand these in half paraffin-casks to force, and they are beautiful. Deutzias I have in the same way, and they, too, flower well. Many people purchase vigorous things from the open ground late in autumn, potting and forcing them. Far better obtain half the number of such as have been grown in pots for one or more years. This was brought to my notice last autumn when looking over a large nursery near London. It was just at the time the imported stuff was coming in. I saw a large number of big cases full of Deutzias in pots, with shoots 3 feet long, and the plants in 8-inch pots. These were grown and imported in this way.
J. CROOK.

RHODODENDRON VEITCHIANUM.

This is one of the best cold greenhouse plants for spring blooming. I am aware many object to it on account of the straggling habit, but when in the hands of careful growers the leggy habit is not so apparent, as by a careful use of the knife and tying in some of the strongest growth in the early stages a nice specimen can be had. To amateurs and others who appreciate a good sweet-scented cold greenhouse plant I would thoroughly recommend the one named above. This is a free-growing kind and a profuse bloomer. It is about fifty years since it was first introduced. In large conservatories, winter gardens, etc., where it can be planted out, it is quite at home, and when associated with Tree-Ferns, Palms, Camellias, and things of this nature, it is charming. Here it can be allowed to grow at will, and, being associated with other large plants, the habit is not so much noticed. When in bloom, the large mass of white, sweet-scented flowers fills the air with their perfume, and when cut in large sprays, using them in large vases with some light greenery, they are admired by everyone. It is not overdone who can plant it out. It can be grown most satisfactorily in a pot of any size, and may be bloomed in a pot from 6 inches upward. This is just the plant for amateurs, seeing it is not prone to insect attacks, is not a rapid grower, and does not need a lot of attention or frequent potting. It can be placed in the open during summer, and if plunged in ashes, etc., so much the better.

When potting, use a peaty soil, with a little fibrous loam, and enough sand to keep it open, potting very firmly, and giving abundance of water when growing. When in large pots it will remain healthy for a number of years in the same pot if given a little artificial manure when growing. I have a plant of *R. Veitchianum* now in the drawing-room in an 8-inch pot with fifty trusses of bloom open at one time.
J. CROOK.

NOTES AND REPLIES.

Clematis indivisa after flowering.—Please inform me how *Clematis indivisa lobata* should be treated after flowering? I have two plants which have just finished flowering—one in a pot, the other planted out in greenhouse border.—THOMAS CLARE.

[What pruning is necessary should be done immediately the plant is out of bloom, and never during its period of growth. If anything at such times is really found necessary in this way, it should merely be a thinning process where the shoots are too thick, removing those that are the least likely to produce flowers later on.]

Rhynchospermum jasminoides.—This old-fashioned greenhouse climber is by no means to be despised, its fragrance being quite sufficient to recommend it. At one time it

Hymenocallis speciosa. From a photograph sent by Mr. F. Parkins, Pepper Arden, Northallerton.

longer and narrower than in *H. speciosa*, the flowers being easily distinguished by the large, funnel-shaped cup. It is a good garden plant, and its flowering is not limited to any particular season of the year.

H. CARRIEA has long, rather thin leaves, and flowers after the manner of, but less showy than those of *H. speciosa*.

H. LITTORALIS is in the same way, but with longer flowers and very narrow segments.

H. HARRISIANA.—This does well in the greenhouse. Apart from the fact that it is hardier, it also differs from the other species in being deciduous.

H. GUIANENSIS has the long, drooping segments of the flower spirally twisted, thus rendering it very striking.

CULTURE.—The culture of the *Hymenocallis* is not by any means difficult, and some of them, such as *H. speciosa*, will stand in the same pots for many years and flower well. Good turfy loam, lightened as may be necessary with peat or leaf-mould and sand, will grow them well, while liquid-manure when the pots are full of roots is also beneficial.

Gloriosa superba.—One of the showiest of warm greenhouse climbers is this bulbous plant, that at present is in a dormant state, but may soon be started into growth. It bears quaint and striking flowers, at first yellow, but gradually changing to red. It is best grown

the glass as possible. The amount of water given should be proportionate to their growth. In this way flowers as large and as handsome as those grown out-of-doors will be obtained, and at a season of the year when flowers are rare in greenhouses the effect will be remarkable. When the flowers are all gone, and there is no longer fear of frost, the plants should be transferred to a half-sheltered bed out-of-doors, left to rest there for two years, after which they can be put back into pots for forcing anew the third year. It will be found an easy matter to prepare for each year a certain number of plants for forcing. A compost of two-thirds loamy soil and one-third of well-rotted manure with some sand added is well suited to the cultivation of these plants in pots.

JULES RUDOLPH (*Revue Horticole*).

GROWING SHRUBS, ETC., IN POTS FOR FORCING.

It is an uncommon thing to see many useful hardy shrubs after they have gone out of flower turned out in the open to be chilled with frost and cold winds. All plants that have been forced should be given cool treatment under shelter till the growing spring days come. The next point to consider is whether these are likely to make growth enough to be useful under glass another year. If so, then they

used to be exhibited in almost all the leading collections of stove and greenhouse plants, and certainly well-grown and bloomed specimens added grace to the heavier and malformed subjects. For covering pillars or walls in cool conservatories and carriage courts the *Rhynchospermum* is well adapted, as when planted out in a mixture of fibrous loam and peat, leaf-mould and coarse sand, it quickly covers a large area, and if judiciously thinned out each season immediately after flowering, will annually bloom most profusely. This thinning out is imperative, otherwise lateral shoots accumulate until a sufficiency of light and sun-heat cannot penetrate to ripen up the wood. A fairly sunny position is necessary. Its chief insect enemy is brown scale, a dressing of some safe insecticide each winter being necessary to keep it free from the pest. It is seen to the best advantage if the shoots are allowed to hang down loosely in a natural manner and not tied in formally.

Some good French Pelargoniums.

—The kinds I am now thinking of are what are termed French and English spotted kinds. The show kinds have mostly plain edged blooms, but the French and English spotted have most frequently fringed blooms. Added to this they have large trusses and blooms, the petals overlap each other, and are of a most enduring nature. Another recommendation to them is that they are good growers and have a strong constitution. They are best grown in moderately small pots, and, when potting, it is advisable to make the soil very firm. Manure-water should not be given till the pots are full of roots. Many lovers of these are shy of growing them, as they are liable to be attacked by green-fly. This is easily kept down if the plants are dewed over once a week with a fine sprayed syringe and some wash. I use Abol insecticide, as it is easily applied and cheap. Since doing this I have not needed to fumigate them. The following are very fine kinds, and enough for anyone to grow: Bred's White, Digby Grand, Dr. Masters, Duchess of Bedford, Edward Perkins, Hayes Crimson, Mme. Thibaut, Perle Blanche, Triomphe de St. Maude, Volonte Nationale, and Kingstoa Beauty.—J. CROOK.

Maiden's Wreath (*Fraocaa ramosa*).—

An old but valuable plant for our greenhouses, and when well grown at its best during July and early August. It has proved hardy in the west of England, but is not a success out-of-doors by any means. This is the time to sow seed to have large plants to flower next year, and as it is very minute, an even surface is requisite or failure will surely follow. Pans are the best to sow in, and these should be nearly filled with principally loam and leaf-soil, with plenty of sand. The soil, if at all dry, should be watered with a fine rose a few hours previous to sowing the seed. A thin sprinkling of fine sand after is preferable to soil; then cover the pan with a sheet of glass and place out-of-doors or in a frame, and shade until the seed has germinated, when stand near the glass, and prick off into pans or boxes when quite small, and afford water and shade until the seedlings make a fresh start. When ready for removal place into 4-inch pots, using good loam, one quarter leaf-soil, a 6-inch potful of bone-meal to every bushel of soil, and a little sand. Shift into 6-inch or 7-inch pots before the plants get pot-bound, standing them out-of-doors after the first potting. Protection from frost during winter is necessary, and towards the middle of May place outside, and see they do not suffer from drought. Old plants may also be divided in autumn, securing a bit of root with each offset. Keep fairly close for a few weeks, when treat as for seedlings, potting on as the plants become fit in spring. It is commonly known by the name of Bridal Wreath. The long, branching spikes are useful for cutting and last well in water.—I. M. B.

Begonia in bloom at Christmas.—At Christmas I saw in shops pots of a charming small-flowered pink Begonia in full bloom. In order to flower them thus in winter, when ought the dry bulbs to be purchased, and would the ordinary bulb treatment do—viz., starting them in a shady border in September, and putting the pots in a sunny parlour window at end of October? And which kinds would be suitable?—BELGIAN READER.

[The culture of the *Gloire de Lorraine* Begonia, which we are supposing is the one you have seen, is not at all exacting, the

principal difficulty being to obtain good cuttings in the spring, as it is useless to propagate from cuttings of the flowering-shoots, as they will not branch out, but continue to produce blossoms. The best cuttings are obtained from old plants that have done flowering, and if they are shortened back about February they will in time push out young shoots from the base. When these shoots are from 1½ inches to 2 inches long they make the best of cuttings, particularly if taken off close to the old stem. Put into well-drained pots of light sandy soil, pressed down only moderately firm, they will soon root if placed in a close propagating-case in a gentle heat. Care must be taken not to overwater, otherwise the cuttings are liable to damp off. Directly they are rooted more air must be given, and though the young plants succeed best in a gentle heat early in the year, later on they may be grown in a greenhouse or frame, though when the nights get cold in autumn a little heat is again necessary. A mixture of loam and leaf-mould, with a sprinkling of sand, will suit this Begonia, but when the pots get full of roots an occasional dose of liquid-manure is of great service.]

Plants with fine foliage.—Will you kindly name about a dozen plants with beautiful foliage (greenhouse)?—T. R. R.

[The following will all thrive in a greenhouse: *Aralia Sieboldii*, a stout-growing shrub, with large, leathery, Fig-like leaves. *Araucaria excelsa* is a very symmetrical growing member of the Fir family that is largely grown for decoration. *Asparagus plumosus nanus* is a charming delicate-looking plant, often called the Asparagus Fern. *Asparagus Sprengeri* is altogether more robust than the preceding, but equally beautiful. *Coprosma Baueriana variegata* is a freely-branched evergreen bush, with very shiny leaves, in colour bright green, with a broad margin of creamy-white. *Cordylina australis*, the Lily-tree of New Zealand, is, when young, very ornamental, the long, Grass-like leaves being borne on quite a woody stem. *Ernya latifolia variegata* is a Camellia-like shrub, whose leaves are marked with green, yellow, and pink, in varying proportions. *Ficus elastica* is the well-known and popular India-rubber-plant. *Grevillea robusta* is an erect-growing shrub, with deep green Fern-like leaves. *Ophiopogon spicatum variegatum* and *O. Jaburum variegatum* form dense tufts of Grass-like foliage, firm in texture, with white and yellow variegation respectively. *Phormium Veitchii* forms a tuft of sword-like leaves striped with yellow, and *Colensoi* with white. They belong to the New Zealand Flax family. *Yucca aloifolia variegata* is one of the best of the greenhouse Yuccas, leaves variegated with yellow. Besides the above, the different varieties of *Coleus* form very attractive specimens for the greenhouse during the summer months. We have not included any Ferns, though most of them come under the heading of beautiful foliage plants. A good dozen of easy culture are: *Adiantum cuneatum*, *Adiantum decorum*, *Asplenium bulbiferum*, *Davallia bullata*, *Lastrea aristata variegata*, *Oncidium japonicum*, *Polypodium aureum*, *Pteris argyrea*, *Pteris cretica aloifolia*, *Pteris serrulata cristata*, *Pteris serrulata major*, *Pteris tremula*, *Pteris Wimsettii*. The hardest Palms are: *Chamaerops excelsa*, *C. Fortunei*, and *C. humilis*, *Corypha australis*, *Kentia Belmoreana*, *K. Forsteriana*, *Latania borbonica*, and *Rhapis flabelliformis*.]

Seedling Cyclamens.—Please tell me what I should do with over a dozen pots of seedling (pericum) Cyclamens which show no signs of flowering? They were sown in February, 1901, but I was not so fortunate as your correspondent "R. B. Rogers." The little plants are in 60-pots, full of leaf, free from any disease, and quite healthy, but I fancy they were grown too slowly at first, or that the temperature of the greenhouse varied too much. I had the pots plunged in fibre in a wooden box standing near the hot-water-pipes. I now want to clear the greenhouse, and would like to know what to do with my Cyclamens, so that I may have flowers next autumn?—R. K. R.

[Place your Cyclamens on a bed of ashes in a cold-frame, so situated that the mid-day sun does not shine directly on it. Continue to water carefully as before, till in another month or so many of the leaves will in all probability die off, when the plants must be kept somewhat drier, but on no account should they be pashed up at any time. Then, early in July, repot your plants, at the same time removing as much of the old soil as can be done without injuring the roots. A suitable compost for the Cyclamens is two-thirds good fibrous loam to

one-third leaf-mould, and a liberal sprinkling of silver-sand. Take care that the pots are clean and well drained, and above all avoid over-potting. After this, watering must be very carefully done, being particularly careful against an excess of moisture, while an occasional light syringing two or three times a day will be very beneficial. The plants will need to be shaded from the direct rays of the sun. If these directions are carried out the plants will by autumn have formed neat specimens that will furnish a good display in the greenhouse later on. You need not reproach yourself because your Cyclamens have not yet flowered, for very few attain a measure of success equal to that referred to, unless the plants are grown in quantity and an entire house given up to their cultivation, so that their requirements can be exactly followed, which is not possible in a structure containing a miscellaneous collection of plants.]

Hydrangeas.—Young plants of Hydrangeas that were propagated last year should now receive special attention, encouraging the growth in every possible way, as few plants are more fitted for window-decoration when one takes into consideration the long time they remain in bloom. For pot culture it is a favourite plan to restrict them to one or two beads of flowers, and they grow best in a compost of sandy turf and leaf-mould. Hydrangeas are thirsty subjects, and inattention to plants in pots in this respect is at the expense of blossoms. Old plants in pots often benefit by an application now of a stimulant. They are most useful for a cool greenhouse, corridors, and in some places where it is customary to "stand out" plants on lawns during the summer. Hydrangeas are easily propagated from cuttings, which should be procured from plants that have stood out-of-doors in the sun-lit, and so have thoroughly ripened their wood. Indeed, it is futile to attempt to propagate from any but ripened wood. August is the time for this, selecting sturdy shoots, each having, if possible, three pairs of leaves, cutting away the first pair and inserting them firmly in separate pots of loam in which sand has been largely incorporated, placing them in a frame or under a bell-glass, and keeping them close until rooting has begun. Just keeping them away from frost is sufficient during the winter, as they will probably lose their foliage. Plants treated in this way will be going ahead now, and will make nice specimens suitable for a 6-inch pot.—W. F. D.

Celsia cretica in pots.—This, allied to the *Verbascum*, is a very showy annual for the greenhouse. Seeds sown now in heat will soon germinate, and as soon as fit to handle prick off the seedlings into pots or pans of light soil 2 inches apart, keeping near the glass in a little heat, and shade for a day or two. In three or four weeks pot them off singly into 5-inch pots or place three in a 7-inch pot, using principally loam, with a little leaf-soil and sand, potting firmly and placing in a cold-frame. If shaded, with a dewing overhead twice a day, the plants soon recover and grow away strongly, each one carrying a central spike 18 inches to 24 inches long, closely studded with pretty yellow flowers. I have tried pinching of the shoots, but the flower-spikes are much more slender when this is done. Another sowing made at the end of May would supply a nice batch of plants for late autumn work, when, if given a little fire-heat, such as afforded Tree Carrotons, they will continue to expand their flowers for some time. The plants may be cut down after passing out of bloom and repotted when nicely on the move, when they will soon come into flower again. They can also be increased by cuttings, but seedlings make much the strongest and also healthiest plants, and are much the best when given fairly cool treatment. No insect appears to trouble this *Celsia*, but towards the dark, dull days of November it is liable to turn black in the stem and decay if too much moisture is given or if the plants are crowded among others.—J. M. B.

As many of the most interesting notes and articles in "GARDENING" from the very beginning have come from its readers, we offer each week a copy of the latest edition of either "STOVE AND GREENHOUSE PLANTS," or "THE ENGLISH FLOWER GARDEN." To the sender of the name, address, or interesting letter or short article published in the current week's issue, which will be marked thus "I."

ROSES.

ROSES ON ARCHES.

Now that the so-called Garden Roses—a term that is applied to all those that do not produce show blooms—have gained such a hold on popular estimation their numbers are yearly on the increase, and amateurs often experience a difficulty in making a selection for their purpose out of the wealth of Polyantha Roses, Ayrshire Roses, Evergreen Roses, Provence Roses, Moss Roses, Hybrid Chinas, Alba, Musk, Briers Penzance and Austrian, Damask, Wichuriana, Rugosa, &c., that fill nearly one half of the Rose catalogues of to-day. Arches, pergolas, pillars, and trellises are among the most favoured methods of displaying the beauties of the Garden Rose, and something answering one of these descriptions is generally to be found even in the smallest of flower plots. The long straight walk, spanned at intervals of 4 feet or so by iron arches, covered from end to end in the summer with a wealth of Rose-blossom, is a feature in any garden. Much has been

over trellises or arbours. Many exhaustive articles have been printed in the pages of GARDENING ILLUSTRATED during the past year or so on the best Roses of the several sections for decorative work in the garden, whether as climbers, trailers, or bushes, and any amateur anxious for information on this point can easily obtain it by turning to the back numbers.

S. W. F.

— It would be difficult to overpraise the Rose in all arrangements of climbing plants. Many of the more vigorous wild Roses of the northern world are naturally almost climbing plants, and some of them are seen 20 feet high or so among trees. In gardens many varieties might be mentioned which in past years were a great source of beauty and produced a fine effect when well used, but in our own time and within the past generation or two since the raising of Gloire de Dijon a noble series of climbing Roses quite distinct from the old climbing kinds has been raised, these being among the most precious flowers that have ever adorned the Rose-garden. The old climbers and Garland Roses were almost too

autumnal-flowering single, of which our collections are at present very much in need. Many charming Roses of this description could readily be obtained by anyone having means of procuring Tea Rose seed from the continent, where it ripens so readily. Sow the seed in January in a cold-frame facing south. Remove the bottom soil and put in a good layer of corks, then a few inches of soil, sifted loam, and a liberal sprinkling of sand. Draw very shallow drills and sow the seed, covering it very slightly. Previous to sowing, the soil should be watered, but not afterwards until seedlings appear. When this occurs in April, paint the glass with some whitewash and give plenty of air. As soon as the seedlings make their third leaf prick them off carefully into thumb-pots, using a compost of sifted loam two parts and sand one part. Plunge the pots into a cold-frame with glass slightly shaded for a few days, then expose to full sun, and afford as much air as possible. In June the plants may be planted out in a sheltered border, where they can be protected from birds and insect pests. Some of the little plants may flower the first year,

Roses on arches. From a photograph by F. Mason Good, Winchfield.

written against the employment of iron arches, but where these consist of simple rods bent into arches and so stayed together that they are secure against the effects of gales, they are so speedily covered by foliage and flower as to be entirely lost to sight. Another merit possessed by such arches is that being so slight they throw no shade, and, if not set too close together, the sunlight filtering through the loosely-trained growths permits Roses to form and expand beneath the arches as well as above them. In the accompanying illustration the growth has attained such thickness as to throw a dense shade on the under side of the arch, where the flowers are few or lacking in comparison to their countless numbers at the sides and top of the arch, where they are exposed to the full sunlight. A judicious thinning-out of the old wood, in order to allow the sun's rays to penetrate the foliage, is often advisable with arches and pergolas. Where Roses are allowed to grow in masses at their own sweet will pruning is unnecessary, since the outer surface of the bloom-studded bushes is all that meets the eye, a remark which applies with equal effect to Roses grown on pillars or

vigorous for the garden and did not last long enough in flower to justify their getting a place there, but now, with the fine climbing Tea Roses we have from the southern parts of these islands, we may count on bloom for many months. In these Roses we have the most precious of all ornaments for walls of houses, trellis-work, and pergolas. Apart from these homo-raised Roses we have some Wild Roses of the greatest value in warm districts and good soils, particularly the Indian R. Brunonis, and R. polyantha of Japan. These Wild Roses will usually be best in places where they can be left alone. No good can follow giving choice garden ground to such as these, which are even more vigorous than our own wild Dog Rose.

A CHARMING SINGLE ROSE.

A very lovely little Rose is Miss Willmott. It is perfectly single, the petals of the colour of L'Heal, from which presumably it is a seedling, although I do not detect the sweet fragrance of the latter. This novelty is dwarf in habit and should prove very useful as an

but it would be advisable to pinch off the buds in order to better prepare them to stand the winter. As our winters are so uncertain, a frame, on which a light could rest, should be placed over the plants. This, together with placing a handful of burnt earth around each plant, should bring them safely through. Only those who have raised seedlings can form any idea of the fascination which the work brings, and there is always a chance of obtaining one or more good double kinds among the number, although the majority will be single. The main point is to save the seed from the lovely tinted Teas that are now so abundant, and even the Chinas, such as Mme. F. Resal and Queen Mab, should yield some pretty offspring. Beryl is little more than a single Tea, but what a lovely colour; and Irish Beauty, Irish Modesty, and Irish Glory are also good.

ROSA.

Pruning Rose Marechal Niel.—I have in a small greenhouse a Marechal Niel Rose which has flowered well. There are still a few buds, but when these are over I should like to know how to treat the plant, as it is beginning to get rather crowded. Should I cut out all the old wood, leaving only those rods which were

thrown out from the root last summer, and which have not yet flowered? There are several of these, and the lateral growths from them during next summer should, I think, fill the space I can spare. Any hints will be gratefully received by—LOVER OF GARDENING.

[As much wood as possible that has been produced this summer should be retained, and spread out as much as possible, in order that it may get well ripened, as this gives the best blossoms. As a rule, it is preferable to do such pruning as is necessary to this Rose soon after its spring blossoming, then it has a long season to mature the growths which follow, and we rather favour a practice now much adopted of pruning rather severely every alternate year.]

OUTDOOR PLANTS.

HARDY PLANTS FOR MID-SEASON FLOWERING.

IN continuation of the article which appeared on page 43, mentioning some of the best hardy flowers for the spring months, those plants which provide the most ornamental effect during June and July, when the garden picture attains its brightest and most varied colouring, are now to be considered. Many of the subjects alluded to in the former article retain their beauty through a part or the whole of the season now under review, noteworthy examples being: *Achillea ptarmica* fl. pl., *The Pearl*, *Aquilegia*, both species and hybrids; *Erigeron speciosus* and *E. marianus*, *Geum*, *Day Lilies* (*Hemerocallis*), *Incarvillea Delavayi*, Spanish and German Irises, *Lily of the Valley*, *Paeonies*, both tree and herbaceous; *Oriental Poppies*, and *The Prophet's Flower* (*Arnica montana*). In the wilder portions of the garden, and especially in the neighbourhood of water, the Monkshood (*Aconitum napellus*) has a handsome appearance with its tall blue spires, and the *Aconitum*, of which the best is *A. latifolium*, is the personification of noble form when allowed sufficient space to express its natural contour, plants in good soil often throwing up towering flower spikes to a height of 7 feet or 8 feet above their shining, gracefully curving leaves. *Acaena microphylla* is interesting when covering rough stonework with its countless rosy-spiked blossoms, and *Agathaea celestis*, though not hardy except in the extreme south-west, is a pretty sight when bearing its pale blue flowers. *Agapanthus umbellatus* and its white form are particularly handsome plants in sheltered and well-drained gardens in the south-west, where they form giant clumps, sometimes as much as 15 feet in circumference, and bear their great blue and white flower umbels by dozens during the summer months. In none but exceptionally mild localities, however, can this plant be recommended for permanent planting out, but where this is inadvisable a fine show may be made by keeping the specimens in large pots or tubs under glass shelter during the winter and standing out in the summer. *Anonathes cruenta* is a pretty little liliaceous plant bearing spikes of red flowers about 6 inches in height, and providing a pretty picture in the border or rock-garden. It increases rapidly from self-sown seeds. *Hollyhocks* (*Althaea*) are stately flowers that add much to the beauty of any border. They are, unfortunately, a prey to a disease that destroys their foliage, known as the *Hollyhock fungus*, but this has fortunately been less virulent during the past few seasons. Seedlings possess a more vigorous constitution than plants raised from cuttings, and, therefore, enjoy a greater immunity from disease. Semi-double varieties are much to be preferred to the forms whose flowers are a mass of crowded petals. The single yellow *Althaea ficifolia* is also a charming plant, well worthy of a place in the border.

Alstromerius should be grown in every garden, for there are few more ornamental flowers than the hybrid *A. chilensis*, whose tints range in colour from cream to crimson, and which, when once established, increases year by year. The tubers should be planted at a depth of 6 inches, and though they will endure 20 degs. of frost it is safer to provide them with a winter mulch. *A. aurantiaca* is a handsome orange-flowered species; and *A. pelegina* and *A. p. alba* are two lovely flowers, but too delicate for open air culture in the majority of gardens. The large form of

St. Brauo's Lily (*Anthericum Liliastrum majus*) is a valuable plant with fine white flowers, and is far superior to the type or to any of the varieties of *St. Bernard's Lily* (*A. Liliago*). A fine, large-flowered form of *Anchusa italica* has lately been distributed, which is a great advance upon the type, and which, from its lengthened flowering period, makes an excellent back-row plant. The *Sea Pinks* (*Armeria*) in their many species and varieties are invaluable for edgings, and may be cultivated with a minimum of trouble; while the handsome *Plumo Poppy* (*Bocconia cordata*) is a striking object at the back of the border when rearing aloft its tall heads of ivory-white inflorescence. The *Calochorti*, though extremely beautiful, are not everybody's flowers. The hardiest and one of the handsomest is *C. venustum Vesta*. A warm situation and porous soil are imperative. Of tall-growing, summer-flowering *Campannulas* the following are good: *C. grandis* and *C. g. alba*, *C. lactiflora* and *C. l. alba*, *C. latifolia* and *C. latifolia alba*, which is also excellent for the wild garden, the *Chimney Campanula* (*C. pyramidalis*) and varieties of *C. persicifolia*, of which the best are *Backhouse's variety* and *C. p. Mochreimi*. Of lower-growing *Campannulas*, *C. carpatia* and its forms *C. e. turbanata* and *C. e. polyvarium*, *C. caespitosa*, *C. isophylla*, and *C. l. alba* are all good. *Cyananthus umbellata* is a showy little plant with brilliant magenta-crimson flowers, and *Callirhoe involucrata* and *C. Papaver* are two charming plants, whose crimson and purplish blossoms are seen to best effect when trailing over a rock face.

Cornations are at their best in July, and should find a place in every garden. Self-colours are the best for effect. The yellow-flowered *Cretan Mullein* (*Celsia cretica*) is an ornamental plant, and *Chelone* (*Pentstemon barbata*), with its tall spikes of drooping scarlet blooms, is bright and graceful, while *Chrysogonum virginianum* bears its yellow flowers through many weeks. *Cimicifuga racemosa* is too uncommon in gardens, but its long, pendent, white racemes render it most decorative when in bloom. It grows to a height of 6 feet, and is of the easiest possible culture. *Conopsis ovata* bears French grey, bell-shaped flowers, marked in the interior with a purple ring, and both the white-flowered *Convolvulus Cuesum* and the blue-flowered *C. mauritanicus* are most desirable plants, while for lengthened brilliance nothing can excel the golden-flowered *Coreopsis grandiflora*. *Delphiniums*, ranging in colour from palest blue to purple, are one of the most striking features of the summer garden. They require deep and rich soil to attain their finest proportions. The old *D. Belladonna* is not yet surpassed in its delightful pale blue. White varieties have of late been introduced, and we may look for great improvements in this direction in the near future. The scarlet-flowered *D. nudicaule* is attractive when well grown, as it can be, in porous soil. Of Pinks, none can rival in colour *Dianthus Napoleon III.* and *D. Atkinsoni*. Unfortunately their freedom of flowering often causes their death, so that it is well to keep some plants denuded of flower, in order that they may blossom the following season. The common white Pink and the improved varieties *Mrs. Sinkins* and *Her Majesty* are invaluable for their fragrance, which is unrivalled in the long June twilights. *Dictamnus Fraxinella* and its white form make fine border plants if allowed to remain undisturbed for a few years, and *Desmodium penduliflorum* (*Lespedeza bicolor*) is a pretty picture when its shoots are thickly set with drooping carmine flowers.

Globe Thistles and *Sea Hollies*, from their distinct colouring and striking form, are valuable in the border. Of the first, *Echinops Ritro* is a good species, while of the second, *Eryngium amethystinum*, which, by the way, is seldom to be met with true to name, *E. Oliverianum*, and *E. Bourgati* are among the best, the metallic blue of the flower bracts being quite unique in the garden. The *Rocky Mountain Willow Herb* (*Epilobium obcordatum*) is a beautiful rock plant, and the white variety of the common *Willow Herb* (*E. angustifolium*) is worth growing. The *Plantain Lilies* (*Funkia*) are especially desirable on account of their fine foliage, but *F. grandiflora* bears large white blossoms, and is in addition a handsome flowering plant. *Gaillardia* and

Gazania are amongst the brightest of our summer flowers, and for tall subjects, *Gallega officinalis* and its white form, the *Cape Hyacinth* (*Galtonia candicans*) and *Gaura Lindheimeri* are worthy of attention. Among *Geraniums* are many pleasing species, one of the most attractive being the white variety of *G. sanguineum*. *Oarbera Jamesoni* is a gem, bearing large, single Daisy-like flowers of a vivid orange. It is, however, difficult to establish, except in hot, dry soils, and resents excessive wet during the winter season. *Gypsophila paniculata*, with its billows of flower-lace, is indispensable in the border, and no plants can excel the *Sun Roses* (*Helianthemum*) for gorgeous summer effect over stone edgings. *Inula glandulosa*, with its wide-spread stars of deep orange, is a showy plant, and the tall Irises, *I. orientalis* or *ochroleuca*, *I. anrea*, and *I. Monnierii*, the first white and the others deep yellow, are most effective, as is *I. Kämpferi* in damp positions. *Jalovaca integrifolia* is a little-known plant, producing fragrant white flowers like a glorified *Nierera lergia*. The green-leaved *Lobelia cardinalis* commences to bloom in July some weeks in advance of *L. fulgens* and its varieties, and three *Mallows* are then at their best—namely, the white-flowered *M. moschata*, the reddish-pink *M. Munroana*, and *M. lateritia*, the last bearing exquisite flowers of pale salmon hue, marked with a carmine band in their interior. *Modiola geranioides* is another seldom-grown plant bearing bright rose-red flowers about an inch in diameter. *Libertia grandiflora*, with its flower-heads 3 feet or more in height, thickly set with white blossoms, is strikingly beautiful, and of the *Linums* the yellow *L. arborescens* and *L. flavum* and the blue *L. narbonense* are charming when in flower, and the deep blue of *Lithospermum prostratum* has a telling effect when draping a rock very luxuriantly. *Lupines*, blue and white, are almost as necessary as *Delphiniums*, and bright colour is provided by the scarlet *Lychnis chalcidonica* and *L. Haagena*, and by the rosy *L. Viscaria splendens*.

The *Bee Balm* or *Bergamot* (*Monarda didyma*) creates a fine effect with its crimson flower-heads when boldly massed, and the sweet-scented *Nicotiana affinis* and the more recently introduced *N. sylvestris* add beauty and fragrance to the garden. Many of the *Evening Primroses* are lovely flowers, especially the white (*E. marginata* and *E. speciosa*), and the yellow *E. frutescens* and *E. macrocarpa*. *Ornithogalum pyramidale* is a fine *Star of Bethlehem*, growing to a height of 3 feet, and *Ostrowskia magnifica* is a splendid plant, sometimes 6 feet high, and bearing numerous flowers 5 inches and more in diameter. There are purple-flowered and white-flowered forms of this plant, of which the latter is to be preferred. *Onosma tauricum* produces its tubular yellow flowers in profusion in a warm, well-drained site where *Pentstemon Scouleri* is smothered in its purple blossoms. Of the handsome *Herbaceous Phloxes* two of the best are the white *Mrs. E. H. Jenkins* and the glowing *Coquelicot*, *Aëna* being very similar to the latter. No washy, undecided colours should be grown. *Phygelius capensis*, with its drooping scarlet flowers, is both pretty and uncommon, and *Platycodon grandiflorum* and *P. Mariæi*, crowded with their large blossoms, are most attractive. *Jacob's Ladder* (*Polemoniumeruleum*) is an old-fashioned garden plant that is not without its charm, and, besides the glowing *Oriental Poppies* already noted, we have the *Island Poppies* in their colours of yellow, orange, and white, the apricot-buff *Papaver pilosum*, and the drooping yellow *Welsh Poppy* (*Meconopsis cambrica*). Many of the *Potentillas* have extremely beautiful flowers, and the *Pyrethrums* have of late years been so marvellously improved that the brightest colours are obtainable, both in single and double varieties. *Ranunculus pyrenaica* is best suited in a perpendicular chink in a shady rock, but it sometimes does well in a north border. *Ranunculus aconitifolius* fl. pl., which shares with *Saxifraga granulata* the title of *Fair Maids of France*, is a cottage garden favourite, as is the double *Sweet Rocket*, one of the most fragrant plants in existence, and one that should be in every garden. It requires yearly division and fresh soil, or will not retain that

abundant vigour that is necessary for it to produce its perfumed flower-heads to perfection. *Campanula Coulteri* is a lovely flower. The plant grows from 6 feet to 9 feet in height, and often bears hundreds of large, single, white flowers, quite 6 inches in diameter, with petals like white crepe, and a splendid boss of golden stamens, which possess a pleasing fragrance. The best results are obtained by cutting down the previous summer's growth as soon as the roots break from the base in the spring. The pale blue *Scabiosa caucasica* and its white variety are pretty flowers, and there is now an improved form of the first-named—*S. c. magnifica*—while the tall, pale yellow *S. clata* and *Telekia grandiflora* should be placed at the back of the border. *Sidalcea Listeri* is a beautiful plant, and is by far the best of its family. Two Coneflowers—the orange *Rudbeckia Newmanii* and the rose-crimson *R. purpurea*—are reliable border plants. *Tigridius* are now to be purchased at a cheap rate, and in warm soils will come to no harm if left over the winter in the open border. Scarlet, rose, yellow, and white varieties can be procured, which will give an indescribably

grand effect. Perennial Delphiniums should be provided with a bed at least 2 feet 6 inches in depth, the soil of which should be richly manured, while a mulch of well-rotted Mushroom-bed or hot-bed manure in the early summer will have a beneficial effect both in keeping the surface soil moist and in acting as a fertiliser. In dry weather copious supplies of water should be afforded and periodical waterings with weak liquid-manure will add greatly to their vigour. If treated in this manner Delphiniums, when at the zenith of their comeliness, will be the glory of the garden. In the innumerable varieties now in commerce every shade from palest blue to purple is represented, some having white eyes, some black, while in some the inner petals are rose-coloured. A large proportion of these have double flowers, but on the whole one cannot but conclude that the varieties with single or semi-double flowers are preferable both for distant effect and for closer inspection. Of late years a new departure in colour has been achieved, two white Delphiniums having been brought out by Messrs. Kelway and Son, namely *Beauty of Langport* and *Primrose*.

take up, arguing that frames can be better occupied with *Calceolarias*, etc., in winter, which are of service in a garden during the summer months, but if it is only for the fact that in the darkest days of winter, when all flowers are acceptable, their fragrant blooms may be gathered under the shelter of a frame, then the utilising of frames in this way is surely not a mistake. Those who have once had a good crop of, say, the Neapolitan Violets in the middle of January will scarcely object to the space they require, and as just now it is necessary to consider the treatment they need to ensure blossoms next winter, these noles may be of service to someone who is setting apart a frame for the first time for them. Now that Violets in frames have practically ceased flowering is the time to set about making use of the runners. In the first place, then, a piece of ground should be set apart for their reception, and into it should be dug manure partly decayed, as, for instance, manure from a Mushroom-bed or that which has stood in the garden for a few months. Some leaf-mould and sharp sand incorporated with the soil will help the plants. In selecting the site for Violets during the summer, one should bear in mind that a north or west aspect is the best, inasmuch as it is where partial coolness is experienced that the plants become vigorous, and although a south position is undoubtedly the quarter where one should place them during the winter, too much sun is likely to be harmful to young plants; at any rate, this has been my experience. One cannot always be watering Violets—a necessity if during the next few months a south aspect is selected for them. To be successful with Violets, one must not forget, too, when planting the runners to first make the bed firm, either beating it with a spade or trampling down the soil, then dibbling the runners in. Too much attention cannot be given to this point, as if the bed is simply dug over and the runners planted therein useless growth ensues, but given a firm root-run at the outset plump crowns will result. I do not wish to infer that because planting is not done on a south border watering will not be needed; on the contrary, needful attention must be given in this respect, but by choosing a somewhat cooler position moisture will not be needed to such an extent. Early in October frames should be prepared for their reception, and the warmest position the garden affords should be selected so as to have the earliest blossoms. The nearer the glass Violets can be planted the better, as if too far away from it damping off often occurs; but the need for ventilation of the frames will be patent to the grower. Many cultivators of Violets object to their being removed in the autumn for fear of the roots being disturbed, and grow them on in beds, so that all one has to do is to drop the frame over them. There is a deal to be said in favour of this, as if care is not exercised in digging up the clumps their progress is retarded for a time, but a spadeful of soil taken with each clump will minimise any root disturbance. I have, however, seen Violets that have been grown on raised beds on a south border expressly for convenience of frames, but they have not compared very favourably with others grown under cooler conditions. For winter quarters there is nothing for Violets like a south border—one, if possible, shielded by a wall at the back, as there from November to April one may always cut blossoms. A market grower once told me that he only covered his beds with frames in severe weather and times of continued wet, and as a winter crop they paid well, sending as he does to market from November onwards, but he lives in the west of England. WOODBASTWICK.

Delphiniums in the garden. From a photograph sent by Mr. H. H. Powell Cotton, The Manor House, Westerham, Kent.

brilliant effect when in flower. Globe-flowers (*Trollius*) succeed admirably in a damp position. Orange Globe is a magnificent variety of recent introduction. Lilies, which are one of the features of the summer garden, must be treated separately. S. W. F.

DELPHINIUMS IN THE GARDEN.

Of the numerous noble perennial flowers that add to brightening the summer garden few can rival and none excel the Larkspurs. The annual species are pretty, but they lack the decorative value of the perennials, which, when well grown, often reach a height of 9 feet and more, and bear aloft as many as seventy towering flower-spikes. To attain such freedom of flowering and dimensions, however, the needs of the plants must be carefully anticipated and provided for. It is useless to expect them to display their beauty to the fullest possible extent when relegated to a bed of poor, shallow soil, where they lack the needed sustenance and where their roots are parched by the summer droughts. In such a site they will not do, indeed they will very probably compare favourably with other inhabitants of the border in these adverse circumstances, but they will give but little idea of their capabilities for

Both have white petals, the former having a pale buff eye and the latter a primrose eye; both are beautiful flowers. The old favorite *Belladonna*, though by no means a strong grower, is, with its clear azure-blue flowers, one of the most delightful of the whole race.

Delphiniums are best divided and transplanted in spring, when they have made about 3 inches of growth. The clumps should be lifted and divided with a sharp knife, and the sections planted in rich, porous soil, a little lower than was the case in the site from which they were lifted. Should dry weather intervene care must be taken that they are not allowed to lack moisture during the time that they are becoming established in the fresh soil. S. W. F.

VIOLETS AFTER FLOWERING.

THESE, the sweetest of winter and early spring flowers, should be grown by all who have cold-frames. In the south-west of England Violets may be, and are, cultivated and bloomed in the open throughout the winter with much success, but in colder localities one has to take into consideration the rigours of winter, and therefore a garden frame is essential to them. So many people, it is true, begrudge the room Violets

grower. Many cultivators of Violets object to their being removed in the autumn for fear of the roots being disturbed, and grow them on in beds, so that all one has to do is to drop the frame over them. There is a deal to be said in favour of this, as if care is not exercised in digging up the clumps their progress is retarded for a time, but a spadeful of soil taken with each clump will minimise any root disturbance. I have, however, seen Violets that have been grown on raised beds on a south border expressly for convenience of frames, but they have not compared very favourably with others grown under cooler conditions. For winter quarters there is nothing for Violets like a south border—one, if possible, shielded by a wall at the back, as there from November to April one may always cut blossoms. A market grower once told me that he only covered his beds with frames in severe weather and times of continued wet, and as a winter crop they paid well, sending as he does to market from November onwards, but he lives in the west of England. WOODBASTWICK.

Hops.—The beauty of a field of Hops when in bloom is admitted on all hands, but few think of them as being suitable for growing in gardens. Have you any wire arches where you

have found it difficult to grow other climbers? Then try Hops. Have you a damp corner in your garden where other things will scarcely exist, or walls want covering quickly? Then give Hops a trial. You will find they will soon accommodate themselves to almost any position. Plant them now if you desire their beauty this season. Galvanised wire is a poor medium for many plants to climb, but Hops will thrive on it.—W. F. D.

WALLFLOWERS.

No spring blossoms are so welcome as Wallflowers, but the culture of them is often attended with disappointment, more especially after a hard winter, the beds where they have been planted presenting a "scrappy" appearance. This obtains particularly in town gardens where the walls and fences surrounding them seem to afford but little shelter, and some friends I know who used to grow them every year have now given them up, because of being able to rear so very few that are worth anything. Whilst some of the plants in my own garden died away owing to the severe frosts we experienced in January and February, plants I had in another garden a short distance away from home, quite unprotected, and practically in the country, have all turned out well. For one reason I attribute the success of the latter plants, which, at the time I write, are sturdily and full of buds, to the early sowing of the seed—viz., end of April, 1901, whereas those grown in the home garden were sown a little later. Many defer sowing the seed until they have finished their summer bedding, which is frequently not until the end of June, and the consequence is, instead of being good-sized, well-established plants by November, they are not nearly so large as they ought to be. Undoubtedly the better plan is to sow the seed not later than May, as the plants then, with the whole of the summer before them, have ample time to develop, and consequently are able much easier to stand the winter. Admirers of Wallflowers are waking up to the knowledge that there are other varieties than the Blood Red. Do not suppose that I have no liking for this old sort—I would not be without it on any account. The sorts I have under cultivation comprise: Blood Red; Harbinger (brown); Faerie Queen (lemon); Vulcan (purple); Eastern Queen (apricot), and Golden King (golden-yellow). By doing this I get a display rather longer than usual where only two sorts are grown, and when planted in beds the effect is very pretty in May.

I doubt whether it is always the wisest plan to plant Wallflowers, in the place where they are to bloom, as late as November, a practice which many people follow, with results not always satisfactory. I have come to the conclusion that, provided the plants are not unduly crowded in the seed-bed, it is advisable to leave some of them until spring, and then do the necessary transplanting. An illustration as to the undesirability of removing quite young plants late in the autumn came under my notice last November, when in passing through some gardens I noticed men busy at work "dibbling" in Wallflowers that had evidently been drawn out of the beds, for there was little soil attached to the roots, and the plants themselves were not half the size they should have been. No wonder that they could not withstand the sharp frosts we had in February, and that since then they have nearly all been pulled up and thrown away. I think, too, that sufficient notice is not paid to the state of the ground when Wallflowers are planted in the autumn; this should, of course, be well dug, and manured if needed, for in an impoverished soil one cannot expect success, yet it is strange that those who grow them often overlook their requirements in this respect. I have no objection to a mulching of manure during the winter round my beds of Wallflowers, as there is no question many tide over the worst part of the year when this is done. It behoves all who desire plants for blooming another spring to be a little beforehand with the sowing of the seed, for if it should turn out that the seedlings are growing too quickly, a pinching of the leader will induce a bushy habit, which even in a Wallflower is often desirable.

WOODBRIDGE.

WHAT TO GROW ON NORTH BORDERS.

VERY frequently enquiries are made as to what plants will grow and succeed on a north border. Some who read these notes, and whose experience of growing plants on north borders has been more of failure than otherwise, will not perhaps admit that there are subjects which thrive best where they are under influence of shade as well as sunshine. Nevertheless, it is true that our north borders—although on them we cannot expect to gather the earliest blossoms—retain for the longest period, during the heat of summer, flowers in a much fresher condition than in almost any other part of the garden, and, this being so, it is worth while considering what plants are better suited for the coolest position. I have observed in gardens where hardy plants are grown that subjects which would be best served by the coolness to be found on a north border are often planted on the south side of the garden, where in the sun nearly the whole of the day their blooming period is but a short one, and they may be seen in a dry summer flagging day after day, having the appearance of being worn out before the season has half gone. Anyone who has had to do with exhibiting flowers knows very well that to ent a certain number of blossoms it is desirable to have a good number to select from, and whilst it is necessary to have blooms well advanced, it is also quite as essential that they should be well developed, cut fresh, and stand removing without dropping to pieces. It is here, then, also where the advantage of a north border is seen. But those who do not grow for show like to have flowers in bloom as long as possible in their gardens, but how often do we hear the remark, when planting something new, "I have put it here, where it can get the most sun" as if that were the one essential to success, little thinking that shade as well as sunshine is beneficial to some subjects. I have seen Peonies, Delphiniums, Phloxes, Pyrethrums, Spiraeas, and other similar plants that like a fair amount of moisture, planted on borders that have been dried up by noon, in consequence of the little depth of soil and a too sunny position, that ought to have been on the north border, where the partial coolness aids in the better development of the flowers. Very many of our hardy plants would grow there—Lupins, Delphiniums, Montbretias, Campanulas in variety, Kniphofias, Lilioms, like tigrinum, candidum, speciosum, Lathyrus latifolius albus, Erigerons, the Day Lily (*Hemerocallis flava*), *Dicentras*, *Polemonium coeruleum* (Jacob's Ladder), Foxgloves, *Spiraea arifolia*, *S. Aruncus*, *Nicotianas*, and *Heleniums*. All these are suitable, and should be given a trial by those who are at a loss to know what to plant. I do not exclude annuals, for I know that if Stocks, Asters, Zinnias, Pansies, and all the summer bedders, are a little late with their blossoms, they invariably are finer, because of that slow development. In making a rockery, I would also choose a north for preference to a south aspect, for there Ferns, Mosses, and alpine plants that delight in moisture are likely to do better. Ferns especially are best served, and those prettily-marked leaved herbaceous subjects—which ought to be on all rockeries—the Funkias. *Anemone japonica alba* blooms remarkably well with me on a north border, as do clumps of Flag Irises. When in the springtime plants are a little longer in revealing themselves where thus grown, it is as well we should think what effect north borders have on flowering plants in August, when so much watering has to be done in other parts of the garden. It is on this side, too, where one can place a cold-frame from June to September, in which winter-flowering plants, like Primulas, Cinerarias, and Cyclamens, etc., are brought on, with the satisfaction of knowing that they will not be unduly hurried nor suffer from overpowering sun.

LEATRIST.

NOTES AND REPLIES.

Aster Townshendi and A. hispidus.

—In Vol. XVII. of *The Garden*, for 1890 (p. 346) is a coloured plate of two beautiful Asters, one violet and the other rose colour, named respectively Aster Townshendi and A. hispidus, and the latter is stated to be synonymous with *Diplopappus asper* (Lessing). I have searched numerous catalogues, but

cannot find these Asters named in any of them. Can any of your readers kindly inform me where they can be procured, and whether they are hardy?—N. B.

[A synonym of Aster Townshendi is A. Bigelowii (Gray), seed of which you can obtain from Messrs. Thompson and Morgan, Ipswich, who might also be able to get you the other plant you inquire about.—Ed.]

Lilium candidum.—The accompanying photograph shows that lifting and replanting do no harm to the bulbs of *Lilium candidum*. In the summer of 1900 there were in my garden two or three clumps of this Lily, and but one solitary flower. On investigation it proved that overcrowding was the trouble, as there were from forty to sixty bulbs in a space about 2½ feet across. These were lifted early in August, dusted with sulphur, and replanted almost at once. The result certainly justified the experiment.—MRS. T. H. BARNARD, Bedford.

[The photograph showed a fine group of healthy, well-flowered spikes, on one of which we counted fifteen open flowers and buds, several of the others being quite as good.—Ed.]

The Night-scented Stock.—I have little doubt but that the plant about which your correspondent "Salf" enquires is *Mathiola tristis*, which may be distinguished from *Mathiola odoratissima* by its linear downy leaves, and from *Hesperis tristis* by its sessile flowers. A peculiarity of the plant, according to my experience, is that it never produces seed. I have had it in cultivation for over twenty years, but although I have time after time pollinated the flowers, and have grown it in the open where insects could have free access to it, I have never seen a seed produced. It is, to my thinking, one of the most deliciously scented of flowers, and the ordinary *M. bicornis* bears no comparison with it in this respect.—J. ROSE, *Randwick-road, Oxford.*

—With regard to the Night-scented Stock, alluded to by your correspondent "Salf" in your April 12th issue, I thank Messrs. Thompson and Morgan are quite right in identifying it with the old-fashioned plant *Mathiola odoratissima* (syn. *M. tristis*). This is a greenhouse perennial much grown in former years, but now almost driven out of cultivation by the annual variety *bicornis*. They are both very sweetly scented at night, but the perfume of *odoratissima* is far superior, one small spray filling a whole room with fragrance. I have cultivated it for nearly fifty years, and if your correspondent "Salf" will send me a directed and stamped label I will forward him a cutting of the plant by post. It is a constant bloomer, and I enclose a spray for your inspection.—THEODORE H. MARSH, *Gawston Rectory, Norwich, April 16, 1902.*

Mesembryanthemum roseum.—I enclose pot of creeper, and shall be much obliged if you will give me the name and any hints on cultivation! I have a large plant, but it has never bloomed. I believe I ought to have a pink flower.—T. K.

[The enclosed specimen is that of a *Mesembryanthemum* (probably *M. roseum*), but as there are over 300 species it is quite impossible to state which of them it is without blossoms. Nearly all the *Mesembryanthemums* are natives of South Africa, and need a soil composed principally of loam, lightened by an admixture of about one-third leaf-mould, and a liberal sprinkling of sand in order to keep it open. The pots must be effectually drained with broken crocks, and the plants given all the sunshine possible. During the summer they may be placed out-of-doors (always in full sun), and in winter stood on a light shelf in the greenhouse, or, failing that, a sunny window where they are safe from frost. From their succulent nature they are in a native state enabled to resist long periods of drought, and under cultivation they need throughout the winter months very little water. If you treat your plant as above, it is very probable that you will be rewarded by a crop of blossoms.]

Hybrid Columbine.—I was recently somewhat surprised to read that the hybrids of *Aquilegia cœrulea*, *chrysantha*, *Skianerct*, and others, were less robust than were the original species. That assertion is entirely contrary to my experience; indeed, that is, to the effect that one result of the inter-crossing, apart

from the remarkable variety of colours and beauty seen in the flowers, is to create a strain of even more robust plants than are the original parents. I have had them growing in diverse positions, and especially in exposed ones, and have found the plants not only to winter well, but each year, up to about the fourth, to become stronger. If then they decline in robustness, it is not due to lack of constitution, but rather to poorness of soil, as the plants are somewhat gross feeders, and need ample manuring. But, seeing they seed so freely, and it is thus possible to save every year some from the very best, a strain can in that way be rapidly improved, and some seed should be sown each year. Last summer I sowed seed in a very open position at the end of August. Now I have myriads of plants to dilble out.—A. D.

Fragrance in the garden.—A word before the spring sowings of annuals are completed may remind someone of the beautiful sniffs obtained from a scented garden, perhaps a little suburban patch, with Honeysuckle clambering over the railings, or Mignonette in little tufts, or, maybe, a hel or row of Night-

grows 3 feet to 4 feet high, and is well worth the slight attention its superb qualities merit. Mignonette emits a sweet perfume at all times, but stronger in the early morning. It does not transplant easily, so should be sown on rich, friable soil and thinned to 12 inches apart: sowings may safely begin by the middle of April. No artificial manures should be given to Mignonette at any time. After the later sowings flower, plants of the earliest sown may be cut back beyond their flower stems, when they will break freely and produce quantities of bloom throughout autumn. Sweet Peas are beautifully coloured, deliciously fragrant, and supply cut flowers in greater quantity than any annual I know. H. H. Grasson, *Ballygunnartin, Belfast*.

Gold-laced Polyanthuses.—It is interesting to learn that there is growing up a demand for these pretty Gold-laced or edged Polyanthuses. Two or three years since, even of a fine strain, seed could not be sold. Now seed is badly wanted. Unfortunately, there are few good strains in the country, and beyond the old named varieties, such as are still grown

thrum or a tiny cluster of pollen anthers. Round the cup must be a clear circle of pure yellow, and next that, with well-defined edge, a ground or margin of either black or red. This, again, must be clearly edged with a narrow margin of yellow of the same hue as the centre, and the edges must in every case cut clean through to the centre ring as well as through each petal. Each flower should have five petals.—A. D.

THE NEW ZEALAND FLAX IN DEVON.

The illustration shows the New Zealand Flax (*Phormium tenax*) growing in the grounds of Parracombe Rectory, Devonshire, at an altitude of about 800 feet above the sea level. The plant has weathered very severe frosts during its existence in its present position, where I planted it about ten years ago, but owing to its exposed situation it has to be protected during the winter months. It is of great thickness through the centre, and many of its long and graceful leaves are from 10 feet to 12 feet in length. It has not yet flowered, and is the admiration of all who have seen it. Being, I believe, the only one of its kind in the neighbourhood. Being a regular subscriber to your valuable paper, and seeing a short article on the New Zealand Flax in your issue of February 15th, I thought this might be of interest to your readers.

JOHN GAMON.

The Chimney Cam-

panula (*Campanula pyramidalis*) is a perennial, but far better results are to be had if treated as a biennial, sowing seed every spring. Sown now in pots of sandy, moist soil, and barely covering the seed, germination will soon take place if given glass accommodation and shaded from the sun. Prick off into pans or boxes of similar soil when fit, and care for until re-established, when stand out-of-doors. Transfer into 4-inch or 5-inch pots before the roots get matted together, as the foliage of all Campanulas is very brittle and soon gets broken. Repot into 8-inch and 9-inch pots when ready, using mostly loam, with a little decomposed manure, a little soot, and enough coarse sand to keep the whole porous. When the pots get full of roots, a little weak manure-water weekly will keep the foliage of good colour. Protect under cold-frames

during the winter, with the pots plunged in

ashes and the lights drawn back by day when fine. The plants will make a grand show during July and early August the following summer. Some gardeners plant them out and place bark in pots towards November; but the plants do not lift very well, and the roots of this variety are so quickly broken that it must give them a great check and be detrimental to their flowering. The plants are hardy, and will make a decent show in the herbaceous border; but to see them at their best, glass accommodation must be given them, as the rain and winds so soon spoil their beauty when in the open. The plants should not be placed under glass until the flowers begin to expand. Blue and white are the only two colours we have at present.—J. M. B.

Dwarf Nasturtiums.—There used to be a pretty variety of the compactum type of *Nasturtium* called *compactum roseum* that was very free, and bloomed for a long season. It was a sport or break from the scarlet *compactum*. I do not know whether good stocks of these *compactum* forms still exist. They were plentiful some twelve to fifteen years ago.

The New Zealand Flax (*Phormium tenax*) in a Devonshire garden. From a photograph sent by Mr. J. Gamon, The Rectory, Parracombe.

scented Stock (*Maltholia bicornis*), or dwarf edgings of Virginian Stock, with its pale rose, lilac, and white flowers; or a Rose-tree covered with flowers trained to the wall. Speaking of Rose perfume makes one wonder why our raisers of Roses pay so little attention to the fragrance of new kinds. Those of us who have lived long enough may remember the country cottage wreathed in the white blossoms of Alma, pink flowers of Gallica Bellard, or the sweetest of the good old Roses of long ago, Gallica Damascena, or Gallica phoenicea, the former blush, the latter crimson, and overflowing with sweet perfume. The Sweet-scented Tobacco (*Nicotiana affinis*) is a noble plant and richly scented, especially in the evening, when its pretty flowers unfold the white petals which close up during the day. Those who are from home all day should grow this plant. It is a half-hardy annual, so should not be sown outdoors before the middle of May. Gardeners sow it in boxes during March and protect it with glass; thus they get large plants to put into their beds in the first week of June. Lower grown, *Nicotiana* like *glauca* and *glauca* in

in Lancashire and other northern counties, there are very few of these named varieties about, hence there is but a poor stock to furnish seed. Common strains of Gold-laced Polyanthuses are often the merest of rubbish—useless for exhibition, and as garden flowers a long way inferior to the good showy border Polyanthuses. Just a few of the named varieties, though seldom seen in proper condition, may be as a rule found at the customary exhibition of the National Auricula Society, held in London at the end of April, but they are seen in much better form at the midland and northern shows. If it were possible to get a seed strain that would furnish flowers of fair show quality it would be a great gain, as old named varieties that have to be propagated by division are difficult to keep, especially in the south. Gold-laced Polyanthuses have both black and red grounds, but reds are very scarce. The flowers or pips should be of moderate size, rounded and flattish. They should be carried on stout main-stems, and form a small but neat compact truss. To meet a judge's requirements each flower must have a purple centre filled with what is called a

These differ materially from the well-known Tom Thumb type, which includes Ruby King, King Theodore, and several others. These come very freely from seed, but their flowering period is rather brief, because foliage so soon dominates and hides the bloom. The compact forms, on the other hand, if the soil be fairly firm and not rich, will spread about, the leafage lying near the ground and flowers breaking up profusely for a long season. Whilst well set and isolated forms come true from seed, any variety can be propagated most readily by means of cuttings inserted in pots early in September and kept in a greenhouse all the winter.—A. D.

ROOM AND WINDOW.

DORONICUM PLANTAGINEUM HARPUR-CREWE.

THIS is the best of a handsome family of hardy spring-flowering plants. There are several fine *Doronicums* in gardens, but there are more

Flowers of *Doronicum plantagineum* Harpur-Crewe in a vase.

names than distinct varieties, which leads to some confusion. It is important to know and grow the best of them. The varieties found in gardens can mostly be referred to two species—namely, *D. pardalianches*, which is distinguished by its rounded woolly leaves and tall flower-stems, 3 feet to 4 feet in height, and *D. plantagineum*, with larger flowers on shorter stems and more ovate leaves, resembling those of the Plantain. The variety named Harpur-Crewe originated in the garden of the gentleman whose name it bears, and its great merit is that of continuous blooming. From early spring to late autumn it will maintain an abundant succession of its fine flowers if rightly treated. In common with all the *Doronicums*, it is easily increased by division, which should take place frequently at different times, so as to secure strong batches of young plants succeeding each other in flowering. Besides the brilliant effect it gives in beds and borders, mention must be made of its merits as a cut-flower, for which it is useful and lasting. Those who have reserve gardens to supply flowers for the house will find this plant of great service.

CHRYSANTHEMUMS.

TWELVE BORDER SORTS FOR PRESENT PLANTING.

(REFER TO "R. S.")

Your inquiry for a dozen early-flowering *Chrysanthemums* suitable for a town garden, and for present planting, we are pleased to respond to, as we know the value of these plants in the dull months of the year. We have included a few of the better Pompons. Do not plant them too close together. None of the sorts mentioned in the following list can be regarded as of weakly and sickly growth. Plant firmly, and when the soil is moderately dry. Secure plants of the following varieties, which any of the leading growers should be able to supply you with at a low figure:—

JAPANESE.

MADAME CASIMIR PERIER.—This is one of the earliest of the border Japanese kinds, the plants producing freely blooms of rather large size. The colour may be described as white,

variety blossoms from early August until the end of October.

MARKET WHITE.—A chaste white sort, of which there are too few among the early-flowering Japanese *Chrysanthemums*. This variety is included in this brief list because the plant is of a capital bushy and sturdy habit of growth, and is also a free-flowering kind. For cutting it has an especial value. Height about 2½ feet. In flower during October.

DE LA GRILLE.—It is a matter for regret that this plant is so little known, although it has now been in commerce for some years. Apricot-tinted bronze, is a good description of its colour. The habit is bushy, and fairly compact, and it is free-flowering. Height about 2½ feet. In flower during October.

NOTAIRE GROZ.—This is taller than the others already mentioned, and is therefore well suited for a position at the back of a border, or any equally important situation. Some describe its habit as "struggling," but this can hardly be considered accurate. It is free-growing as well as free-flowering. The plant will need the support of a stout stake, to which the growth should be lightly looped. Height about 4 feet. Colour silvery-pink. An October sort.

HARVEST HOME.—This is useful for its colour, which is a shade of bright crimson, tipped golden-yellow, and with a golden reverse. It is not so free-flowering as we would desire, nor is its habit of the best, yet for September and October blossoming it is highly prized. Height about 3 feet.

POMPONS.

MRS. CULLINGFORD.—One of the best and largest of the Pompons. It is a free-flowering variety, developing a wonderful crop of blossoms, and covering a period from early September till October is well advanced. In the open the colour is creamy-white, while under glass it is of the purest white. Height about 2½ feet.

ALICE BUTCHER.—This is a reddish-orange sport from a variety named Lyon. It is very free-flowering, and unless partially disbudded, the weight of the blossoms causes the growth to overhang, so that the plant is not seen to advantage. Height about 2½ feet. In flower from the latter half of September till the severe frosts ensue.

MR. SELBY.—A pretty little kind, which all interested in these plants should grow. Its height does not exceed 18 inches, and the flowers are freely produced. The habit is bushy and compact, and the growth vigorous for so charming a representative. Colour, peach-pink. Period of flowering late August, September, and early October.

MRS. E. STACEY.—This is a pleasing deep apricot sport from the last-named variety, and, except for its colour, identical with the parent plant. We saw this in superb form last season, and are somewhat surprised its high quality has not been recognised before.

E. G.

FERNS.

* * HARDY FERNS AND THEIR CULTURE.

ALL my life I have loved Ferns. To seek after them in their own homes, by hill and dale, and in lovely shady woods in England, Ireland, and Scotland has been a pleasure to me, and when at last I found the much coveted variety, it was carried home to be carefully planted with many old favourites. Many of our native Ferns will flourish in shade, others like a little sunshine. I will begin by naming a few of the *Polystichums* as they are most of them easy of culture. Many are tall, handsome plants. Amongst our native species, *Polystichum aculeatum* var. *lobatum* is perhaps one of the finest when really well grown. *P. angulare*, *P. aculeatum*, *P. a. acutum* dissectum (this last having wonderful spores on the underside of the fronds), *Wollastoni*, *Kitsoni*, etc., all are fine kinds. They grow readily in a compost of leaf-mould and rough sand. *Polystichum Lonchitis* (Holly Fern), is not so easily suited with a home. It requires peat, as well as the compost mentioned, and some bits of limestone. Should it not flourish in one part of the rockery it is wiser to move it. It does not love shade. The *Lastreas* are very beautiful, the Evergreen *L. dilatata*

freely suffused, and tinted pink. Height from 2½ feet to 3 feet. Period of flowering, September.

MADAME MARIE MASSE.—The habit of this is branching, and it is one of the most profuse blossoming sorts we have. The colour is a shade of bright lilac-rose. Height from 2½ feet to 3 feet. In flower from late August till October is well advanced.

IVY STARK.—An English-raised seedling, possessing an ideal habit of growth. The form and colour of the flowers remind one of *Sourcil d'Or*, so largely grown for market in late October and November. The colour is generally described as orange-yellow. The plant is free-flowering, and comes into bloom in the latter part of September, continuing to bloom all through October. Height about 2½ feet.

CRIMSON MARIE MASSE.—This is a chestnut-crimson sport from *Madame Marie Masse*, the characteristics and beauty of which plant are fully described above. When the flowers first open their colour is very fine, but with age they pale until at last the shade of colour represented may be considered a good bronze. The

and the crinkled-leaved *L. recurva*, or *Foenici* (Hay-scented), as called by some. It makes a very pretty object at the back of the fernery, planted on a bank about 3 feet high, built of stones and peat, the stones just enough to prevent the peat giving way, the Ferns inserted here and there. At the foot of the bank, which is about 6 feet long, I have colonies of *Polypodium Dryopteris* (Oak Fern), and *Polypodium Phlegopteris* (Beech Fern). They are easily grown in a mixture of leaf-mould, peat, and coarse sand, but do not like sunshine. The Beech Fern is rather capricious, but it is well worth taking trouble to make it flourish. Among *Lastreas*, *L. spinulosa* and *L. cristata* are both desirable. I have never found either of them growing wild but purchased them for my fernery, and they are doing well. *Lastrea nelypteris* and *L. montana* prefer the dampest spots available. The former is a charming Fern, and lovely when seen in masses in its wild habitat. It increases rapidly, pushing its creeping caudex along the ground, and loving sand and peat. *Lastrea rigida* prefers a little rough limestone with the other ingredients before mentioned.

The *Aspleniums* are charming. *A. Adiantum-nigrum* seems at its best in a hedge, wall, or bank, as also *A. Trichomanes*. *A. viride* is an addition to any Fernery, but a rather trouble-

successfully *Asplenium lanceolatum*, although sent to me direct from its native Cornwall. Parsley Fern (*Allosorus crispus*) has also disappointed me. It requires slaty shale, and that I could not give it. There are also a few very pretty hardy foreign Ferns that are a great adornment to the fernery—as *Polystichum munitum*, rather like Holly Fern. *Adiantum pedatum* (the Canadian Maidenhair) is lovely—it requires a little protection, such as Cocoa-nut-fibre or peat-mould in winter. *Onoclea sensibilis* is very ornamental and a Fern that increases rapidly. It is rather like a Polypody. I had almost forgotten to mention *Osmunda regalis* (the Royal Fern). I grow it just outside my fernery in beds containing each about twenty-five plants. It loves peat and a moist situation, and grows from 4 feet to 5 feet high. The foreign varieties, *Osmunda gracilis* and *O. cinnamomea*, are much smaller and pretty. My fernery is diversified by raised mounds, and here and there a medium-sized rock to give variety and form miniature hills and valleys. One other foreign Fern I should like to mention—*Struthiopteris germanica*. It grows freely in loam, peat, and sand, forming large circular crowns of long green fronds, and sending up long stems from the centre with the spores.

I have often heard that it is not well to have other plants grown in your fernery, but I have

FRUIT.

UNHEALTHY PEACH-TREES.

(REPLY TO "SWISS SUBSCRIBER.")

You will find much useful cultural information in the perusal of the note to which you refer, though the complaint in that instance is not the same as that which affects your trees. From the description of your soil and roots there are certainly not the conditions present for successful Peach growth, and we strongly advise you in the coming autumn to procure fresh soil of a lighter nature, preferably turfy loam from a Grass-field, dug up in turves from 2 inches to 3 inches thick. Mix with this some lime-ribble and burnt refuse, but no manure of any sort, and provide also some drainage, coarse stones or broken bricks about 3 inches in depth, before putting in the soil. This should be chopped up roughly, and the lime-grit mixed with it, making sure that it is trod firmly together. We are not sure whether it would not be more economical to purchase new trees than to attempt to restore such unhealthy ones to a useful state. This, however, is a matter best decided by yourself. Certainly mulch the trees in May with spent manure, and let it remain on all summer, and in dry weather water freely. Probably some lime is needed in your soil, and, in any case, it would do good. Procure fresh air-slaked lime, spread on the surface not more than a 1-inch deep, extending to a radius of 3 feet or 4 feet, and if there is no rain, water in with clear water. On very hot walls Peaches must be regularly syringed in the evenings of hot summer days. A garden-engine is the best for this, unless, of course, a hose and a plentiful water supply are at hand. From this or a garden-engine there is a continuous delivery, which is much more effective in dealing with insect-infested leaves. There is every indication of your trees suffering from red-spider— one of the smallest, yet most destructive of garden enemies. If you have not given your trees this attention, you may satisfy yourself that this is one direct cause of the premature falling of the leaves. This trouble comes even in British gardens where the sun is less powerful than in Switzerland. A good drenching with water on hot summer evenings not only disposes of red-spider, but stimulates the trees. Without leaves it cannot be expected that fruit can become full grown and properly ripened, and nothing so quickly causes defoliation as drought and red-spider. With healthy trees and new soil not much feeding is necessary in Peach growing, but when well established and in full bearing an annual dressing of some artificial manure does much towards maintaining the tree and crop. It is best put on in spring, if artificial watering cannot be resorted to, for these artificial manures are not of much value without moisture. A dressing of either of these dry manures should be followed by an immediate mulching of spent stable-manure, but first point up the surface, say an inch deep, with a digging fork, so that it is well incorporated, and not so easily washed away when watering is done. On such heavy land planting must be carefully done, few trees succeeding when their roots burrow deeply into clay. Every encouragement should be given to keep the roots near the surface, which is best done by mulching to shut out fierce sun and drying winds, and an occasional watering in dry periods. Washing of the leaves, as before noted, is an important item for summer evenings, neglect of which is sure to be a cause of red-spider, and if this goes unchecked premature falling of the leaves is inevitable.

Plum-trees weak.—In January last I planted a couple of standard Victoria Plum-trees, which look to me somewhat weak and struggling in growth. The branches are about as thick as a well-grown Raspberry-cane (say half an inch or less), about 4 feet long, and tapering to a point. Buds are beginning to break on them. Ought the branches to be cut back, and if so, to within what distance of the stem? Is it now too late to cut them back? I do not want, of course, to run the risk of damaging the trees.—LISTER GIBBS.

[It is unfortunate that a few weeks after you planted the shoots on them had not been shortened back to fully one-third their length. Had this been done, the dormant buds on part of the cut shoots would have broken and

A group of the Royal and Male Ferns in an Irish garden.

some one, as it requires moisture with good drainage. *Ceterach officinarum* is curious from the dense fructification at the back of the fronds. It is easily grown, doing best between stones at the edge of the fernery. A good companion for it is *Cystopteris fragilis*, so pretty and delicate-looking. *Cystopteris Dickiana* is a good variety. After many trials I have at last succeeded in establishing *Cystopteris montana*, being kindly sheltered by a large plant of *Athyrium Filix-femina* (Lady Fern). *C. montana* has been found near Ben Lomond a few years since. The Lady Ferns in my fernery are a great feature, as I have many very nice varieties, from the tall crested and tasselled var. to the curious Victoria, in which the segments of the fronds seem to cross each other. The stately Male Fern (*Filix-mas*) ought not to be forgotten. It is represented by the common one, and also many cultivated vars., such as *cristata*, *polystichum*, etc. The fine green sword-shaped fronds of *Scelopendrium vulgare* are quite a novelty to any fernery. Very easily-grown and many pretty and quaint varieties can be purchased at a small price. Late in the autumn when the Lady Ferns are losing their first freshness, we are cheered by the bright green of the Polypodiums. Good vars. are *P. cambricum*, *P. semilacorum*, *P. omnilacorum*, etc. *Blechnum Spicant* (Hard Fern) makes a nice change, and a pretty plant when it grows well, but it requires a good deal of peat. I have never been able to grow

allowed two or three charming guests to take up their abode here. Patches of Snowflakes, *Leucunum vernum*, not the taller *astivum*, a few double white and double lined Primroses, and my great favourites—the pink and white autumn-flowering *Cyclamen neapolitanum*. They are very attractive just when some of the earlier Ferns are turning yellow.

M. S. KNOX-GOUR.

Belleek Manor.

Wall for hardy Ferns. I was much interested in the article on page 105 about a Fern-clad wall in a conservatory. I want to try it in the open, on a wall facing east, and sheltered by trees from morning sun. Kindly tell me which hardy kinds would do, if properly watered? The whole house and garden are in a very sheltered dell, away from biting winds.—BELGIAN READER.

[The following Ferns would succeed under the conditions named by you—that is, if carefully planted and watered when necessary: *Asplenium Adiantum-nigrum*, *Asplenium Trichomanes*, both evergreen; *Athyrium Filix-femina* and its numerous beautiful and dissimilar varieties; they are, however, all deciduous. *Blechnum Spicant* and its forms are evergreen. *Lastrea Filix-mas* (Male Fern) is partially deciduous; there are several varieties of this. *Polypodium vulgare*, some of the forms of which are very beautiful, is evergreen. *Polystichum angulare* is nearly evergreen, and many varieties. *Scelopendrium vulgare* (Hart's-tongue Fern) is evergreen, and numerous beautiful forms of this are in cultivation.]

carried three or four new shoots from each, and thus have formed on each tree a sturdy head, fairly close home. During the autumn, if these shoots seemed to be too dense, a few could have been cut out. Those shoots left would have needed shortening back just a little in the succeeding winter, and afterwards the heads would simply need thinning only. Now, with the long shoots you have on your trees, many of the buds will not break, but will, no doubt, form fruit-buds, so that probably next year these branches may be thickly hung with fruit. That is a source of danger always to Victoria Plum-trees, as because the fruit becomes so heavy and the wood is so brittle branches break off freely, and the trees are thus greatly damaged. Where such heavily-fruited long branches exist, each one should be supported by a tall stake, to which it should be tied. It is not even now too late to prune these long branches, but if you resolve to shorten them let it be to one-half their length now, as in that case the summer shoots will be less gross, and may be more easily ripened. These may be pinched at the joints at the end of August, and that will induce them to harden or mature earlier. Whichever course you may take with the trees, see that each one has the support of a stout stake, and also that a mulch of long manure is placed about over the roots to check loss of moisture. If your soil seems dry, give the roots an occasional good watering, unless heavy rains come.]

GARDEN WORK.

Conservatory.—Sow Chinese Primulas for early blooming in heat, as in a low temperature the seeds are a long time germinating. Cover the pans or pots with glass, and keep in a shady part of the house till the seeds germinate; afterwards place in a light, cool place. Double Primulas which have done flowering may be mossed round at the base to encourage roots to form there in preparation for cutting up later on. A few of the plants in 48's may be shifted into 6-inch pots to make large plants; but the flowers on young plants are the finest. Double Primulas must not be overwatered at any time, and from May onwards we keep our plants in a cold-frame lightly shaded, watering carefully only when really required. Celosias, both the plumose section and the old-fashioned Cockscorn, when well grown are useful plants. The seeds should be sown now in heat. They do famously at the start in a hot-bed like the early Cucumber-frame, and kept close for a time. Balsams should have similar treatment for a time at the beginning, and when fairly started air must be given freely. There is great virtue in the hot-bed for improving little plants at the start, but they must not be kept in the bed too long. At this season young stuff must be kept continually on the move. Young Tree-Carnations should now be placed in single pots, and the best place is a cold-frame, well ventilated. Later they may be placed on a coal-ash-bed outside. Any plants should be stopped to induce several shoots to start. When the present pots are filled with roots, shift into 5-inch pots and put a stake to each plant. In the 5-inch pots the plants will flower. In the second year they may be shifted into 6-inch or in some cases 7-inch pots, and after flowering the second year throw them out. Thus, when the flowering season arrives, there will be yearlings flowering in 5-inch pots and older plants in larger pots. The latter will, of course, produce many flowers. Strong plants of *Campanula isophylla* alba, C. i. Mayi, C. Balchiniana, and C. garganica are all useful conservatory plants for baskets.

Stove.—The plants grouped as "Bromeliads" seem to have gone out of favour; nevertheless, there are several things among the *Bilbergias*, *Echmeas*, and *Tillandsias* that would be appreciated by those who are looking for more variety. *Echmea fulgens* is a quaint, interesting plant; *Bilbergia Leopoldi* and *B. Sanderiana* are striking things; and the same may be said of others of the same group which have disappeared from many collections. None of these are difficult to cultivate, and they will do in an ordinary stove temperature. This

the best time to fill baskets with Ferns and other suitable plants. Growth now is vigorous and rapid and things soon get established. These may be suspended under Vines if there is no room in the stove. Years ago we used to grow a lot of things in baskets in this way that were afterwards, when well established, taken to the conservatory. *Achimenes* do well in the shade of Vines when making growth. There is a large Grape grower in Norfolk who grows *Dendrobium nobile* in baskets under the Vines: the plants are of large size and produce thousands of flowers, which help to compensate for the falling price of Grapes during the last few years. There should be plenty of cuttings of *Poinsettias* now; soft young shoots 3 inches long will soon strike if kept close in a brisk bottom-heat. Look out for thrips on *Croton* and other smooth-leaved plants. It is a singular thing these troublesome little insects never attack hairy-leaved plants. They require a clear field for their work. Nicotine in vaporisers is the best remedy for insects; it is more penetrating than smoke from Tobacco.

Orchard-house.—If there are Grapes in the orchard-house, the canes should be trained thinly so as not to unduly shade the trees beneath. Peaches want plenty of sunshine, and the fewer Grape-Vines trained on the roof the better. But if a few Grapes are wanted, the Vines may be grown in pots or tubs, or be planted in the border and trained perpendicularly. I was in an orchard-house last summer where a series of arches were formed over the central path of a rather lofty span-roofed house, and over these Black Hamburg and Foster's Seedling Vines were trained alternately, and appeared to be doing well. In this case the path only was shaded, and the house being roomy, the Grapes were a decided improvement in every way. Every item of the usual routine work is important now, and arrears in this respect cannot be fetched up, or in other words, delay means injury. When the sublaterals on a Grape-Vine are permitted to run out, harm will certainly result. The same thing occurs when the young wood on Peaches remains too long in an over-crowded condition.

Cucumbers.—This is a time for increased attention to stopping, training, top-dressing, and other routine work, which must not be delayed. It is a time, too, of planting hotbeds, and the time is near when Cucumbers may be grown in cool-houses without fire heat, beyond a little, it may be, just to start them on their way. I have had good summer crops of Cucumbers in cool-houses in the following way: A thick layer of warm stable-manure is laid in a ridge along each side of the houses, which are span-roofed. A layer 1 inch thick of soil is placed on the manure to keep down the harmful effects of the ammonia, and as the small hills of soil are placed the Cucumbers are set out. No air is given, but the atmosphere of the house is kept in a constant state of saturation. The growth is very rapid.

Outdoor garden.—Seeds of biennials and perennials may be sown now. Anything choice should be sown in a box or boxes if there are many seeds, as thin sowing is desirable, even when it is possible to prick the little plants out in nursery beds to get strong as soon as they can be handled. The advantage of sowing the choice things in boxes lies in the fact that they can be kept close and moist, and, if necessary, shaded. We prefer to keep the seed-boxes in a cold-frame, though, in some cases, the frame is of a temporary character, and only covered with oiled calico. Of course, common things, such as Wallflowers, Sweet Williams, Canterbury Bells, and robust things generally, may be sown outside. Among the most useful things for cutting are Everlasting Peas, the roots of which may be divided now they are just breaking into growth. The plants do not come true from seeds, though all the forms are useful. Two years ago we saved seeds from a very fine white-flowered form and raised quite a number of plants. Most of them flowered last season, and there were several among them with coloured flowers. Iceland Poppies are charming in a mass, and a good way of getting up a stock of plants is to let them sow themselves, and then transplant. The seeds are very fine, and soon lose their vitality. New seeds are best. Bedding plants of all kinds should be hardened in cold-frames.

Fruit garden.—Cracks, if any, must be stopped in the clay where grafting has been done, and as soon as the grafts are growing freely short stakes must be attached to the trees to support the young shoots and prevent injury from winds. Apples on the Paradise and Pears on the Quince should be mulched with good manure, but do not pile it up round the main stems. The Cape Gooseberry (*Physalis edulis*) will grow very well against a warm fence or wall. I once had a small span-roofed house planted with it along the side and trained up like Tomatoes. Recently-planted Raspberries must be cut down nearly to the ground. Let them have one season to make strong canes, and then for some years, six or seven at any rate, we are sure of a crop. A mulch of manure will be useful in keeping the roots moist. Strawberries in pots must never be permitted to get dust-dry or the fruit may be hard and flavourless. Dishful Figs under glass. Stop newly-planted Melons in frames, so as to get at least four breaks to be trained towards the corners of the frame. When top-dressing is required use good heavy loam and make firm. The blossoms on fruit-trees are most abundant. If a good setting time comes a good crop is assured. See that the roots of trees against warm south walls are sufficiently moist. Up to the present the rainfall in some districts is below the average. Spring-planted Strawberries should be watered till established.

Vegetable garden.—Stirring the soil among young crops just up is most important work, and should not be delayed a single day when the weather is suitable. There is a double advantage in this—it kills the weeds when small and encourages the growth of the plants. Make new plantations of Globe Artichokes and mulch heavily with manure. This is a crop which requires high feeding to do its best. Use a proper knife in cutting Asparagus and do it carefully. Use the hoe freely among young plants just up. Asparagus-beds usually are weedy places, but a good dressing of salt at the proper season will do much to keep down weeds. Salt may be used freely on porous land as a check against drought. Half-a-pound per square yard will do no harm to anything at any season. We have used it at this rate among growing crops. It must be scattered evenly. Soot will be useful sown thinly over young Onions, and nitrate of soda will rush the crop past the attacking time of the Onion-fly. Sow French Beans and Scarlet and other Runner Beans to meet all demands likely to arise. Prick out Winter Greens if crowded in the seed-beds. Cardoons may be sown now in the trenches, 15 inches apart. Prick out Celery and sow a few seeds in cold-frame for late use. Plants from this late sowing will not bolt so soon.

E. HUBBY.

THE COMING WEEKS WORK.

Extracts from a Garden Diary.

May 5th.—Potted off cuttings of several kinds of *Campanulas* with drooping habit, and which are so useful for basket work. If we want to make a specimen speedily, three plants are placed in a 5-inch pot, which is afterwards shifted into a pot a size larger. All early-struck *Chrysanthemums* are being shifted into 6-inch pots. Certain kinds have been stopped previous to repotting. Tuberous *Begonias* intended for conservatory are now in the flowering pots on stages near the glass.

May 6th.—Planted more seeds of Vegetable Marrows and ridge Cucumbers. Sowed more Marrow Peas. One never has too many good Peas in July and August, and several sowings will be made during this and next month. Planted more French Beans and Scarlet Runners. Canadian Wonder is a reliable kind of the former, and, for home use, a good type of the old Scarlet Runner is quite as useful as the very large podded kinds. We are growing Veitch's Climbing French Bean, and shall sow the white seeds later.

May 7th.—There is likely to be a large demand for bedding plants, especially those with red, white, and blue flowers, this season, and we have made provision for having masses of those three colours with hardy plants, such as *Dolichiums*, *Chrysanthemum maximum*, and red *Epilobium* groups of *Clematis Jackmani*

LAW AND CUSTOM.

Trespassing poultry.—My neighbour's meadow adjoins my garden, and his fowls enter my garden and damage my crops, etc. I have complained to him in writing, but he contends that I must so fence my garden as to keep his fowls out of it. What is my position?—W. H. M.

[The tenant or occupier of a garden adjoining a Grass field may be under an obligation to fence against ordinary stock running on the Grass, but no such obligation extends to poultry. Unless your neighbour can prove an express obligation on your part to fence out his poultry, he must keep them out himself or be liable in damages. Your remedy is by action in the county court. But if you had covenanted to build a brick or stone wall between the garden and the meadow, and you neglected to fulfil the covenant, your neighbour would not then be obliged to keep his poultry at home, as their trespass would be due to your own breach of covenant. It is only under such circumstances that you are required to fence the poultry out.—K. C. T.]

Quitting market garden.—In 1894 I took 4 acres of land for market gardening, and in September last I received a year's notice to quit. I sell all my flowers, garden stuff, etc. When I quit can I claim compensation for crops not ready for removal? I have also put up a greenhouse and some buildings. Can I claim compensation for these?—R. T. L.

[Your tenancy commenced before the Market Gardeners' Compensation Act came into force, and so unless you had, previous to January 1st, 1896, and with the knowledge of your landlord, executed some of the improvements mentioned in that Act, it does not apply to your tenancy. If it does apply, you may on quitting claim compensation for the greenhouse and buildings since erected, and for such garden crops as continue productive for two or more years, but you cannot claim under the Act for crops sown or planted during the last year of your tenancy. You may claim under it for fruit-trees and fruit-bushes permanently planted out, but not for flowering plants and shrubs. If you cannot claim under the Act for the greenhouse and buildings, you may put these down and take them away.—K. C. T.]

BIRDS.

Death of Canary (Silver Plated).—This fine bird appears to have died from atrophy, a wasting disease very frequent amongst cage-birds, and unless the treatment of it be undertaken at the very commencement there is very little chance of recovery. It is usually brought about through errors in diet, a prolonged course of unnatural feeding provoking so great changes in the digestive organs that they become incapable of assimilating any kind of food. You fail to furnish any particulars whatever as to diet, general treatment, and so forth. Feeding and indulging birds with sweet, pampering food, and keeping them too warm, or in an impure atmosphere, tend very much to weaken the constitution and bring about this complaint.—S. S. G.

Lovebird plucking out its feathers (Mrs. Sheffield Neave).—The habit of feather-eating when once acquired is very difficult to cure. When a bird is kept in an over-heated temperature a gross condition of the system is often produced, with irritability of the skin, giving rise to this bad habit. Sometimes it arises from the cage being infested with parasites, which at night issue forth and torment the inmate. Maybe your bird plucks out its feathers from want of something else to do, and you might supply it with something on which to exercise its beak, such as a small bundle of twigs or a small piece of soft, non-splintering wood. Smearing the body with vaseline has been found to have a beneficial effect in a case of this kind. Occasionally a bird will leave off feather-eating as suddenly as it began, and after a week or two look as well as ever; but, as a rule, it is just the reverse, and it will keep up the habit until at last it dies from taking cold through its lack of plumage. Supply your bird with abundance of coarse grit sand, having some old powdered mortar mixed with it. The diet, while nourishing, must not be of too stimulating a nature. A little diluted-milk may be given occasionally, but no sweets of any kind.—S. S. G.

CORRESPONDENCE.

Questions.—Queries and answers are inserted in *GARDENING* free of charge if correspondents follow the rules. All communications should be clearly and concisely written on one side of the paper only, and addressed to the Editor of *GARDENING*, 11, Furnival-street, Holborn, London, E.C. Letters on business should be sent to the Publisher. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper, and not more than three queries should be sent at a time. Correspondents should bear in mind that, as *GARDENING* has to be sent to press some time in advance of date, queries cannot always be replied to in the issue immediately following the receipt of their communication. We do not reply to queries by post.

Naming fruit.—Readers who desire our help in naming fruit should bear in mind that several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being nipped and otherwise poor. The difference between varieties of fruit are, in many cases, so trifling that it is necessary that three specimens of each kind should be sent. We can undertake to name only four varieties at a time, and these only when the above directions are observed.

PLANTS AND FLOWERS.

Aconitum (Belgian Reader).—All the Aconites are dangerous from their poisonous roots. They should never be planted where the roots could by any chance be dug up in mistake for edible roots, as they are so deadly. We should certainly not allow them to be grown where children are.

Hyacinths after flowering (C. H. A.).—It is of no use relying on these for flowering in pots the second year. You ought to plant them out in a sunny border. They will then yield you a crop of bloom every year; certainly not so fine as bulbs in pots, but such as will repay your trouble. You will find such flowers very useful for cutting.

Destroying woodlice (Hilda).—We destroy them by cutting Potatoes in halves, scooping out a little from the centre, and laying them down, flat cut side under; the pests crawl under the Potato, they are found there in scores in the morning. Another good plan is to wrap a boiled Potato up in dry hay, put it in a small pot, and lay the pot on its side. This is a favourite haunt for them. They can then easily be destroyed by dropping them into a pan of boiling water.

Renovating a lawn (Pochman).—Your lawn has coarse Grass on it only because it has not proper lawn Grass. You could now roughly rake the bare places, add some sifted soil, then get and sow proper lawn Grass seed. At the same time get sulphate of ammonia very finely crushed, and sprinkle that over the lawn, at the rate of 1½ per rod; or, failing that, some sort of guano. Next autumn get 4 lb. of basic slag per rod to wash in. Ask the seedsman for Grasses suited for a clay soil.

Cyclamens after blooming (Penbrook).—When they have done blooming you should stand in a cold-frame, watering as carefully as if in bloom. Cover if there are any signs of frost, and do not grow in any way. As they show signs of going to rest lessen the water supply until June or July; they will not need much. If you put a little moister after this the young leaves will soon start, when they may be shaken clear of the old soil and repotted in a mixture of loam, leaf-mould, and sand. It is advisable to sow a pinch of seed every year to have young corns coming on to take the place of the old ones.

Pinks from seed (C. H. A.).—If, as we assume, you refer to ordinary garden Pinks, then certainly they can be raised from seed. Still, it depends on the quality of the strain. You can purchase seed of double flowers at from 1s. 6d. to 2s. 6d. per packet, which should give some good double varieties. You can also purchase more cheaply seed of single-flowered garden Pinks, all very beautiful, but not so well liked as are double-flowered ones. If you get seed and will sow it at once, either in shallow pans or boxes, and place in a greenhouse or frame, or outdoors under a handlight, you should soon have plenty of plants.

Cactus Dahlias (Amateur).—Twelve good varieties are Keyne's White, Mrs. J. C. Crewe, lemon yellow, Lady Penzance, white; Major Tuppenny, outer petals orange-carmine, centre yellow; Arachne, petals white, siler crimson; Emperor, rich plum; Mary Service, pinkish heliotrope; Mrs. Carter Page, velvety crimson, lit up with yellow; C. Woodbridge, crimson; Magnificent, buff; Banjil, dark; and Harmony, apricot. Good early-flowering Chrysanthenums are Miss Peckgraves, white; Mrs. Hawkins, Marie Masse, Harvest Home, Roi des Precoques, and Queen of the Earlies. See article in present issue on "Early Chrysanthenums," p. 132.

Growing Coleuses (A. B.).—Coleuses are very tender plants, and can only be kept alive through the winter in a warm greenhouse. During the summer they do well in pots in an ordinary greenhouse frame or window, or even planted outdoors about the second week in June. They grow very fast, and if grown in pots must be given at the first potting 3-inch pots, then as they grow stronger they must be moved into 5-inch ones, and if large plants are wished into 9-inch and 10-inch pots. If you desire to have dwarf, bushy specimens you must pinch occasionally. Coleuses must have a rich, light, loamy soil, to which have been added some well-rotted manure and leaf-mould.

Camellia and Lapageria leaves injured (Constant Reader).—The enclosed leaves look as if they had been growing in a close, warm structure, with little, if any, ventilation, and they are burnt by the sun shining directly on them while moist. Both plants need a free circulation of air for their successful culture. As you give no details of the treatment or conditions under which the plants are growing we can give but little advice in the matter, but may say that no fire heat will now be needed for either the Camellia or Lapageria. Water from a newly painted structure would also injure the leaves. When speaking of the plants give more details, as they are very necessary.

superba and Henry (white) we hope to have in good condition. Phacelia campanularia, blue, Godetia, white, and Scarlet Flax will give us the same colours. In annuals our aim is to have large masses. Cucumbers in bearing are top-dressed frequently. Young plants are always kept in stock.

May 8th.—Most of the bedding plants are hardening in cold-frames; some are under temporary shelter. Calceolarias and Pentstemons will be planted out immediately. Holly-hocks have been mulched with manure, and a good soaking of water has been given. Dahlias are in cold-frames hardening off. We grow chiefly Cactus varieties. Specimen Fuchsias have been pinched for the last time, and the plants are staked securely as pyramids. Younger plants are still in course of training.

May 11th.—Shifted a lot of Tomatoes into such pots to get strong for outside when safe. Early Tomatoes under glass are setting fruit. We are still using a little fuel to hasten the growth of the fruit. The plants have been mulched with Moss-litter-manure to save labour in watering. All side shoots are promptly removed and the main ones secured to stakes as they advance in growth. The ventilation is as perfect as possible. Cold-houses are being planted with Tomatoes. Violets recently planted are watered and the surface of the ground hoed.

May 10th.—Pricked out more Celery outside. The plants are kept thoroughly moist, but no shade is used. The Peach walls are looked over twice a week. We have not removed the coverings, but we are watching the weather with a view to their removal. Work in the vinery and Peach-houses now is incessant, and must not be neglected. This is the time the foundation for a good crop next year is laid. The young fruits are thinned early. We want quality as well as quantity, but the former stands before the latter.

POULTRY.

Red spots in eggs (Fluffy).—You are probably feeding your hens on food of a too stimulating character, for when blood-red spots appear in eggs they show that the ovaries are ruptured, and this is caused in numberless cases through over-feeding. If you can find out which of your hens lay the discoloured eggs, separate them for a time from the others, and feed on very plain food, and that in very limited quantity, with the object of checking egg-production, that they may rest for a while. Feed all your hens more sparingly, and avoid a too liberal supply of Maize. The free use of Maize in the poultry yard is the cause of a greater number of ailments than many people suppose.—S. S. G.

Chickens dying.—My chickens are dying off as they did last year, and I cannot account for it. The eggs, and apparently the healthiest, are first affected. It begins with an unsteady walk, and the legs quickly become paralysed; in some cases the feet are drawn up. This lasts for some days, and then one morning the bird is found dead. A few recover, and after a time seem none the worse for the attack. These chickens are about a fortnight old. They are in a run in Grass; the run is 6 feet by 4 feet, and is changed every two days. The coop for the hen is boarded floor raised 1½ inches from the ground, so is perfectly dry. The food is shelled Oats, barley-meal paste, and a little shredded meal every second or third day.—A. BLAIR.

The feeding and management of your chickens could not be better, with the exception of the coops having wooden floors, and this is probably the cause of the trouble, as chickens are very liable to cramp when kept on wood. Wooden floors when used should always be covered with dry earth or road dust, which should be frequently changed. It is, however, best to have no bottom, but to put the coop on loose dry earth or ashes, 1 inch or 2 inches deep. Possibly you let the chickens out too early in the day, while the Grass is yet damp and cold. When chickens suffer from bad feathering, caused either by the coldness of the season or delicacy of constitution, they require to be lightly fed. Some poultry keepers give their chickens bread soaked in ale once or twice a day in cold weather, and this is a very bad plan. Bread and ale are excellent for young chickens. Weakly chickens are often produced when a hen sits closely upon her eggs. Avoid in-breeding.—S. S. G.

PLANTS AND FLOWERS.

OUTDOOR PLANTS.

SOME APRIL FLOWERS.

A retrospect of the month's display in the early flower garden is always instructive, because there is a reminder to take special notice of those things that have been a success with the view to increase them at the first opportunity. The outdoor flowers of April, then, are naturally the product of perfectly hardy plants, and within the reach of all, either in large or small quantities. So far as the April-flowering shrubs are concerned, the display has been remarkably good, and in all cases where any one particular family or special varieties are wanted together in considerable numbers the effect has been quite up to the average. In the matter of this particular style of planting we do not mean huddling them close together so that they lose their individuality; this is by no means necessary. The plants should stand just clear of each other and be kept so by careful and judicious pruning, close enough so that when viewed from a distance a mass of colour is shown, and not with a perceptible drop between the plants so that a table-like surface is avoided. The *Ribes* family rank among the best of early-flowering shrubs, and some of them seem as if imperfectly known. *R. sanguineum* is, of course, common enough, but it is not the case with a *album* and *atro-rubens*, which flower with equal freedom and make a fine display when planted in large clumps. All the forms strike readily from cuttings and make capital little bushes by the end of the second year. Beautiful white-flowering shrubs in the same season are *Spiraea prunifolia* and *S. Thunbergii*. The foliage of the latter is of a very vivid green, showing off to advantage the sprays of tiny white flowers. A variety of colour is furnished by the *Cydonias* in different shades of scarlet, pink, flesh-colour, and white. Yellow tints have been supplied by *Forsythia suspensa* and *F. viridissima*, two very useful April shrubs. The Daffodil is the early flower of April, and *Barri conspicuus* is one of the best kinds. Other varieties such as the trumpet and star sections may rank higher as individual flowers, but for furnishing a grand display *en masse* commend me to the more named sorts. Flower-stems thrown up from strong selected bulbs were of extraordinary vigour. Common sorts naturalised where the soil and situation have suited them have flowered well. The *Doronicums* have helped to increase the prevailing yellow shades furnished by Daffodils and some of the *Polyanthuses*, and have flowered well. A very fine display of pink tresses of flower, both as to size and quality, is still to be found on the old *Megasea* (*Stavirga*) *cordifolia*. We saw a lot of this the other day at the back of a sloping border raised by a good breadth of a terra-cotta coloured *Polyanthus*, and the effect was very pleasing. The white *Arabis*, the purple *Arabis*, and Tufted *Pansies* (of which

shades of colour also make an effective display when associated with the *Megasea*. We saw the Daffodil was the flower of April, but a thoroughly good strain of *Polyanthus* runs it very close indeed. A north-west border, 200 yards long by 4 feet wide, has been a lovely sight, and furnished us with a wonderful wealth of cut flowers. The plants were arranged as near as possible in colours for the sake of seed-saving, but a general mixture is the more effective. If all the different shades are well mixed together, the result is a beautiful display that can hardly be furnished by any other flower.

TUFTED PANSIES—VALUE OF OLD PLANTS FOR EARLY FLOWERING.

The present season is giving conclusive proof of the value of old plants for making an early spring display, as they are now literally covered with blossoms of the most dainty kind. In the case of the old plants, their culture is of the simplest. The old stools in my case are out back in the autumn to provide cuttings. The thinning-out of the stools for the purpose just alluded to gives more space to those which remain, and they grow strongly. Before the autumn is far advanced it is a good plan to give the beds a good mulching of well-rotted manure, working this well into the crowns of the plants, and also covering the intervening spaces with a liberal dressing. This may seem to be unnecessary with established plants, but it is here where so many err. The mulching feeds the roots, and also affords protection during very severe weather. Then, as the days lengthen the newer growths, which through the bad weather have been protected by the mulching, push their way through the soil, and with the advent of more genial weather the shoots bristle with buds in all stages. As soon as the cool easterly winds have lost their sting, and April showers come, then it is the old plants reward us with a remarkable display of blossoms. Since the second week of April there has indeed been a brave show, and one cannot help wondering why more is not made of the old plants. The late Dr. Stuart, of Chirshill, used to advocate this method of treating the plants, emphasising the fact that some sorts are never seen in their true form until the second and third season of their growth. I heartily support this view, as the results obtained from several of our best tufted kinds, of which the late Dr. Stuart raised so many excellent varieties, have exceeded my expectations. The older type of plant is hardly so well suited to this system of culture as are those represented by such sorts as *Klondyke*, *Blue Gown*, *Floralis*, *King of the Blues*, *Virginius*, *White Empress*, and *Councillor W. Waters*. These plants are now veritable tufts, and studded with their dainty rayless blossoms. These old stools, too, may be kept in excellent condition for a long time by the persistent removal of old and spent blossoms, and also by frequent copious supplies of water in the dry weather. An occasional application of manure-water will impart renewed vigour to the plants, and when they are at the best the younger plants will

take their place. The old stools may be cut back in late June or early July to provide cuttings, which, when rooted, come in well for autumn planting. D. B. C.

VERBENAS.

If these charming flowering plants be employed for the production of special effects in the garden, without doubt they are best when planted in masses of distinct colours. Where employed to furnish mixtures irrespective of colour effects, they are then also very beautiful. There are, however, in the latter case advantages and disadvantages. There is first the fact that *Verbenas* are easily raised from seed, and thus obtained cheaply there is great temptation to put these plants out into beds, with the result that they present a very bizarre appearance, colours being oddly intermixed and the habit of growth of the plants much varied. That such beds have attractions for some persons there can be no doubt, but all the same the effects obtained are not all that can be desired. When *Verbenas* are propagated in sorts or colours and so planted, the mass is usually of a more striking character than when so intermixed. However, in the case of mixed beds it is best to employ propagated plants that can be intermixed in three colours at the most and of even habit of growth. These mixed beds may be found very attractive. It is the case that very careful saving of seed from plants that are remote from others of diverse colours may produce very fair results in evenness of habit and colour, but these can only be obtained by purchasing seed in colour packets. When, however, beds of seedlings are found it is very easy to secure cuttings in the autumn, put them thickly into 6-inch pots, root them in a frame, and keep them clean. Grow all the winter on the top shelf of a greenhouse, and in the early spring they will give scores of cuttings, which may be multiplied almost indefinitely in a few weeks if there be some bottom-heat at command. Thus it is very easy to secure a good stock of selected sorts even from a batch of seedlings.

ROCKETS.

The sweet old *Rocket*, a flower most of us have known from our earliest days, still has its admirers, although it is all too scarce in gardens generally. The time when *Rockets* bloom is a lovely one, for the early summer flowers are gay in great variety. Then especially are the simple roadside cottage plants so bright and sweet, when *Rockets* spring out from carpets of *Pinks* and *Pansies* and lift up their tall spikes to meet the drooping clusters of the *Monthly* or *Maiden's Blush* *Rose*. Happily this flower is much loved by cottagers and it will linger long among them, but in larger gardens we seek it in vain—it is neglected. This neglect arises not from lack of appreciation of its beauty and fragrance, but because, although in every respect a hardy plant, it does not go on growing and flowering year after year. It wants a little special attention, and this can be given at the right time. If left to grow and extend as most

hardy things do, it resents such treatment and soon disappears. It should not be included among the true perennials, as it cannot be treated like them, and yet there are many pretty ways in which it could be grown. The essential thing is to always have young plants. Although occasionally a group may stand a second season, the safe way is to always have a batch of young plants. These may be raised from cuttings, which root readily even in the open ground if shaded from bright sun, whilst another excellent method of keeping up a stock is to take up and divide the plants as soon as they have ceased to bloom, replanting them in another spot. In a well-managed garden there should be a reserve plot where stocks of this and kindred flowers requiring similar treatment might be raised. With such an aid much could be done to reduce the number of tender plants still put out in gardens and show the best flowers of each season in the most perfect way. There are several distinct forms of the double Rocket varying in colour from pure white to lilac, all of them pretty, sweetly scented, and worthy of the best rare and culture.

AQUILEGIA (COLUMBINE).

ALPINE or mountain cove perennials, often beautiful in habit, colour, and in form of flower, widely distributed over the northern and mountain regions of Europe, Asia, and America. Among them may be found great variety in colour—white, rose, buff, blue, and purple, and intermediate shades even in the same flower, the American kinds having yellow, scarlet, and most definite shades of blue flowers. The Columbines, though often taller than most of the plants strictly termed alpine, are true children of the hills. The alpine kinds, living in the high bushy places in the Alps and Pyrenees, and North Asian mountain chains, are among the fairest of all flowers. Climbing the sunny hills of the sierras in California, one meets with a large scarlet Columbine, that has almost the vigour of a Lily, and in the mountains of Utah, and on many others in the Rocky Mountain region, there is the Rocky Mountain Columbine (*A. caerulea*), with its long and slender spurs and lovely cool tints, and there is no family that has a wider share in adorning the mountains. Although our cottage gardens are alive with Columbines in much beauty of colour in early summer, there is some difficulty in cultivating the rarer alpine kinds. They require to be carefully planted in sandy or gritty though moist ground, and in well-drained ledges in the rock-garden, in half-shady positions or northern exposures. Most wild Columbines, however, fail to form enduring tufts in our gardens, and they must be raised from seed as frequently as good seed can be got. It is the alpine character of the lime of many of the Columbines which makes the culture of some of the lovely kinds so difficult, and which causes them to thrive so well in the north of Scotland while they fail in our ordinary dry garden borders. No plants are more capricious; take, for instance, the charming *A. glandulosa*, grown like a weed at Forbes, in Scotland, and so short-lived in most gardens. Nor is this an exception; it is characteristic of all the mountain kinds. The best soil for them is deep, well-drained, rich alluvial loam.

It is probable many of the species are biennial, and that it is well to raise them from seed frequently; and to avoid the results of crossing it is better to get the seed, if we can, from the wild home of the species. The seeds should be sown early in spring, and the young plants pricked out into pans or into an old garden-frame as soon as they are fit to handle, removing them early in August to the borders; select a cloudy day for the work, and give them a little shading for a few days.

Mr. Whittaker, of Moseley, near Derby, has been very successful with both *A. glandulosa* and the blue variety of *A. leptoceras*, and he told Mr. Niven that he grew them in a thoroughly drained, deep, rich, alluvial loam soil; the same were the conditions of Mr. Grigar's success.

Mr. Brockbank speaks hopefully of growing the finer kinds from seed. He says, "I attribute failures to plants sent by nurserymen in very small pots. I believe it will be better

that you can never get up a good stock of *Aquilegias* by purchase. The proper way is to grow your own from seed. Sow in shallow wooden trays, or in pots, and grow the plants out carefully in a cold-frame. When the seedlings are sufficiently large, prick them out into the places wherein you wish them to grow—some in pots and some in the garden—and plant them in various situations, here in the shade and there in the open, so as to have as many chances of success with them as possible. I always plant three plants in a triangle, 4 inches apart, so that any group can readily be taken up and potted if we wish it. Once planted, leave them alone ever afterwards, or if you move them, take up a large ball of earth with them, so as not to loosen the soil about

A white Columbine.

the roots more than can be helped. When the plants have flowered and the seed has ripened, my practice is to gather some for future sowing and to scatter the rest around the plant, raking the soil lightly first, and shaking the soil out of the pots every three or four days. From the seed thus scattered young plants come up by hundreds, often as thick as a mat, and may be transplanted, when suitably grown, into proper situations. In this way I have here abundance of Columbines, and amongst these plenty of *A. glandulosa* self-sown, and as strong and hardy as any. Further details as to culture and position will be found under the various more important kinds.

The late Mr. J. C. Niven, of the Hull Botanic Gardens, one who knew alpine and hardy plants so well, suggests that all the Columbines, except the common one, should be

looked upon as biennials rather than as perennials. The seeds should be sown early in spring, and the young plants pricked out into pans or into an old garden frame as soon as they are fit to handle, removing them early in August to their permanent positions; select a cloudy day for the work, and give them a little artificial shading for a few days. Carry on the same process year after year, the old plants being discarded after flowering. Any attempt at dividing the old roots usually fails. There are, however, instances, especially on the soils and hilly districts, where several of them remain good for years.

A. ALPINA (Alpine Columbine).—A pure alpine plant, widely distributed over the higher parts of the Alps of Europe, the stems from 1 foot to 2 feet high, bearing showy flowers. There is a lovely variety with a white centre to the flower, which, from its colour, is certain to be preferred, and many will say they have not got the "true" plant if they possess only the variety with blue flowers. It does not require any very particular care in culture, but should have a place among the tall plants of the rock garden, and be planted in rather moist but not shady spot in deep, sandy loam, with leaf-soil.

A. BERNINI.—A pretty little alpine, about 1 foot high, with violet-blue flowers, having short knobby spurs.

A. CALIFORNICA (California Columbine). One of the stoniest of the American kinds, its spurs are long, bright orange, more attenuated than in Skinner's Columbine, but to appreciate the full beauty of the flower it must be taken up from its naturally pendulous position. As the beautiful shell-like arrangement of the petals is seen, the bright yellow marginal line gradually shading off into deep orange. The seeds of this kind should be carefully looked after, as having once blossomed the old plants are liable to perish. I have never been disappointed with the seedlings diverging from their parent type in character. This plant thrives best on a deep sandy loam and moist soil. *Syn.*, *A. eximia*, *A. truncata*.

A. CANADENSIS (Canadian Columbine). The flowers of this are smaller than those of the Western American kinds; this, however, is compensated for by the brilliancy of the scarlet colour of the sepals and the bright yellow of the petals. The true *A. canadensis* is a stouter grower, scarcely exceeding 1 foot in height, with sharply notched leaves. Easily raised from seed. There is a yellow form. It is a plant for borders or the shrubbery, but placing here and there among dwarf shrubs and plants in the rougher parts of the rock garden. Writing of this species, Mr. Falconer says: "To see it at its best you should see it among the rocks, where it grows in abundance in our woods and always in high rocky places there it springs from the narrowest chinks of little bush of leaves and flowers, or maybe an earthy mat upon a rock you find a colony of Columbines, Virginian Saxifrages, and pale *Corydalis*; they usually grow together."

A. PURYSANTHA (Golden Columbine). The plant was at first by persons who look at the barren distinctions only erroneously supposed to be a variety of the Rocky Mountain Columbine, and named such by Torrey and Gray. After cultivating the plant, however, for several years, and comparing it in a living state with the Rocky Mountain Columbine (*A. caerulea*), Dr. Gray described it as a new species. The plant comes from a different geographical range, grows taller, flowers nearly a month later, and blooms for two months continuously; these peculiarities added to its full yellow colour, seem to warrant it to rank as a species. Like the Rocky Mountain Columbine, it has a very long and slender spur, often over 2 inches in length. It is quite hardy, and thrives even on the stiff clay soil north of London and enjoys wet, though it is none the less free in more happy situations. It comes true from seed, which is most satisfactory raised under glass, the seedlings being pricked out carefully when young. Attaining a height of 4 feet under good culture, it becomes an important plant for grouping among the shrubs of the rock garden. Should seedlings from it prove crossed with inferior kinds, seed must be obtained from wild plants, which cannot be difficult through the American houses. It would be a great pity if such a distinct, beau-

tiful, and hardy plant should degenerate in our gardens.

A. CERULEA (Rocky Mountain Columbine).—Beautiful and distinct, the spurs of the flower almost as slender as a thread, a couple of inches long, twisted, and with green tips. It is in the blue and white erect flower that the

The Siberian Columbine (*Aquilegia sibirica*).

beauty lies, the effect being even better than in the blue and white form of the alpine Columbine. It is a hardy plant, blooming rather early in summer, and continuing a long time in flower. It grows from 12 inches to 15 inches high, and is worthy of the choicest position in the rock garden. Unlike the Golden Columbine, it is not a true perennial on many soils, though a better report in this respect comes from the cool hill gardens. To get strong healthy plants that will flourish freely, seeds of this kind should be sown annually, and treated after the manner of biennials, as it rarely does well after standing the second year, and in many cases dies out before that time. The flowers are, however, so lovely and so useful for cutting that it is deserving of care to have it in good condition. All the Columbines delight in a deep rich sandy soil, where they can find plenty of moisture below for the roots, and as they make their growth early, the friendly shelter of shrubs or rock to keep off cold cutting winds and frosts is of use.

This is one of the many good plants which deserve a home in the nursery department, so to say. It deserves a choice little bed to itself, from which its lovely flowers could be gathered for the house. The seed is best sown as soon as may be after it is ripe, in cool frames near the glass, or in rough boxes in cool frames. With abundance of fresh seed there will be no difficulty in raising it in fine beds of soil in the open air, protecting the beds from birds or slugs, but the seed is usually too precious to risk in the open air.

What is supposed to be a white variety of this plant is sometimes called

A. IAPPOCENSIS, which was indeed the first name given to the plant.

"M." writing from Utah, says: "Some plants of this species seen in Utah seem to belong to a distinct variety; their colour is not blue, or blue and white, but pure white or yellowish-white. They were flowering in great quantity 10,000 feet above the sea wherever any tiny stream trickled down the mountain slopes, and the flowers at a little distance reminded me more of those of *Eucharis amazonica* than anything else. The plant grows in handsome tufts 2 feet or 3 feet high, the flowers large and broad, and the spurs very long (2 inches at least), with rounded ends at the top."

A. FRAGRANS (Fragrant Columbine).—This is very distinct, growing about 1 foot high, with downy, somewhat clammy leaves, and very free-flowering. The flowers are pale yellow or straw, with short hooked spurs. Himalayas.

A. GLANDULOSA (Glandular Columbine).—A beautiful species, with handsome blue and white flowers, and a tufted habit, flowering in early summer—a fine blue, with the tips of the petals creamy white, the spur curved backwards towards the stalk, the sepals dark blue, large, and nearly oval, with a long footstalk. A native of the Altai Mountains, and one of the best kinds for the rock garden, in well-drained, deep, sunny soil. Increased by seed and by very careful division of the fleshy roots, when the plant is in full leaf. Mr. William Jennings informs me that, if divided when it is at rest, the roots are almost certain to perish—at least, on cold soils.

The Forbes Nurseries, in Morayshire, have long been famed for the successful growth of this plant; it has no special care there, and there is no secret about the culture, which is wholly in the open air. The soil is described as "a rich mellow earth, partaking a little of bog or peat earth, and rather cool and moist than otherwise." It flowers the year after sowing, and when full grown is impatient of removal, but if not transplanted when more than two years old, it continues to flower for at least five or six years, sometimes for more. Those who can get true seed of this fine plant will do well to raise it with care and plant out when very young into well-prepared beds of moist, deep peaty or sandy soil, putting some of the plants in a northern or cool position. It would be well, also, to sow some seeds where the plants are to remain, and in various other ways to try and overcome the difficulty which has hitherto generally attended the culture of this lovely plant. The seeds of other Columbines have a bright perisperm, while those of this species are unbarbarished, arising from little corrugated markings with which the microscope shows them to be covered.

In many cases a different inferior plant bears the name *glandulosa*. Mr. Brockbank says: "I have referred to the original specimen of *A. glandulosa*, sent by Prof. Regel, of the St. Petersburg Botanic Gardens, from the Altai Mountains. It is a different plant from the *A. glandulosa* *jeanla*, being more than twice as tall and in every way more robust. The specimen at Kew is nearly one and a half times the height of the large folio paper in which it is preserved, and the flower measures 4½ inches in diameter. The plants in Kew Gardens are not this variety—the true variety—of *A. glandulosa*, and, as far as I know, it is not to be found with any of our nurserymen."

A. GLAUCA (Grey-leaved Columbine).—A distinct and interesting plant, though not so showy as some of the other kinds. It grows from 18 inches to 2 feet high, with glaucous foliage, the spurs of the flowers being rather short and red, and shading into the pale yellow of the other parts of the flower.

A. SKINNERI (Skinner's Columbine).—A distinct and beautiful kind, the flowers on slender pedicels, the sepals being greenish, the petals small and yellow; the spurs nearly 2 inches long, of a bright orange-red, and attenuated into a slightly incurved club-shaped point, the leaves glaucous, their divisions sharply incised; the flower-stems 18 inches to 2 feet high. Though coming from so far south as Guatemala, owing to the fact that it is met with in the higher mountain districts, it is nearly, if not quite, hardy. Here, again, crossing steps in and too frequently mars its beauty. While the name may be often seen, the plant is rare, nor are the conditions that insure its thriving well known if they exist with us. It is a late bloomer.

A. STUARTI (Stuart's Columbine).—This, a cross between the true *A. glandulosa* and *A. Witmanni*, was raised by the late Dr. Stuart, who tells us that it is, in his opinion, an improved form of *A. glandulosa*, refined in colouring, free-flowering, very large and attractive. It is perfectly hardy, flowers three weeks before any other Columbine, and always comes true from seed. He recommends that a hill be trenched 2 feet deep, with plenty of manure at the bottom, sowing the seed in rows and allowing the seedlings to flower when

they are to stand. The plants may be thinned out to 8 inches apart, allowing 12 inches between the rows. In time the foliage will cover the entire bed, and the plants will produce an abundance of bloom. By top-dressing in the autumn the plants improve in vigour every season, a three-year-old bed being a mass of bloom.

A. VERIDIFLORA (Green Columbine).—A modest and very pretty kind, the Sage-green of the flower and delicate tint of the leaf forming a striking contrast. Out-of-doors in the border the plant may not be noticed, but if a flowering spray or two is cut and placed in a small glass its great beauty of form and colour, too, may be seen. There is a variety of it known as *A. atropurpurea*. The sepals are green, but the petals are deep chocolate. The plant is a strong grower, a native of Siberia, and is the same as Fischer's *A. dalurica*. It has a delicate fragrance, too. It is a rare plant in gardens. Easily raised from seed.

A. VULGARIS (Common Columbine).—The only native Columbine, and as beautiful, I think, as some of the rarer alpine kinds, and no one who has more seen it will readily forget its beauty. It would be most desirable also to select and fix varieties of the Common Columbine of good distinct colours. Being a native of mountain woods and cusses, this may be grouped with good effect in the shrubby part of the rock garden. The best white form of this plant is a beautiful and stately Columbine, which sows itself freely in various positions when once brought into the garden, and looks well wherever it comes. The hybrid forms raised in gardens and much grown and talked of are not so beautiful as this and other wild kinds.

NOTES AND REPLIES.

Passion-flower not blooming.—I have a Passion-flower, bought in a pot three years ago. It was then 2 years old, as evidenced by its having been cut down. It has been planted 2½ years on south aspect, and has for two seasons made good growth, shoots, say, 1½ feet long, and plenty of side growth from old wood. It makes good foliage, and keeps it until mid-winter. It starts in spring rather late—has not moved yet (April 24). The old wood is firm and healthy-looking, and the three 15-foot shoots are more than 1 inch in diameter, but it has never yet shown any sign of flowering. I have cut off the small spray at end of season and slightly shortened main shoots. What can you suggest as to cause of non-flowering? It is planted in good ordinary soil, and would have unlimited run into old brick rubble and mortar and soil, forming a raised terrace to house.—G. W. T., Fulham.

[There is no doubt that the non-flowering of your Passion-flower is due to the roots having

The Common Columbine (*A. vulgaris*) in the wild garden.

obtained an unlimited run into some congenial compost, as is shown by the great length of new shoots made last year. When in proximity to a dwelling-house the roots sometimes find their way into cell drain-pipes, and their

the results are much as you describe. You might, if possible, try curtailing the root-room; but if this cannot be done without difficulty, we should advise leaving it alone for another season, when, if the richness of the soil is partly exhausted, it is very probable that you will this year be rewarded with a crop of blossoms. The only pruning needed will be the removal of any weak and entangled shoots.]

Daffodils, Snowdrops, and Crocus.—Please say how Daffodils, Crocuses, and Snowdrops should be treated after they have flowered? They are in the open, and have not been disturbed for years.—WINDSOR.

[You cannot now do anything beyond developing as much as possible the growth of the year. In the first week in July you may lift the Daffodils and separate the bulbs, which may have become too crowded, and are not giving satisfactory flowers. Dig the ground deeply and thoroughly manure it, or replant the bulbs in a fresh piece of ground that has been well prepared. The others may be treated similarly, and all will benefit by the change. In replanting select a slightly shaded place for the Snowdrops and a more open one for the others. Plant the Daffodils thinly and about 5 inches deep; the other bulbs at about 4 inches deep.]

Lavatera trimestris.—This fine Mallow is not nearly so often seen in our gardens as it deserves to be, and there are not many plants—among hardy perennials, perhaps none—which produce so much effect for so little trouble. Sown in any fairly good soil in an open position, at the end of March or beginning of April, according to the season and the district, it requires no care beyond the routine thinning and a hoeing to kill weeds before the plants cover the ground. The seed is best sown in shallow drills about a foot apart, and for all such work as this there is nothing like the excellent, much-neglected tool—the triangular hoe. Clumps in mixed borders are not amiss, but the effect of a good mass—a group, say, 4 yards or 5 yards square—must be seen to be appreciated. The *Lavatera* grows stoutly, requiring no sticks or tying whatever. The flowers are all charming form, and of a peculiarly fine silky texture, and the colour is a distinct and beautiful pink, with just a tint of the mauve shade of its wild congener—the Mallow of the fields. There is a pure white variety, pretty, but not very distinct; and an "improved" strain, which appears in some catalogues under the name *splendens*, and is really a fine and richly-coloured flower. The *Lavatera* apparently defies the dread fungus of the Malvaceae. In a garden where Hollyhocks are almost destroyed, and where the closely-allied *Malope* suffers badly, it has for years continued perfectly clean and healthy.—G. F. S., *Lywood House, Ardingly, Sussex.*

[With the above note was sent a photograph showing a fine mass, but, unfortunately, it was impossible to reproduce it with any satisfactory results.—Ed.]

ROSES.

ROSES UNDER COOL TREATMENT.

To have Roses in bloom during the latter part of March and early in April there is no better method than growing them without artificial heat, especially when one has a lean to greenhouse. Generally speaking, this is built on the warmest and most sheltered side of a high wall or building. Roses in such a position, even without any further protection, are often very forward at these dates. By pruning them about the first week in January and encouraging the sap to rise steadily and more naturally than when under warmer treatment, together with plenty of air on bright days previous to their having broken into leaf, one may secure the full advantages of such a warm position without danger or harm from late spring frosts, which so often ruin the prospects of Roses upon a warm wall without glass protection. Keen winds seldom have much effect upon a house in this position, as they do not come from the right quarter. Under cool treatment Roses break quite as stoutly as when grown in the open air, and will generally throw equally as good blooms, with the great advantage of better shape and cleanliness than June Roses without glass protection. It is surprising to find a

steady growth without fear of severe checks from night frosts. Roses will bloom fully six weeks to two months earlier, while the foliage comes of better colour and is stouter in texture. As soon as the young growths are from 3 inches to 4 inches long let the borders be well watered and occasionally forked over, taking great care that from this time onwards only what air is absolutely necessary is given, and that early precautions are taken to keep down insect pests.

Under two circumstances only should air be given—when the atmosphere is so fully charged with condensed moisture that the young growths show signs of fogging off or damping, and when the sun shines bright and warm, with scarcely any air moving, thus causing the temperature to rise too high during the middle of the day. With due attention to syringing, together with careful ventilation, mildew and insect pests are easily avoided. When liquid manure is applied with the object of feeding the roots, let it be weak, and give a thorough soaking; small doses of this are not so beneficial. Early in the morning a little manure-water sprinkled on the soil, so that the ammonia may rise and feed the foliage, will be found of great value during bright and trying days, when it is often impossible to admit air without risk of a cold draught. The bright weather of the last few days has made it necessary to afford slight shade; this, however, must be very thin. Do not shade the whole of the glass; a little down the centre of the panes is enough; this, with the bars, will throw sufficient shade and relieve the different portions of the plants as the sun works round.

MILDREW ON ROSES UNDER GLASS.

THERE are some rather sweeping remarks on this subject in your issue for April 26th. It is stated at the outset that "mildew will not attack a thoroughly healthy plant." Such a statement, however, is more readily made than proved. When we see the way that mildew attacks such vigorous weeds as Dandelions, Plantains, Groundsel, Sow Thistles, and the like in the open, while smaller weeds, as Chickweed, Clover, and Landeress, in and around and almost carpeting the other things, remain unaffected, it appears most difficult to determine accurately the causes leading up to any attack, whether under glass or otherwise. As for the Roses under glass, it is stated they "require frequent syringing if they are to be kept clean." This statement I do not at all agree with, and, in fact, I am strongly of opinion that the syringe is largely responsible for the "attacks" of mildew. I did not always think so, but as a grower of several thousand Roses under glass I have not the faintest suspicion of mildew on the one hand, and no syringe has been used in any one of my several Rose-houses. I used, say ten years back, to syringe my Roses occasionally, and I am by no means sure in doing so that I did not supply "that slight check" which is said to render the plants "more susceptible to attack." My Roses are perfectly free of the dreaded pest, and it may certainly be worth considering how much or how little the syringe is responsible for the presence of mildew in those instances where both are known. My Roses get mildew in late or early autumn while in the open, but though pruned after being housed, and one would naturally imagine with the germs of mildew present upon them, the plants never develop it under my treatment indoors. Therefore the absence of mildew would appear to strongly favour the treatment accorded. My paths, too, and, indeed, the entire internal conditions, are kept much drier than in many instances of Rose growing known to me, and where mildew abounds every season. E. J.

FERNS.

FERN-CLAD WALLS.

IN reference to the inquiry in a previous issue respecting information for Fern-clad walls, I venture to offer my experience. Some years ago I had a bare blank brick wall in my vineery, which I determined to make more beautiful. I have, like most others, an accumulation of clinkers on the cinder-heap from the fire. I got a bag of Portland cement, and selected a

lot of large flat pieces, and after soaking them in water I then well syringed the wall, and, having the cement ready mixed, set the gardener to work, and dabbed them in cement and plastered them against the wall, a pair of old driving gloves saving the fingers. In a short time I had the wall covered. I then set to form pockets of the same clinkers as large as might hold a Turnip, and the whole was well set and firm in the course of a couple of days. There is no need of cork, Moss, or wire-netting, all such things tending to harbour snails and woodlice, and I did not put any soil about it, except in the said pockets, in which I put a few Begonias, and perhaps for the sake of colour a scarlet Geranium. It should be borne in mind that there is a fernery through another door, and I found with the occasional syringing that in a couple of months it was covered with greenery. The Fern spores had settled on it, and for the last twenty years it has been a source of beauty and joy. Two or three years ago I had a small lead pipe run along the top and bored a few pin-holes every few inches, that all syringing might be saved. This was done with good effect, and during the last few years I had *Adiantum* fronds 18 inches long. The only trouble I have had—the pretty *Ficus repens* got in, and it got so strong that I had to cut it out, as it was smothering the Ferns. There is no reason why every spare wall may not be utilised in this way, as sun is not needful for Ferns. R. G.

Hale Nook, Warrington.

CHRYSANTHEMUMS.

SIX OF THE TALLER EARLY-FLOWERING JAPANESE SORTS. (IN REPLY TO "C. E. S.")

YOUR request is a rather novel one, as most of our readers ask for selections of dwarf-growing plants. These taller-growing kinds have a special value in that they make an excellent background to a large border, and where large beds and borders are devoted exclusively to these plants, those taller kinds enable the cultivator to group his collection all the more effectively. Any time between the first week in May and the close of the month is the time to plant them out. You cannot do better than plant the following sorts:—

NOTRE DAME.—This is a free-flowering silvery-pink kind. The plant, too, has a bushy habit. Height about 4 feet. In flower during the whole of October, and later when the weather is not severe.

MARQUIS DE MONTMORT.—Although this variety was introduced quite a decade since, it is now rarely seen. The colour is silvery mauve, and the plant is a profuse bloomer. Height about 4 feet. In flower during October.

MILLE. SABATIER.—This is a good companion to the first mentioned variety, and possesses a free growing habit. It is a profuse-flowering sort, developing blossoms of a purplish-crimson colour. Height about 4 feet. In flower from middle of October onwards.

WHITE QUINTUS.—In this variety we have a pure white sport from the popular early-flowering sort, O. J. Quintus. The blossoms are of beautiful form, with pretty twisted florets. The plant blooms all the way up the stem from the axils of the leaves. Habit bushy and sturdy. Height between 3 feet and 4 feet. In flower October.

GLOIRE DE MEZIN.—Some ten years ago this was thought much of. Little has been heard of it in recent years, yet it may be classed as one of the best of the October-flowering kinds. It comes into bloom during the second week of that month. The colour may be described as chestnut red, and the flowers, which are much larger than in the majority of early sorts, are also freely developed. Height about 4 feet.

CORAL QUEEN.—This is another sort which has been some little time in commerce, and still valued for its distinct and pleasing coral-coloured blossoms. Like most of the taller-growing sorts, its habit is not so compact and bushy as is desired. Height about 4 feet. In flower from middle of September onwards. E. G.

TREES AND SHRUBS.

PIERIS (ANDROMEDA).

This at one time was known as Andromeda, but there is in reality only one Andromeda—viz., *Andromeda polifolia* (Moorwort), a native of Britain and other parts of Northern Europe, as well as the northern United States and Canada.

In growing the varieties of *Pieris* the leading points to be observed are selecting a cool, moist position, and not necessarily a peaty soil always free from lime, as naturally heavy soils can be made to suit them by deep trenching, and adding plenty of leaf soil, with, towards the top, a little peat. Being slow-growing and compact-rooting they cause little

trouble in pruning or moving. The beds in which they grow suit many species of Liliaceae, which thrive well planted between the shrubs. The best-known varieties of *Pieris* are:

P. floribunda.—A native of the United States, and forming a neat, compact evergreen bush. The racemes, which form in October and do not open until the following spring, are terminal and branching, as may be seen by our illustration, and carry numerous white flowers.

P. japonica.—In seaside and west-country gardens this is a valuable shrub, the leaves when young of a reddish colour, changing with age to a deep green. The flowers, which are porcelain white, are borne in a cluster of erect branching racemes terminating the shoots. The flower is pendulous and almost globular.

P. japonica is without doubt one of the finest

evergreen shrubs we have, its graceful habit and handsome leafage alone entitling it to a place in our gardens. It is of slow growth, and always keeps in a shapely form, thus requiring very little pruning. The flowers, borne at and near the ends of the shoots in clusters of drooping racemes which are each from 2 inches to 5 inches long, are pitcher shaped and white. It comes, as its name implies, from Japan.

Other kinds of less importance from a garden point of view are: *P. Mariana*, from N. America. The leaves of this, which turn a brilliant red before falling, are said to be poisonous to animals. Then we have *P. nitida*, a native of Florida and the southern United States, and *P. ovalifolia*, in which the flowers are pinky-white and showy, like the leaves, which when young are redish-purple.

the ball of earth with the roots—but incline the growth quite to the wall at the surface level of the soil. Plant quite firmly and treat the soil about the plant, but not to the extent of smashing the ball of earth. Water thoroughly to soak the whole of the soil when planting is completed. It may be necessary, and certainly very helpful, to water once a week for some time to come and so insure a good start. The *Roses* named are good, but in either south or east are not so lasting, and the blooms of W. A. Richardson are apt to come pale. But you may plant them in company with the *Aboretum* or with *Clematis Jackmani*, which is a strong doer and free-flowering. Another excellent plant as a climber is *Clematis montana*, with snow white blossoms in May. This plant will require some training, like the other kind and the *Roses*. *Roses* and *Clematis* together constitute quite a happy mixture, and virtually give two crops of bloom from the same area in one season. But the *Clematis* should not be planted with the *Ampelopsis*. All the plants should be obtained established in pots; it is now too late to plant the *Roses* from open ground.]

Evergreen shrubs for fence.—I shall be much obliged if you will give me your advice on the following matter: I have lately put up a fence lined of old railway sleepers and wire netting, dividing off from a field a piece of ground in front of my house, which I am turning into a flower garden and pleasure ground. I have planted on this fence a number of *Roses* and *Clematis*, *Honeysuckle*, and *Sweet Peas*, which, doubtless, will in a short time cover the fence well for the summer months. I am afraid, however, that the fence will be very bare in winter, and shall be glad to have your advice as to what plants would be best to use, so that the fence may be as attractive as possible all the year round? The sleepers, when bare, are unsightly, and so they would want to be well covered. The fence in question is about 50 yards long, and about 10 yards of it at one end are rather shaded by trees.—C. J. L.

[As your fence is already furnished with climbing plants, it is difficult to see how you can use subjects of an evergreen character to take off the bare appearance in winter, as if you plant a screen of shrubs they will in the summer shut out your flowering plants from view. If you have sufficient space you might plant an evergreen alternately with the existing deciduous plants. For the shaded portion *Ivy* commend themselves, and of these there are so many beautiful and distinct varieties that a good selection is, when in a thriving state, always attractive. Other plants available for a similar purpose are *Cotoneaster microphylla*, *Crataegus Pyracantha* (the Fire Thorn), whose berries in winter form such a brilliant feature, *Escallonia macrantha*, *Garrya elliptica*, *Passiflora caerulea* (blue), and *Passiflora Constance Elliot* (white), while *Pyrus* or *Cydonia japonica*, though deciduous, commences to expand its bright-coloured blossoms by mid-winter.]

The Flowering Currant (*Ribes*).—Were this plant less common than it is, it would receive more attention, for nothing in early spring in our gardens can excel it as regards attractiveness. The ordinary form is well known, but there are some varieties that merit more extended cultivation, the chief of which is the double-flowered, which not only differs in being double and of a deeper shade of colour, but has the desirable property of expanding a week or so later than the ordinary form, thus considerably prolonging the season of the Flowering Currant. Remarkably deep-tinted forms, almost a blood-red, are those called *Billardieri* and *atro-rubens*. Continental varieties are very desirable on account of their rich tints. Then there are a few lighter-coloured varieties, and one named *albida* is almost a white, the flowers only being suffused with a delicate blush. Another called *pallida* is of a somewhat deeper shade than the last. The yellow Flowering or Buffalo Currant (*R. aureum*) deserves extended cultivation. It has large flowers of a rich yellow, which appear about the end of April or beginning of May;

Pieris (Andromeda) japonica. From a photograph by G. A. Champion.

NOTES AND REPLIES.

Climbers for house.—I have just moved into another house with a small garden, but two sides of the house are rather bare, and I am anxious to cover them with climbers. Can you give me any ideas as to what is best for the purpose? I have been recommended *Ampelopsis Vitifolia* and *Roses* (W. A. Richardson and *Gloire de Dijon*). Is it too late to transplant these from a nursery? The two sides I want to cover are the east and south. What will grow on them so as to make a good covering, and how should they be planted?—S. H. R.

The *Ampelopsis Veitchi* will do quite well for either east or south wall, and another good kind, also self-clinging, is *Ampelopsis muralis*. The latter is rather quicker and more free in growth, and by obtaining good plants in pots may be put out at any time now. In planting, prepare by digging a hole 2 feet wide and deep, and fill with good soil, to which add quite one-third well-decayed manure. Do not fix the plant nearer to the wall than 6 inches—that is,

trouble in pruning or moving. The beds in which they grow suit many species of Liliaceae, which thrive well planted between the shrubs. The best-known varieties of *Pieris* are:

P. floribunda.—A native of the United States, and forming a neat, compact evergreen bush. The racemes, which form in October and do not open until the following spring, are terminal and branching, as may be seen by our illustration, and carry numerous white flowers.

P. japonica.—In seaside and west-country gardens this is a valuable shrub, the leaves when young of a reddish colour, changing with age to a deep green. The flowers, which are porcelain white, are borne in a cluster of erect branching racemes terminating the shoots. The flower is pendulous and almost globular.

P. japonica is without doubt one of the finest

GO

the leaves, also, are smaller, more deeply lobed, and paler green in colour. The Flowering Currants are really an important group of shrubs, and deserve the best attention, and, instead of being crammed in the usual shrubbery mixture, should be grouped by themselves.

INDOOR PLANTS.

* * * THREE USEFUL WINTER-FLOWERING PLANTS.

REGINIA CLERIE DE LOURAIN.—Anyone contemplating a display should at once make a start. A few old plants that are just their best make excellent stock. Cut back the old flower-stems to their base, give the plant a short rest in a cool house and keep them on the dry side. In about a fortnight they should be brought into the stove or any house with a night temperature of 60 degs. to 65 degs., with a rise to 70 degs. or 75 degs. in the daytime. If kept moderately moist at the root they soon throw up new growth from the base. Take off the cuttings with a heel, or at a good joint, and insert either round the edge of a 4-inch pot or singly in thumb-pots, according to the strength of the cuttings, using a light compost with a liberal sprinkling of silver-sand. Water and place in a propagating-case, at the warmest and shallowest end of the stove. If they cannot be placed out of reach of the sun they must be shaded by some means. A sheet or two of newspaper will suffice, as this can be put on or taken off as required. Bottom-heat is not absolutely essential where the above temperature can be maintained. Keep the case closed, except for a short period every morning, when the light should be tilted an inch or so in let off the superfluous moisture. In from fifteen to twenty days they will be sufficiently rooted to be taken out of the case and gradually inured to the light and air of the house, and finally placed on a shelf close to the glass with a slight shade. As soon as the little pots are full of roots the cuttings will require a shift into larger pots, using a 3-inch or a 4-inch pot, according to the strength of the plant. The grower must bear in mind that at no period do the plants like a big shift. The compost at this and subsequent pottings should consist of equal parts good fibrous loam, leaf-soil, and rotted stable-manure, with a liberal amount of silver-sand. But lightly, place them back on the shelf, and carefully attend to watering. The final shift into a 6-inch pot will be large enough for most requirements, and if all has gone well with them, pinching them about twice during growth, they will show a nice lot of bloom by Christmas.

ERANthis JACQUINIFLORA is a graceful and effective plant when in full bloom; and yet how seldom does one see it well grown, considering the time it lasts in bloom? I have had plants in flower over three months. Half-a-dozen old plants placed in heat are ample to raise a stock of young plants. When the young shoots are from 2½ inches to 3 inches long they should be taken off with a heel and placed in thumb pots in sandy soil. In the same case with the *Reginias* they will soon take root. As soon as ever they are fit take them out and place on a shelf close to the glass. But as they become fit, about two shifts being sufficient during the season, the last shift into a 6-inch pot. Pinch them once or twice during growth to induce them to throw out branches. The compost for these should be two parts fibrous loam, one part leaf-soil, with enough sand to keep the whole porous. A good dash of old mortar-rubble, crushed fine and well mixed, for the final potting is beneficial.

PHENSETIA PULCHERRIMA.—Assuming one has a few old plants to begin with, these, after resting, should be cut back to within a foot or 1½ inches of the base, and at once started in heat. By keeping them fairly moist at the root and syringing the stems once or twice daily, they will soon break into new growth. When the young growths are from 2½ inches to 3 inches long, cut them off with a heel, and at once plunge the heel of the cutting into a pot of fine sand or charcoal dust to check the bleeding. Small pots should be filled with light soil, and one edged with silver-sand, allowing

a little silver-sand to trickle down to the base of the cutting. Press the soil firmly around them, water, and place in the above-mentioned case, or one similar, as here again bottom-heat is not absolutely necessary. It is important that as little time as possible is allowed to elapse from the taking of the cuttings to placing them in the case, as more they are allowed to flag they are a long time before they recover. It all has gone well they should be fit to take out of the case in from twenty to twenty-five days; here again one must be taken that the change does not cause them to flag too much. They should be stood in the shallowest part of the house for a day or two, afterwards placing on a shelf close to the glass. A 4-inch pot for the first shift, finally placing them into 6-inch, and some of the strongest into 8-inch pots. A good compost for these is three parts good fibrous loam, one part leaf-soil, half a part decayed cow-manure, with a liberal dash of silver-sand. Well mix the whole, and put firmly. During all stages of growth the plants should be stood as near the roof glass as possible to keep them short-jointed. About the second week in August the main batch should be hardened off in a cooler house or pit, where they should have the full benefit of sun and air to thoroughly ripen the wood, or otherwise poor, thin flowers will result. About the end of September or a little later, if the weather continues favourable, they must be brought back into a warmer house, and eventually into the store to get them into flower by Christmas.

W. DUNN.

The Gardens, Pimlico, Aberystwyth.

CINERARIAS.

The month of May is a good date to sow seed for an early winter display, making a second sowing at the end of June for a late spring batch. Pans 10 inches or 12 inches across are the most suitable, filling them to within an inch or so with fine soil of a sandy nature, principally loam and leaf-soil, afterwards placing a little rough material over the cracks. Sow thinly, just covering the seed, and place in a cool-pit or frame, with a sheet of glass over, and shade from the sun. If the soil is on the dry side it is best to water a few hours previous to sowing, then no more water should be required until germination has taken place. Remove the glass when the seedlings are through, place near the glass, still shading from the sun, as *Cinerarias* delight in a fair amount of shade and moisture. Before too crowded prick off into pans or boxes of similar soil, 2 inches or 3 inches asunder, keeping close for a couple of days or so until restarted, when plenty of air must be given. A light drawing overhead with the syringe two or three times daily will benefit the little plants. Place into 4-inch pots before the foliage gets drawn, carefully lifting the plants with as many roots and as much soil as possible, returning them to a cold frame on a northern aspect resting on an ash bottom. The soil for this first potting need not be quite so fine. To one bushel of fibrous loam add one peck of leaf-soil, a 5-inch potful of soot, a 6-inch potful of bone-meal, and enough sand to keep the whole porous. Water through a rose can, and keep a bit close and shaded until re-established, when afford full ventilation, removing the lights during fine nights. A strict look-out must be kept, as green-fly, thrips, and the Marguerite leaf-miner, or maggot, are all enemies to this plant, and soon cause disfigurement to the foliage if once established. Fumigating with nicotine will destroy the two former, and hand picking is the only remedy for the maggot. Shift into 6-inch and 7-inch pots when fit for potting, which will be large enough for them to flower in. Keep the plants frequently turned round, and allow plenty of space between each, for if the foliage gets drawn it detracts greatly from the appearance of the plant. As soon as the pots are full of roots, a little weak liquid-manure water from the cowshed, or clear soot-water, once a week, will be of benefit to the plants.

Usually the plants may be kept in cold-pits or frames well into November if carefully matted up at night, but care is necessary that the foliage does not decay owing to dampness. When removed to the greenhouse, open a window to the heat as much as possible, and the plants

plants are kept the better and less liable to insects. It is a wise plan to fumigate every fortnight or so. The large-flowered varieties are still admired, though *cruenta* and *stellata* are worthy of a place when lofty houses have to be kept gay, and I find these, though sown at the same time, take longer to come into bloom than the larger flowered ones, thus carrying the display well into May. The free-branching habit of the *cruenta* and *stellata* forms makes them more suitable for grouping than the large flowered kinds, the many shades of colour, too, adding greatly to their beauty.

J. M. B.

NOTES AND REPLIES.

Phyllocaeti failing.—I have a collection of *Phyllocaeti*. I find a good many are turning a reddish-brown in the leaf, some are shriveling. Can you give me the cause and the remedy? They are well attended to, and are watered plenty of light and air. They are potted in a mixture of loam; charcoal, broken brick, dried cow-dung, leaf-mould, sand, and a little peat.—CARRIE.

[Your note does not show a weak place in the treatment of your *Phyllocaeti*, and we can only suggest that they may have been kept too cold and moist at the roots during the winter, at all events, that was the cause of some plants that we inspected lately behaving as yours have done. On examination most of the roots were found to be decayed, hence we advised them to be shaken clear of the old soil and repotted in some good, sweet compost, keeping them afterwards rather closer and warmer. They already present an improved appearance. *Phyllocaeti* do best in a structure where the temperature in winter falls but little below 50 degs., and very little water is at that time needed. If on examination the roots of your plants are found to be dead, shaking clear of the old soil and repotting are certainly the best remedy. After potting be careful not to over-water, but a slight bedewing from a syringe is on bright days very beneficial.]

Plants for greenhouse.—I have a small greenhouse, about 15 feet by 9 feet, without heat, which has proved itself a splendid one for *Maréchal Niel* Roses. The north side is a brick wall to the sloping eaves, and the south side is glass. Should the Roses be grown up the north side, and what can I grow on the south side? Will Tomatoes do well? If so, what kind?—S. H. R.

[You are fortunate in possessing a greenhouse that will accommodate that magnificent *Rose Maréchal Niel*, and we would not hamper it with anything else. Rather would we develop the *Rose* and fill the house therewith, and so make it a feature. The *Rose* will certainly require to be so trained that the shoots get fully ripened by exposure to the sun, as upon this depends so much of the flowering next year. It will, therefore, depend on the size of your plant as to what you can accommodate besides, and with the *Rose*-shoots trained near to the roof on one side, Tomatoes may be grown on the other. Do not allow the plants to run wild and so overrun the place that the *Rose* will suffer. Six plants may be grown, keeping them to a single stem, not stopping until they nearly reach the roof. By planting on the south side you may train them up the rafters and not stop them at all. Keep all lateral eyes pinched out or rubbed out as they form. Challenger is a good kind and free. You had best procure the plants in pots, as having no heat, you cannot get a long season of fruiting, and perhaps it will be best when three or four trusses of fruit are set to stop all further growth and cut off the rest.]

Growing Caladiums.—I am growing a good many *Caladiums* from tubers, and also from seed purchased abroad. I should like to get my own seed, but although many of my plants have flowered, not one has yet produced any seed. I should be much obliged if you could tell me the reason. Should they be artificially fertilized? If so, in the ordinary way? In no book I have the subject mentioned. Childs, of New York, has made a great fuss about a flowering *Caladium*, which he calls the "New Century." I ordered several, and as they were sent in a growing state, they arrived, of course, dead, except one, which, by careful nursing, I have pulled through. I am very doubtful, however, whether it is worth the trouble, for I do not believe it is a *Caladium* at all. I cannot speak with absolute certainty, because I have not yet seen it in flower, but the leaves are like those of a *Utricularia* in shape and colour (glossy green), and the habit of growth is the same. Do you know anything about this so-called *Caladium*?—B. C. DAVENPORT.

[It is necessary to artificially fertilise the *Caladium* blossoms (which can, however, be readily done) in order to ensure seeds. An item of great importance is to maintain a dry atmosphere at that period, as from the shape of the spathe moisture is apt to collect there, and thus deprive the pollen of its potency.

By watching the flowers after development you will see that the low portion of the spadix has numerous protuberances, which are really the female organs of the blossom. Immediately above these the pollen will soon make its appearance, all that is necessary being to

often used, and flower well. *Thunbergia alata*, an annual plant with orange-coloured blossoms, can be raised from seed, and its long, trailing shoots will not be without flowers during the summer. The blue flowers of the looser-growing forms of *Lobelia* are also very pretty, while a common British plant, the Creeping-Jenny (*Lysimachia nummularia*), bears its golden blossoms profusely. Of variegated-leaved plants beside the Ivy-leaved Pelargonium *L. Elegante*, you may use *Nepeta glehmanni variegata* and *Messembryanthemum confilium variegatum*. Presuming the baskets are of wire, and that is the material generally used, they must, in the first place, be lined with large, closely-woven flakes of Moss, if they can be obtained. In some districts these are easily got, but failing them thin turves with the Grassy sides outwards form effective substitutes. Considerable care must be taken in lining the basket, as upon this a good deal of the future success or otherwise depends. Being finished, it will be of cup-like form, and into which your plants may be disposed at will and planted therein. In planting take care to keep those of pronounced drooping habit around the

edges, and do not pile up the soil above the lining material, otherwise it will wash off when watering. Ordinary potting compost, such as a mixture of two parts loam to one part each of leaf-mould and well-decayed manure, with a little sand, is very suitable for all the plants above mentioned. After the basket is planted, a little fluky Moss pugged over the top is an advantage, as it keeps the soil from being washed away, while a good plan is, when filled, to allow it to stand down for a week or two before hanging

have cut off some of the extra branches, and have repotted it (it is in a very large pot), but it looks as bad as ever. Can you advise me on the subject?—S. G.

[Your Indiarubber-plant is in all probability too far gone to restore to health—in fact, the shrivelling of the shoots and the leaves lying off would indicate that the roots, and very likely the base of the main stem, are dead. It is difficult to say with certainty what is the cause, but our experience is that in nearly every case that comes under our notice the soil is kept too wet, particularly during the winter months, while the pot is often considerably larger than the plant really needs, and when this is the case, even if but seldom watered, the soil is apt to get too wet. The fact of your plant failing about a month ago would indicate that the mischief was done in the winter, for some little time would elapse before the damage was noticeable. We can only advise you to throw away your old plant and start again with a young and vigorous one—if possible, a plant that has been grown in a cool structure, for in some nurseries where Indiarubber plants are grown in quantity they are pushed on in considerable heat in order to attain a saleable size as soon as possible, and consequently they are apt to sicken when removed to a cooler place. To keep an Indiarubber-plant in health the leaves should be sponged frequently, and enough water given to keep the soil fairly moist, but by no means in a saturated state. When water is needed give sufficient to wet the ball of earth thoroughly, but in no way allow any of it to remain in the pan or saucer in which the pot may be stood. If repotting is needed, do it in the months of April or May, using a mixture of equal parts of loam and peat, with a good dash of sand. See that the pot is effectually drained with broken crocks.]

Lilium auratum not starting.—In March I bought and potted a quantity of *Lilium auratum* bulbs, and then put the pots in a box, covering them with wet ashes. I have had them in a cellar till now. On examining them I see no signs of growth or of root. Kindly say in your paper if I ought still to keep them in the cellar, or put them in a heated greenhouse or cold-frame?—J. S.

[You have done quite right in potting the bulbs and plunging them in the box, but we think you erred in covering with "wet ashes." This may be no detriment, and will depend on the condition of the bulbs. There is no time

Pteris floribunda. (See page 134.)

remove it with a camel's-hair brush to these protuberances below. A part of the spathe may be cut off if it is in the way. In a dry atmosphere some of the blossoms will fertilise themselves, but to ensure success the better way is to use the brush. We have seen the advertisement of the New Century Caladium, but not the plant itself. The illustration at once struck us as representing one of the *Colocasias*, some of which have fragrant blossoms, a feature claimed for the Century. They are nearly related to the *Caladiums*, one species, indeed (*esculentum*), being sometimes regarded as a *Colocasia* and sometimes as a *Caladium*, but, of course, wholly removed in every way from the beautiful-folaged varieties of *Caladium* grown in gardens, which are the progeny of *Caladium bicolor*.]

Plants for baskets.—Will you kindly let me know (1), which are the best plants to have in a hanging-basket (in the open) to make the best and longest show of bloom (to include Ivy-leaved Geraniums), with a fair amount of fancy or variegated foliage and trailers! (2), The best way of making up a basket for planting, and also the compost used?—W. J. CURRER.

[You have a considerable choice of subjects that will do well in hanging-baskets in the open, and keep up a display of flowers during the summer months. Ivy-leaved Pelargoniums thrive under such treatment, and especial mention must be made of the double-flowered forms—*Souvenir de Charles Turner*, carmine; and *Mme. Croisse*, salmon-pink. A variety known as *L. Elegante* has the leaves broadly edged with white, which under exposure to the sun becomes suffused with pink. This is the best variegated-leaved kind for hanging-baskets. The flowers are single, loose, and whitish in colour. *Tropaeolums*, too, of the different kinds make good basket-plants that will resist drought better than some subjects. *Petunias* also are very attractive, particularly the single-flowered forms, as they are not so readily injured by wind as the double kinds. *Begonias* of the tuberous-rooted section also do well in this way, not little seedling plants, but good-sized tubers, at least as large as a penny. For the centre of the basket *Fuchsias* of a free-branching habit of growth, or brightly-colored *Zonal Pelargoniums*, bright-eyed

it in its place, as the plants will be by then taking possession of the new soil.]

Failure of Indiarubber plant.—I have an Indiarubber-plant, well grown, and in a large pot. It did not get on well in London, so I brought it down to the country in March, since when, up to a month ago, it has done very well. Now, however, it is drooping, the soil is shrivelling, and the leaves falling

lost yet, as some bulbs take a long time to start either root or top growth. It is always best, however, if the bulbs are quite sound, to use soil only just moist—certainly nothing like wet soil should be used and then covering with ashes of the same degree of moisture and richness as the soil in which the bulbs were

Pteris formosa (in a Cornish garden). (See page 111.)

may be needed till the growth was well above the ashes. The cellar is quite a good place, and in the dark, uniform coolness of such the bulbs will be safe, even if they do not so early start into growth. It frequently happens that but few roots are produced from the base of the bulbs in this Lily, and none are seen until the top growth is made and the roots appear on the stems. Such as these are not destined to make a permanent success, and, indeed, will not be a success in the first year, unless these stem-roots are encouraged by covering them carefully with good soil, for on these depends the flowering, and with this performed the bulb perishes, because, no basal roots having been formed, no fresh bulb centre is formed either. No harm will ensue if you carefully take out a bulb for examination, and if sound the bulbs will be quite safe in the cellar till growth appears.]

ROOM AND WINDOW.

CUT FLOWERS IN THE HOUSE.

THE arrangement of cut-flowers in the house appears to be, in a general sense, very little understood. Very often flowers individually of the greatest beauty are wedged together in a glass or vase so tightly as to be almost unrecognisable, and no regard whatever is paid to harmony of colour or to suitable foliage for forming a setting to the flowers. Wherever possible, the flowers should be arranged with their own foliage, and only one kind ought to be used in the filling of the glasses or vases. In the vase here figured the Narcissi look well arranged among the sprays of Laurel, and the flowers being few in number and lightly and carelessly arranged, are seen to the best advantage, which is not the case when they are luddled up together, as is often the case.

PLANTS AND FLOWERS IN THE HOUSE.

PLANTS IN POTS.—With the more congenial weather there will be far less need of fires; in fact, it will be good policy to dispense with them entirely, save in the largest of rooms. In consequence of this, more plants will in some cases be needed; more particularly is this found to occur where the fireplaces have to be filled. Such positions are not in any sense suitable for plants, being oftentimes far removed from the light. It is also a good policy, as far as the plants are concerned, to keep the chimney ventilators closed where these exist. With the tiled fireplaces and curved margins in place of the fenders, as now in use, it is an easier matter to make a good effect with such arrangements than it used to be, as the pots are not so much seen, a saving of the smallest plants being made. To start with, in such groupings, or indeed at all times, the plants chosen should be of a persistent or enduring character. Of Ferns, for instance, such as *Asplenium heidum* and *A. bulbiferum* should be chosen; whilst of the Pteris family, *P. tremula* and *P. cretica* are two of the hardiest. The *Lustreas* and *Doodias* are all suitable selections. Only the very hardiest of the Palms should be used at present; it is a pity to spoil well-grown *Kentias* by using them too soon. *Phoenix dactylifera* and *P. reclinata*, with *Seafortnia elegans*, are each calculated to stand well, more particularly the two former. Of other fine-foliaged plants, every possible use should be made of the *Aspidistra*, the green-leaved form being the hardier of the two. *Aralia Sieboldi* will also stand well; so will *Phormium tenax*. Turning to the flowering subjects, *Spiraea japonica* will be found one of the best, provided it be freely watered. *Dielytra spectabilis* is also a suitable plant. Dwarf Indian *Azaleas* look very well, but it is a pity to use them in such unfavourable positions. By aiming at the use of plants which are of no material moment after they have flowered, the results in the long run as regards the supply will be found more satisfactory. To half kill a plant and then have to expend additional labour in its restoration to health is not at all a good policy. *Eulalia japonica variegata* and *E. japonica zebrina* are excellent for the purpose.

so are *Asparagus plumosus* and *A. tenuissimus*, whilst of other flowering plants *Primula obconca* would serve a good turn, as well as late *Cinerarias*, both of which can be thrown away when of no further use.

CUT FLOWERS.—With the rapid advance of spring we have a wealth of hardy flowers from which to select; these will in a great measure relieve the demand upon plants grown under glass. It is either a mistake or a lack of appreciation of the beautiful that fails to recognise the immense utility of hardy flowers in a cut state. The earliest possible use should be made of them; by so doing, not only is the choice so much the more varied, but it affords an opportunity of turning the room under glass to a better account. The early deciduous *Magnolias* are over and gone for the season; they have, however, done good service as cut flowers. *Pyrus japonica* has lasted out well, and now we have later species from which to choose, as *P. sinensis* and *P. spectabilis*. The *Lilacs*, too, are earlier than usual this spring. *Scilla campanulata* claims notice as one of the most beautiful of its race for use in floral arrangements. If the spikes be pulled instead of cut, they can be had of greater length, whilst even with only a few flowers expanded

quite early in the morning or just before night-fall; if cut in the middle of the day with the sun shining brightly, it cannot be expected that they will keep well.

GROWER.

FLOWERS AND PLANTS IN ROOMS.

A bowl filled with Sweet Brier and single Post's *Narcissus* fills the room with sweetness, and though there are in the same room a large *Gardenia* and a bouquet of *Stephanotis*, the Sweet Brier is the winner in the competition of sweet smells. A bunch of Parrot Tulips, some all yellow, some yellow lamed with scarlet, are in a tall Dutch jar; they are of high decorative value, brilliant in colour, and fine in form, with their richly fringed and jagged petals tossed about in a lawless fashion, thrown across one another or flung right open; some have stalks standing stiffly upright, but oftentimes about in a way that makes it easy to dispose them gracefully over the edge of the jar. An upright glass holds a large bunch of *Narcissus biflorus* with pale green foliage of the yellow Day Lily. Alpine *Auriculas* are valuable as cut flowers, lasting in good condition quite a week, and retaining their sweetness to the end. From their varieties of colour many beautiful com-

An arrangement of *Narcissi* and Laurel shoots.

each spike will continue to develop up to the extremity. Before this variety is over, the other forms of it, as *S. campanulata alba* (very beautiful) and *S. campanulata rosea*, will be in flower, each doing excellent service. The common Bluebell even is not by any means to be despised. The later kinds of *Ballifolias* are as serviceable as the earlier ones, most of them being quite distinct. It would be an easy matter to multiply instances of hardy flowers which may be turned to a good account. Their use is even further emphasised when having to cut a quantity of flowers to send to a distance, far surpassing those from under glass, on the whole, for safety in travelling. From under glass cut *Roses* will be amongst the best and choicest flowers. Of these, William Allen Richardson is valuable. It is one of the very best, but, unlike many climbers, it will bear free pruning when once a large plant has been obtained. Its lasting qualities do not seem to be fully known. It soon develops from the bud stage to the expanded bloom, but it then lasts so remarkably well—better than many other *Roses*; it fades from the rich apricot shade, it is true, but the petals do not drop prematurely. *Roses* from under glass should now be cut

binations may be made, such as pale yellow, delicate lilac and white, and lilac blotched with purple; another of tawny and copper-coloured with crimson and deep maroon, observing that it is generally best to keep those together that have the same coloured central ring, whether white or yellow. A white china basket has blue *Pansies*, pale and dark, from vigorous border sorts; the shoots of flowers and leaves are cut whole, and hold themselves much better than any arrangement of the flowers and foliage cut separately. With the *Pansies* are some long-stalked single blooms of *Clematis montana*, and a well-chosen spray of *Clematis* with short-stalked flower-winds round the handle and droops over the front of the basket. A storm-broken branch of *Apple* gives material for filling a brass dish 15 inches across; the twigs of wide open flowers are in a large group towards the centre and one side, the rest is of the rosy buds and half-open flowers; between and among the blossoms, not stiffly arranged, but as if growing up here and there, are shoots of the highly-polished and brilliant green young leaves of *Ivy*. An oval silver basket is arranged with pale pink and rosy Indian *Azaleas* and *Clematis*. These *Azaleas* are still among our most valuable cut plants.

GARDEN PESTS AND FRIENDS.

Is the Globe-flower poisonous?—I enclose some of the Globe-flower (Troilus europaeus), and would be much obliged if you could tell me if the young shoots are poisonous? Nearly every spring I lose a sheep, always in the same field, and only in this same field does the Globe-flower grow in two large damp places. I think the young shoots must poison the sheep, but before fencing, digging it out, would like to know if such is the case?—U. P. S.

Many of the Ranunculaceae (the family to which the Globes belongs) are poisonous that I quite expect the Globes may be. I have never heard of its injuring sheep or cattle before; but it is by no means a common plant in woods, so that the young shoots may be poisonous, though not generally considered to be so.—G. S. S.]

Bees in bank.—Will you kindly tell me the name of the wild bees? I found thousands of them on a warm, sandy bank at Ottersham, in Surrey, each one burrowing a hole in the sand. The bank for many yards was full of them. I have never seen so many solitary bees, and they are not, in one locality.—HENRY W. POOCK.

The name of the little wild bees which you find so plentiful burrowing into a sandy bank is *Andrena fulviventris*. They are solitary bees, as each makes its own nest without assistance from others, but at the same time they are gregarious to a certain extent, as they are generally found in numbers together, the situation which suits one being equally congenial for others. They fill the cells in their burrows with honey and pollen as food for their grubs.—G. S. S.]

Plague of earwigs (*R. Humphries*).—The only way to get rid of earwigs is to trap them, unless you could shut up a rooin and are sulphur in it, which is probably not practicable. As they fly well, there is no means of expunging them out of the house but by closing the windows or doors. Earwigs may be trapped in crumpled-up sheets of newspaper, loosely folded cloths, the hollow stems of plants, such as Bean or Sunflower stalks, or small Bamboos, they are said to be very fond of hear and made. You might try smearing a sheet of newspaper with some, and then crumpling it up and placing it where the insects are. In the morning open the traps over a basin of strong water, or water that has a little kerosene oil floating on the top.

The St. Mark's-fly.—Please tell me whether the grub is the same as those mentioned in your paper March 20, and which turn into St. Mark's-fly, or are they another grub in their earliest stage? Some of our men are full of them, but they have had manure on all the winter.—MOLLSKROPP.

The grubs you sent are, I believe, those of the St. Mark's-fly, but I cannot be quite sure, they had become chrysalides before they reached me, and in this condition it is impossible to be quite certain of the species, they certainly are not the grubs of the cockle. The manure would have no effect on the grubs, except keeping them warmer than they would otherwise have been.—G. S. S.]

The Holly-fly.—A large Holly-tree is badly infested by these grubs—see enclosed leaves. Kindly suggest what had best be done to destroy them? The shrub is otherwise healthy, growing well, and with plenty of bloom.—DOE ATCK.

Your Holly is attacked by the grubs of the Holly-fly (*Phytomyza aquifolia*). It is a very difficult pest to deal with, as no insecticide can reach the grubs, safely enclosed as they are between the skins of the leaves, which are very hard and stiff, and the transformations of the insect are all undergone within the leaf. The flies lay their eggs under the skin of the leaves in May or June. If the exact time of the appearance of the flies could be found out it might be possible to prevent them from laying their eggs by spraying the leaves with paraffin solution, taking care to spray both sides. The trees would have to be kept under the influence of the wash for several days. The only other remedy I can suggest is picking off the infested leaves and burning them, which would be almost as difficult to accomplish as spraying.—G. S. S.]

Codlin-moth destroying Pear-bloom.—Kindly tell me what the larva is which is infesting my Pear blossoms, and what I am to do to prevent the loss of my whole crop? The Pear-tree is Marie Louise, situated on the wall of my dwelling house, age about 30 years. For the last 10 years I have suffered more or less from the same. I think, Dipterous larva, specimens of which I have enclosed. I have tried various remedies. I have covered away the soil round the roots, burnt it, and treated it with fresh earth, treating it as one would a raspberry-bush. This year I tried spraying the trees with Bordeaux-mixture, the recipe for which I obtained from your pages. Nothing seems of any avail, and I enclose you for information and advice.—W. H. A. POKKAND.

the enterpillars of the Codlin-moth (*Carpocapsa pomonella*), in a very juvenile condition. Spray the tree at once with 3 oz. of Paris-green, an equal quantity, bulk for bulk, of fresh lime, well mixed in 50 gallons of water. This mixture should be kept well stirred, as the Paris-green is very heavy, and soon sinks to the bottom. When this is the case part of the mixture is too weak and the rest too strong. It should be applied with a syringe or garden-engine with a spray nozzle, so that it should settle on the blossoms like a fine mist. When any of the infested Pears fall prematurely, as they are likely to do, they should at once be picked up and destroyed. In the case of standard trees, it is very useful to tie hay-bands or fobbed strips of canvas, etc., round the stems near the ground, so that the water-pillars, when they leave the fallen fruit or let themselves down to the ground from those which have not fallen, reach the stem and begin to climb up it in search of a sheltered place in which to become chrysalides, soon find just what they want. This would hardly be of much use in your case, as the caterpillars would probably find shelter in some crevices in the wall or behind the branches where they touch the wall. You might spray the tree and wall in the course of the winter with a caustic wash, made as follows: Put 1 lb. of caustic soda into half a pailful of water, to this add 1/2 lb. of pearlash, stir until all is dissolved, then add enough water to make 10 gallons; lastly, add 10 oz. of soft-soap which has been dissolved in a little hot water, and mix all thoroughly. This is a very caustic mixture, and will kill any insect life that it comes into contact with, but it will also ruin any clothes it touches, and if it gets on to the skin it should immediately be wiped off.—G. S. S.]

FRUIT.

VINE LEAVES SCALDED.

Could you kindly tell me what is wrong with the enclosed Vine leaf? This year the Vines have grown well and there is a good crop of grapes, but several of the Vine leaves have gone like the one sent.—F. W.

[To all appearance this is a bad case of scalding. The leaves received are somewhat thin, and the smaller one seems to have been pressing rather hard against the glass at some time. Far too many Vines are grown much closer up to the glass than is good for them. There ought always to be a clear space between the leaves and the glass, and instead of the wires being strained from 6 inches to 12 inches from the latter (10 inches being perhaps a fair average of what is to be met with), they ought to be not less than 15 inches, and where there is sufficient head room in the house 18 inches from the glass should be the distance. When the leaves are close up to the glass, or press against it, which is far worse, a few minutes' neglect in ventilating may, and often does, mean the ruin of many of them. Especially is this the case when the temperature during the night has been low, and not sufficient fire-heat employed to prevent stagnation of the atmosphere. Leaves in a dry state do not scald so quickly as those that are wet, whether the moisture be due to syringing, exhalation, or condensation. The sudden rise of heat from, say, about 60 degs. to nearer 100 degs.—and this may take place close up to the roof without those in charge being aware how hot the house has become where the leaves are—sometimes results in scalding, or if the leaves press against the glass they are literally parboiled. Some houses, owing to their construction, more especially as regards the quality of glass used and the close fit of same, require to be ventilated earlier and more carefully than others, and the position of the rinery has also to be taken into consideration. We should advise "F. G." if he has not previously done so, to keep a little heat in the hot-water-pipes during the night, and if a chink of top air be put on the last thing at night, the requisite buoyancy of atmosphere will be maintained and moisture prevented from collecting on the leaves. On bright mornings more air should be given before the heat rises to 75 degs., and be gradually increased. When air is given thus early, sudden dashes of cold air are guarded against and the need the ventilators be opened so widely as would be necessary when

late morning ventilation is resorted to. This treatment would probably be followed by a thickening of the leaves and a general improvement in the health of the Vines.]

NEW WOOD ON OLD FRUIT-TREES.

I THINK there is nothing more disheartening to owners of gardens than to go on year after year cultivating fruit-trees or bushes on what is supposed to be the most approved plan, and to find that there is little or no return for all the labour and expense they have bestowed on their trees. This feeling is often aggravated by seeing trees of the same varieties baled with fruit in their neighbour's garden, where hardly any trouble is taken with them. In the end we are forced to admit that a good deal of energy has been wasted on our trees in the shape of pinching and pruning, and that if more natural growth had been allowed for heavier crops of fruit would have been obtained. In looking round several gardens last summer I observed many Pear-trees that had originally been closely pruned small-trees, but from getting into a barren state they had been allowed to grow into pyramids high above the walls. When I saw them the long branches had bent right down on to the top of the wall with the weight of fruit. There can be no question that over-restriction of the growth, especially of wall or espalier-trained trees, has had more to do with inducing barren and worthless trees than all other causes put together. In my early days I have often had to prune off all the fore-right shoots of Pear and other wall-trees that were simply perfect as far as form and training went, but as fruit-producing trees they were worthless. Young trees, with no old and worn-out wood, are favoured by market-growers. The old closely cropped-in trees are giving place to more naturally grown specimens. But one need not rush to the opposite extreme and give up pruning altogether, for, except in the case of large standard orchard-trees, that course soon produces only second-rate fruit. With wall-trained, espalier, pyramid, or bush-trees the one thing to keep in view is a constant succession of young fruitful wood, to get which it is obvious that a portion of old wood must be removed to make room for it. I had that it is better to do this removal by degrees than to have any fixed season or date for the work. Now that there is a wonderful display of bloom on all sorts of fruit-trees, both trained and untrained, is an excellent time to take out any old or worn-out shoots, to give the rigorous young wood room to extend. Just after the crop is set is the best of all times for thinning-out any useless wood, for one can then insure a crop for the current year, and at the same time provide space for training in the wood that will carry next year's crop. New wood is not only necessary on outdoor fruit-trees, but especially on old Vines, for if young rods are taken up from the base every year to replace the ones that carry this year's crop, the spring of labour is enormous, and the results in weight of crop quite doubled. JAMES GROOM.

Goquat.

Liquid manure for fruit-trees.

Many people who have orchards might get double the quantity of fruit and of an infinitely better quality by pouring the liquid from the farmyard around their Apple-trees instead of letting it go to waste. House sewage is most valuable for the purpose, but where the orchard is Grass covered it should be diluted considerably, or it will kill the Grass. In an orchard which I know, and where the trees are very old and showing signs of exhaustion, house sewage was applied during the winter, with the result that fine healthy growth and abundance of large fruit were produced the next season. Farmers in particular who have plenty of horse and cow urine might preserve their orchard-trees in a fruitful and profitable condition by its judicious annual use, and that, too, without a great deal of labour. All orchards are further improved by being surface-tanned previous to the liquid being applied. This admits air and warmth the following spring, and induces the roots to come to the surface. Old trees of hardy fruit-trees, also Vines, would be equally benefited by the same treatment. If, however, the forest in which

the latter are growing is composed of strong loam or is at a low elevation, injury might ensue from the winter use of liquid-manure.

VEGETABLES.

EARLY POTATO GROWING.

SPROUTING IN BOXES BEFORE PLANTING.

Another important matter is the size of the sets, and this falls naturally to be considered with the method of sprouting in boxes or trays before planting. This method is the most powerful agent in hastening on the early Potato crop. It is now in universal use in England and Scotland wherever early crops are grown, and it has so much to commend it that in many districts it has been adopted for the late crop also. The system, however, is not well known in Ireland, and some minute description is desirable. The box or tray is 24 inches long, 12 inches wide, and 3 inches deep. The corner pieces are 7 inches in height, and strong, so that the boxes can rest on the top of each other when piled for winter storage. There is a cross handle for carrying, which is tenoned into the side pieces, and the whole forms a light, handy, and durable utensil, which, with ordinary care, will last for years. These boxes are not at all expensive, the cost being 30s. per 100 completed, or a little over 3d. each. Each box holds about 20 lb.; speaking roughly, it takes about six boxes to 1 cwt. The seed Potatoes are filled into the boxes until they are level with the sides. No earth is mixed with them, and no water applied to them. No particular care is taken to have the eyes set upwards; the Potatoes are simply poured indiscriminately into the boxes, and left to huddle as Nature suggests. If large sets are used they will be one deep in the boxes; but, if of a smaller size, they may be two or three deep. This does not matter; the sprouts find their way up through the interstices. When the boxes are filled, they are piled up one on the other to any height it may be found convenient. There is no way in which seed can be kept more safely or stored in smaller compass, and it can be examined at will and overhauled at convenience, should that be found necessary. The rule in Scotland is to fill the boxes in October, and by February the sprout is long enough. In Ireland, where the winter temperature is much higher, the trouble will probably be, not to get the sprouts sufficiently long, but to keep them from growing too long. Therefore, the end of November would be a good date to fill the boxes.

Two inches is a good workable length of sprout; if much longer they are apt to wriggle about and break off unless very gingerly handled. The length of sprout, however, cannot always be regulated, and sometimes they may be so long as to be touching the box above. There is no actual harm in this, but it is inconvenient and should be avoided if possible. The best way to check growth is to expose the boxes to light and air. When growth is desired, exclude all light. Exposure for some time before planting is necessary in any case, in order to toughen the sprout and enable it to be handled with impunity. When the boxes emerge from darkness the sprouts are very white and tender, just as they are in a pit, but after a few days' exposure they become quite hardy and do not readily break. At this stage another most valuable use of the box becomes apparent—viz., whenever exposure takes place it can be seen at once whether the stock is pure. Among the multiplicity of varieties there are scarcely two which have the same colour of stem and habit of growth. Thus Puritan has a white and spindly stem, which becomes greenish on exposure; Early Regent has a short, sturdy stem, which becomes bright red; Maincrop becomes purple. In this way it is always possible to eliminate the "rogues" before planting, although it is a very troublesome and often wasteful operation. Regarding

THE SIZE OF THE SETS.

Irish growers as a rule prefer large tubers, which can be cut. That is in the main sound judgment, but in the cultivation of early Potatoes some modification of this opinion has to be observed. Many of the first early varieties

are not suitable for cutting. Puritan, for instance, is a most risky Potato to cut. It does well enough under perfectly normal conditions, but where the plant suffers any check from frost, cold winds, or drought, and is thereby cast back upon the resources of the set, it rarely does well. The flesh is very soft and soon rots away to the skin, so that there is no vigour left to start on a new growth in May, should that be needed, and the plant becomes sickly and infertile. Something has to be risked if seed be scarce and dear, but, on the whole, it is better if Puritan and that soft class be not cut. Boxing almost precludes cutting. Of course, it can be done after exposure has rendered the sprouts strong enough to handle. But it is a tedious and expensive process, and is often rendered futile by the fact that the tuber has grown only from the first intention, and has produced only one shoot, or, if two, so close together that a knife cannot be inserted between them. If it is desired to persist in cutting, the seed should be boxed early, and when it has sent out a tiny shoot, that should be broken off, and the Potatoes will then bud from several eyes. The ideal size for boxing would be about 1½-inch riddle, but Potatoes cannot be made to order, and buyers have often a limited choice. It would be a mistake to discard a known and reliable stock because of uneven size, and take in preference an unknown lot on account of its uniformity. Crops grown from seconds appear to come earlier to maturity than those grown from large sets, but the yield is lighter. The reason of this is that the plant is not so vigorous and ceases to grow to top sooner, and consequently takes to tuberizing. Therefore if a grower is in a favoured position in point of earliness, can raise for the very earliest market, and can command the first and highest price, he need not hesitate to plant seconds. If, however, he is not so favourably placed for earliness, and has to take a secondary place in the matter of price, he has then to rely on a heavy crop for results, and that is more secure with large sets. A safe practice would be to buy "good and ware" dressed over 1½ inches, and when boxing separate the "seconds" from the "ware," and put them in a different set of boxes. Plant the small ones close, say, 10 inches to 11 inches apart, and the large ones wider apart, say, 18 inches to 20 inches. The large sets will mark themselves to a drill throughout the whole season, will give a heavier crop, and be a few days later. "Seed and ware" is a size much easier bought, as a rule, than uniformly sorted seconds. A thing to be avoided is seconds grown from seconds. Nothing deteriorates a stock so quickly as that. After the boxes have been filled and housed, care has to be taken that they suffer no damage from frost. It takes a good deal of frost to injure Potatoes in boxes, provided there are no apertures through which cold winds can reach them, and it is extremely unlikely that any risk will be incurred from this cause in those parts of Ireland where the industry will be attempted. But if there should be a protracted and very hard frost it would be necessary to apply some heat. That is not difficult. For a small house an oil-stove would suffice, and for a larger house a slow combustion stove suits very well. No vent or chimney is required if coke is used for fuel, as there is no flame to cause danger from fire, and the fumes do no harm. House accommodation is not always easily provided. Boxes are frequently piled in the rafters of stables and cowsheds, and they do quite well in such places. In the south and west of Ireland they would be safe outside, if some old sacking were tacked over them to turn the wind, and a straw stack built over the whole.

ADVANTAGES OF BOXING SEED.

Although the main purpose of boxing is to secure an earlier crop, the system has besides many other advantages. One of these is that the seed is better preserved. A crop of early Potatoes, designed for seed and raised in August or September and stored in pits, must necessarily grow to a considerable extent before spring. In handling, these growths have to be broken off, and the sets thereby suffer seriously in vigour, and, consequently, the plant is robustness. Moreover, the first intention from which Nature intended the plant to grow is

lost. All this mischief is obviated by boxing. Another great advantage is that the farmer need not hurry to plant his ground in spring while the land is in a wet and undesirable condition. The seed is doing its work better in the boxes than it possibly could in such adverse circumstances, and the land is not soured by unseasonable working. It is often urged against the boxing system that it is too expensive. That is not the case. The initial cost of boxes is not more than 30s. per acre, and seed is stored more cheaply in boxes than in pits. The cost of planting is not appreciably greater than ordinary methods. An exp-er-er, planting 12 inches to 15 inches wide will cover a statute acre per day.

MANURING.

It is now an established fact that farmyard dung alone, no matter how heavy the dressing, will not produce the maximum crop of the best quality. Dung should be supplemented by a suitable artificial fertiliser. Especially for early Potatoes is this imperative. The best crops are often got after lea without any dung at all, and there are fields in Ayrshire which have borne crops of early Potatoes for three years consecutively, and which have received no dung during that period. These instances are mentioned to show what can be done on land in good heart without dung; not by any means to encourage its disuse, but rather to give a view to illustrate the power of other fertilisers. For early Potatoes a manure of quick action should be used, as it has only three months in which to do its work. A manure with an analysis of nitrogen, 8 per cent., potash, 4 to 5 per cent.; and soluble phosphates, 18 to 20 per cent., and compounded from the most soluble materials, would be a safe manure to use. The formula being strong in nitrogen would not be suitable for rank-growing late varieties, but early Potatoes have usually very small tops, and can stand a good deal of forcing. The quantity to apply will vary according to the condition of the land and the quantity of dung applied. With a dressing of 2½ tons per statute acre of dung, 6 cwt. of artificial would be enough. Where no dung is used, double the quantity of artificial manure is required. The time to apply this is before planting, and before the sets are put down. It is not a good plan to top-dress Potatoes, and force them by fits and starts, as might be done with a forage crop or Cabbage. To do so exposes the tuber to second growths, and tends to injure both shape and quality. No injury to the sets occurs from contact with the manure. Artificial manure may be sown either by hand or by a machine; it does not matter provided the distribution is done evenly.

TILLAGE OPERATIONS

do not differ materially from those observed with late Potatoes. Of course, the crop has to be expedited all through, so that the land may be available for planting at the first favourable opportunity in spring. Where the land is to be cleaned should be done in autumn, and should be applied in autumn or winter. Whatever the method of tillage observed may be, whether the Potatoes are planted in drills or lazy beds—care should be taken that the sets are planted at an equal depth, so as to avoid having "laggard" plants. If planted in drills, the fresh opened drill should not be disturbed by passing a loaded cart along the drills. In such event the soft newly-dressed drills are badly foot-stepped and wheel-marbled, and the sets which fall into such indentations must inevitably be later. Laggard plants are the ruin of an early crop. The grower has to choose between sacrificing them or his market for the ones that are ready to raise. The expedient should therefore be used to prevent this undesirable state of matters.

MARKETING

The early crop requires no little forethought. In districts where large quantities are produced merchants appear and provide all the labour necessary for packing and conveying to market. But with an industry in its infancy grower will need to look ahead and find out how to get their produce cut he quickly disposed of. The cities and large towns of Ireland can no longer absorb a large quantity, but a considerable surplus must find its way somehow to English markets. Green Potatoes will not carry

they must be packed either in baskets or barrels. As a rule, commission salesmen are willing to supply these, and if they are filled and firmly packed on the top with fresh, green stalks and laced securely, they will carry quite safely by rail or steamer.

M. G. WALLACE.

OPEN-AIR TOMATOES.

Many err in sowing the seeds of plants intended for planting against outside walls too early; consequently, the plants become pot-bound and the wood hard long before the weather is fit for transplanting them. Where fear of this evil exists it will be well to pot the plants on, as they will soon root round the balls, and may then safely be kept in frames or a cool house for another fortnight if need be. Have a small batch of plants brought on in advance of the main lot, and finally potted into, say, 10-inch pots with a view to sinking them into the border of a south wall. This in warm districts may be done at the end of this month, and if after the cavity has been taken out a good thickness of rotten manure is placed on the bottom and the holes in the pots made much larger, the roots will soon push through the bottom, and, taking advantage of the rich food provided, will grow away freely and fruit well. The pots should be sunk just below the ground level, so that a liberal mulch of hart manure can be given in order to conserve the moisture and also to encourage surface roots. Bearing in mind the root-restriction this batch is subject to, water must always be supplied with a liberal hand, and when sufficient fruit is set, the leading growths must be pinched, all side laterals being likewise kept off. Of course, some method of protection must be devised, or cutting winds and even late frosts may cripple the plants. A very good plan is to put wide boards on either side of them, and to place some Yew or Laurel-boughs in front. These admit sufficient sun-heat and light, and yet screen the growth from harm. These plants which are to form the principal batch for outdoor work, and which will not be planted out until the beginning of June, must be gradually hardened off in frames, being fully exposed on fine sunny days, as in the case of the above-named lot. If any signs of exhaustion show themselves a good surface-dressing of hoar and artificial manure must be given. It is well to prepare the stations under walls for Tomatoes some time before actual planting, so as to give them an opportunity of setting. There is then less fear of excessive evaporation, and the plants generally go away better than when put into newly-disturbed soil. When preparing, add a little good loamy soil and rotten manure, mixing it thoroughly and making it firm. On the plants that are to be plunged a few fruits may set while in the frames. These should not be removed, as they will swell off in spite of the removal to an outdoor temperature, and, ripening extra early, prove most useful, especially where no indoor Tomatoes are grown.

NOTES AND REPLIES.

Planting Asparagus.—In most gardens this may now be done. It should be borne in mind that however much trouble and expense the preparation of the new beds may have cost, failure and disappointment must ensue unless due care is bestowed on the seedlings at planting time. Careless planting has much to answer for in the many failures in growing this vegetable. The rootlets are of such a delicate character that exposure to cutting winds for a few minutes, or even to hot sun, may destroy them. When the roots have to be sent from a nursery, arrangements should be made for packing them in damp Moss or some such material. When home-grown roots are employed, the matter of transplanting is much easier. A calm and, if possible, dull day should be chosen for the job, and, presuming that the beds are ready, the soil will now be loose and firm and need not be trodden. Some still prefer the old-fashioned 4-foot beds, but unless the soil is retentive and cold it is not necessary to raise them, above the ordinary level. Capital results may be had from planting single rows, allowing a distance of 2 feet from plant to plant and a 2½-foot alley between

For the first year or two this space can be utilised for Lettuces. Lift only a few plants at a time, sprinkling the roots and planting carefully with a small handfork. If the compost is not of the best description, work in a little fine loam and leaf-mould amongst and around the roots. Sink the crowns just beneath the surface, and if the young growths have pushed, draw a little soil over them to protect from frost until somewhat hardened. Nothing more will be needed except keeping down weeds until growth is a foot or 18 inches high, when small sticks should be placed to each plant and the shoots secured thereto, as high winds are very liable to loosen them at the base and sometimes snap them off. This precaution is not necessary the second year. On hot soils, if the summer should be dry, a slight mulch of leaf-mould will be beneficial.

Cucumbers dying off.—Can you kindly tell me what is the cause of my Cucumbers dying off? I sowed the seeds in small pots on a mild hot-bed. They came up all right, and, when they were making the third leaf, they died off. I kept them just moist after they got up. I bought two plants which looked strong. I planted them carefully on a bed made of stable-manure and leaves, the temperature of the bed being about 75 degs. when the frame was closed, but I gave plenty of air in the daytime. Will you tell me the best way to grow the 'S. H. KING'.

[You have erred in starting so early with frame Cucumbers. By your statement as to temperature when the frame is closed, it is clear the heat must have been too low during the sharp weather a short time since, particularly while the cold winds were prevalent. March and April are two very treacherous months for seedling Cucumbers, and the least check quickly brings bad results. You have now two ways open to you, and either should succeed now the days are longer and more sunlight prevails. If the frame still retains a temperature of 75 degs., sow three or four seeds in the mound of soil in the frame. This mound should be 8 inches high at least, and the seeds just inserted in the soil by making a small hole with the finger. Cover the seeds with fine soil or silver-sand. The frame should be kept moist by slightly damping with the syringe, but otherwise, if the mound of soil is fairly moist, no actual watering will be necessary. As soon as the seedlings appear dust a little air-slaked lime about the mound of earth, and with the appearance of the first rough leaf add a little rather rough soil to the stems of the plants. This will at once increase root action, and the plants, being raised in a rather cool temperature, should be proof against the fungoid attacks that kill so many young plants in the early part of the year. Plants so raised suffer little, and there is no check from the potting or transference to the frame. You had best rely on damping the mound with lukewarm water rather than watering the plants in the usual way, because plants raised on the mound of soil as suggested quickly send roots in all directions. Another way is to sow a half-dozen seeds in a 5-inch pot, covering with sand in place of soil, and potting them singly as soon as the first rough leaf is formed. Or you may sow the seeds singly as before, only half filling the pots with soil, and earthing up as soon as the stem has reached 4 inches long. Unless this is done and done quickly, the young plant will perish slowly because of the absence of the main roots that should follow the first fibrous roots from the seed. This, coupled with the many fluctuations of temperature, and the lowness of night temperatures particularly, are chiefly responsible for failures in the early part of the year. Frequently the sudden collapse of the young plants is due to a late damping down, or too much overhead moisture generally, being followed by a rather cold night. In such a case superfluous moisture is very harmful. Where a minimum temperature of 70 degs. cannot be maintained it is better to forego damping either the plants or the house later than 4 p.m. during March and April, and in these months the plants will bear with impunity a lower temperature if a comparatively dry condition of the atmosphere exists.]

As many of the most interesting notes and articles in "GARDENING" from the very beginning have come from its readers, we offer each week a copy of the latest edition of either "STOVE AND GREENHOUSE PLANTS," or "THE ENGLISH FLOWER GARDEN," to the sender of the most useful or interesting letter or short article published in the present issue, which will be marked thus:

GARDEN WORK.

Conservatory.—Barnard Andrea alba and other late-flowering Azaleas will require a good deal of water now, and well-rooted plants may have a little Clay's fertiliser or some other stimulant in the water. Where the old-fashioned show and fancy Pelargoniums are well grown they make splendid groups now. All these and most other flowering plants will last longer if covered with a thin shade during bright weather. Of course the syringe cannot be used much among such flowering plants, but there must be some amount of moisture in the atmosphere on bright sunny days in April and May. This can be supplied by dumping the floors and stages—if there are stages in the house—in the middle of the day, or whenever the sun is hot and the atmosphere appears dry. Herbaceous Spiraeas will require watering two or three times a day, unless they can stand on a damp bottom in the shade. Very charming groups can be made with Spiraeas and Maiden-hair Ferns in a cool, shady part of the conservatory. It is a pleasure sometimes to turn from the bright, glowing masses of Azaleas and Pelargoniums to the green and white Spiraeas and Ferns. Streptosolen Jamesoni is a rather showy plant just now. It has a somewhat gawky habit unless pinched freely when young, but it is so different from most things in flower just now that it is worth a little pains to make it good. It roots freely from cuttings of the young shoots, and it succeeds planted out in a light position and trained against a wall or pillar in the greenhouse. The Lachenalia, or Cape Cowslips, are pretty basket plants now. The bulbs are inserted rather thickly in wire baskets, all round the base and sides of the basket, and well mossed in, and the bulbs are planted even more thickly on the top. The bulbs may be brought on in ainery till the flowers appear, and then moved to the conservatory.

Stove.—Climbers add much to the beauty and interest of the stove, and many of them may be useful exhibition and decorative plants. Well-grown specimens of Allamanda, Bougainvillea, Clerodendron Balfourii, Stephanotis floribunda, and Dipladenia always carry weight in a collection, and the flowers of most of them are useful for cutting. To induce them to flower freely the growth must be made in the full light, and for this purpose, if grown in pots with the intention of afterwards training round a balloon or any other kind of trellis, the young shoots during the growing season are led up to the glass and kept in the light till the flower-buds are visible, when they are taken down and twined round the trellis. Jasminum gracillimum is a sweet thing to have a plant or two of. To have plenty of flowers for cutting plant out in a bed of loam and peat, freely mixed with sand and crushed charcoal. All the above may be helped with liquid-manure when the flower-buds are formed. Cissus discolor is rather out of date, but is useful for hanging-baskets. Cuttings of the firm shoots strike freely in sandy peat in brisk bottom-heat. The Indian variegated Grass (Panicum variegatum) is another useful draping plant. It has a pretty effect in rather small pots along the edges of the stages, and is one of the best plants for baskets, and the sprays when cut are useful to mix with flowers.

Early Peach-house.—The early fruits will now be putting on colour, and every fruit should be fully exposed. All overhanging leaves should be thrust on one side; a leaf or two may be removed if necessary to give full exposure. Very free ventilation is necessary to obtain good flavour, and though the roots must always remain moist it is quite possible to injure the flavour by over-watering or giving strong stimulants during the finishing. Peaches will take a good deal of nourishment after stoning, but this should be discontinued during the flavouring and finishing processes. Red-spider sometimes gives trouble in early houses, especially if the borders have been dry during the early stages of growth. When the roof is a movable one, it is a great advantage to take off the lights when the wood is thoroughly ripe, so that the autumn rains may find out the dry spots (if any) in the border.

Early Melons.—Bottom-heat is essential to the well-doing of Melons till the fruit is

pretty well finished, and though it may be possible to have the beds in which Melons are growing too dry, yet this is not likely to happen during the ripening process. Heavy, retentive soil is the best for Melons. Firm growth and substantial foliage are pretty well proof against the attacks of red spider, and it is important that the old leaves of Melons remain green and healthy till the fruits are ripe. The time to feed Melons, if stimulants are given, is after the fruits are set until they begin to ripen. There is very little difficulty in getting a crop to set when the growth is firmly limited up by planting in heavy loam. Cucumbers are often planted in soil of too light a character to obtain the best results economically. When grown in a fairly heavy soil there is not half the labour in syringing and watering.

Cold frames.—By the time this appears in type bedding plants which have been well hardened by exposure may stand in some temporary shelters in the open air, and the frames can then be filled with Cucumbers, Melons, Tomatoes, and Capsicums. Frames will also be required for growing on Cyclamens, Cinerarias, Primulas. Young seedling Ferns of the greenhouse kinds do better on ashes in cold frames in summer than in houses. Aralias, Grevilleas, and other greenhouse fine-folaged plants give less trouble and do better in cold frames.

Window plants.—There will be plenty of blossoms now on the Pelargoniums. What is commonly termed the Geranium family are favourites with cottagers. The old Oak-leaved Geranium is a sweet thing in a cottage window. Fuchsias now coming into bloom, and should be helped with a little stimulant. Balsams, if not already up, should be sown at once; they may be easily kept dwarf and sturdily by keeping them in the window in a light position. Ferns and Palms may be repotted if necessary now. Never expose them to hot sunshine.

Outdoor garden.—Finish planting Gladioli; even the late-flowering Brunelleyensis will be better in the ground now. Thin out hardy annuals in showery weather, though in a general way transplanting annuals at this season is not always a success, yet I have had grand masses of Godetias and several other things from transplanted plants. It means a little more labour in watering, etc. Among shrubs suitable for massing *Genista præcox* is just now very lovely. *Berberis stenophylla* is also good, as is also *Berberis Aquifolium*. The last grows well under trees. The *Tamarix* is a pretty grouping plant, looking well on the edge of the lawn, jutting out from the edge of the shrubbery. In breaking away from the common bedding arrangements, use might be made of *Clematis Jackmani superba*, an improvement upon *Jackmani*. Let it break from the ground at any rate for the first two seasons. This, of course, means cutting down annually. If it is necessary to prune Evergreens, such as the small Conifers, Evergreen Oaks, etc., the best time to do it is just before growth commences. The same remark applies to Hollies and Yews, but if either Hollies or Yews are cut hard back at any time the work should be done in March, early in the month.

Fruit garden.—Though it is too early to leave wall-trees which have been protected uncovered at night, if the covers are heavy curtains they should be drawn on one side, and the trees fully exposed on fine days. Disbudding, if not already taken in hand, should begin now, and the disbudder should have the Tobacco-powder handy, so that every suspicious-looking spot for insects may be thoroughly dealt with. It is promptness which saves so much trouble in the future. Disbudding is usually done tentatively, so as not to unduly expose the young fruit. Sometimes some of the shoots from which shelter can be obtained are pinched for the time being, to prevent further expansion, and are removed later when there is no need of shelter. The Plums and Cherries are very full of blossoms. The Pears, too, in many gardens in our district are very promising, but Apples are not everywhere so full, but doubtless if the blossoms stand there will be a crop. The greatest loss to Apple-growers is due to the Codlin-moth, and every means should be taken for its eradication. Many people, I notice, are lime-washing the stems of their trees, but that

though useful, is not sufficient. Grease-lime is put on in autumn; any useful; spraying as well with an insecticide is beneficial as soon as the Apples are set.

Vegetable garden.—Prick out Celery enough to meet every requirement. Two inches of good loamy soil on a layer of old manure is the best bed for young Celery plants, as then every plant can be lifted with a ball, and, if well watered when put into the trenches, will start away at once. Plant out the earliest Brussels Sprouts. Cauliflowers planted for summer will do well on north borders. Lettuces, also, will come fast enough there. West borders are also useful for salad-plants. This is one of the advantages of the walled garden; there are so many different aspects and climates, and the practical man takes advantage of them for bringing on various things in hot summers. The sites may be prepared for Vegetable Marrows and ridge Cucumbers. The best preparation is half a barrowful to each hill of equal parts loam and old manure. The loam steadies the growth and the plants grow sturdily and the fruits set better; of course, the time for planting is not just yet, unless headlights and warm coverings can be spared. Runner and dwarf Kidney Beans may be planted freely now, and this is the time to sow Marrow Peas for August. If no provision has been made for a supply of such tender annual herbs as Basil and Sweet Marjoram, sow now in a warm, sheltered spot. Usually these are sown under glass and planted out at the end of May. E. HOBBAY.

THE COMING WEEK'S WORK.

Extracts from a Gardener's Diary.

May 5th.—Beds of Tulips and other spring-flowering plants are very bright now. As it will be June before the bulk of the spring flowers will be over, Begonias and other things will be shifted into 5-inch pots for the latest beds. A heap of prepared compost lies ready for top-dressing the beds. Something short that the roots can work into at once we find better than manure. The cleared rubbish supplies a good deal of this. Tied up Lettuces; even Cabbage Lettuces are the better for being tied up to blanch.

May 6th.—We are still doing a little propagating, chiefly new things being dealt with now. Some of the newer Heliotropes have very large flowers, and more stock is wanted. Balsams and the plume-flowered *Celosias* were used for massing last season successfully, and will be repeated. The Balsams were planted thinly over a groundwork of *Harrison's Musk*, as both require plenty of moisture. Planted out border *Chrysanthemums*, *Marie Masse*, *Mytchett White*, *Queen of the Earlies* (yellow), and *Raycroft Scarlet* are in groups.

May 7th.—Pricked off more real Celery on prepared bed. Sowed seeds of various hardy perennials. Looked through the collection of alpinas and hardy Ferns kept in pots for the purpose of filling up vacancies in rock garden. Rare or choice things are divided now for stock. Duplicates of the best things are kept in pots, and are plunged in ashes where shelter can be given in winter if required. Planted more Runner Beans. Shifted on young Vines in pots.

May 8th.—Moved bedding plants from a range of pits to temporary shelters, as pits are wanted for Cucumbers and Melons. A small amount of warmth will suffice now. Planted Brussels Sprouts for first crop. Hoe is often used now among young crops in kitchen garden. Top-dressed Cucumbers in hearing in warm house. Tomatoes swelling the fruit in early house have been top-dressed, and received liquid-manure.

May 9th.—Planted Veitch's Autumn Giant Cauliflower, a part being planted on north border. Sowed Thrushes, Lettuces, and French Breakfast Radishes. Early Potatoes on warm borders have been hooped over with Hazel rods and are covered with canvas at night. Put in more cuttings of Sage and Thyme, and made new beds of Mint. Our early beds are on a south border and late beds on the north.

May 10th.—Dusted snot over the spring-sown Onions. Vines are looked over every week to remove sub-laterals. There is a good deal of

Grape thinning to do now, which is done as far as possible in the early morning or in the evening. Pinched the young shoots of Plums in pots under glass to four or five leaves. Pears are not pinched so close, but the shoots are thinned freely. The fruit on the early trees has been thinned considerably. This leaves little more to do later.

POULTRY.

REARING TURKEYS.

(REPLY TO "LANSHIRE.")

TURKEY chicks require care in rearing, cold and damp being fatal to them. The coop, mother and chicks should be perfectly weather-proof. The position of the coop must be determined according to the state of the weather. In a dry season it may be placed upon short grass, but should the weather be damp an open shed will be found the most suitable. The chicks should have hard-boiled egg for the first week, but as they are rather slow in learning to feed themselves it is a good plan to set two or three hens' eggs when the Turkey has been sitting a week; the chicks will hatch out at the same time as the Turkey and teach the latter to feed without any trouble. With the egg-food should be mixed some Dandelion-leaves cut fine or green Chopped tops. During the first week feeding should take place every three hours. Stale bread-crumbs and Barley-meal may be given at the end of the first week or so. Curds separated dry may also be given, and the egg-food gradually dispensed with during the next three weeks. Later hard grain may be supplied in the shape of Buckwheat or Wheat. In the earlier stages the chicks may have Hemp-seed in small quantities. The Turkey-hen must be confined to her coop for a month at least, after which she may be let out for an hour or two daily. The coop should be frequently removed to fresh ground, taking care that the Grass in the immediate neighbourhood is kept quite short, for if the chicks be allowed to wander on long Grass laden with dew or rain much mischief will result. At eight to ten weeks old the young cease to be chicks, and are known as Turkey-poults; at this time the distinctive characteristics of the male and female are fully established. This is the most critical period of their lives, and their food, therefore, should be increased in quantity and made more nourishing. After this period they become quite hardy and able to take care of themselves, although it is advisable to keep them from rain and cold, so as not to try their hardiness too suddenly. A liberal allowance of vegetable food should now be given, as Nettles, Cabbage, Onions. These should be boiled and mixed with Barley meal or Oatmeal. With this diet may be given Oats, Wheat, Barley, and Sunflower-seed. The process of fattening should commence when they are six months old, as they take a longer time to become fit for table than fowls. The secret of obtaining good birds is to feed abundantly from their birth.—S. S. G.

BIRDS.

Green Linnet (*Adam*).—By "Green Linnet" you probably refer to the Greenfinch (*Loxia chloris*), a bird especially plentiful in our island, doing a good deal of harm in gardens during the spring and summer in destroying buds, and picking up sown seeds. If your bush has been brought up by hand from the nest it would probably starve if now released. If, however, it is a trapped bird it would be incapable of taking care of itself if set at liberty.—S. S. G.

Canary dying (*J. Taylor*).—This was a case of heart disease. In the region of the organ was found a large clot of blood; the rupture would, of course, result in instant death. Sudden death frequently happens to covek Canaries at the breeding season. You have probably been feeding the bird too liberally, or keeping it in too high a temperature. Seed mixtures containing Inga are dangerous to supply to cage-birds, and should be carefully avoided. The staple food for Canaries should be Canary-seed, but to counteract its fattening properties other seeds should be added, such as Rape, the best of

FRUIT.

BLIGHTED PLUM-TREES.

THE prevalence of cold winds and frosty nights as brought about an attack of aphides on plum-trees, which is a customary outcome of such weather. It is not a good plan to allow these intruders to go unmolested, for, with the amazing increase in their numbers from day to day, they soon inflict serious mischief on the tree unless quickly dealt with. The Abol insecticide, so often advertised in GARDENING ILLUSTRATED, is calculated to quickly destroy aphids on fruit-trees and plants, and so will compound Quassia extract or Tobacco-water. The latter, however, though effective, is most offensive and disagreeable in its smell and deposit on the leaves and fruit, and for that reason has gone very much out of use. Both Quassia and Abol insecticides are cheap, economical, easily mixed with cold soft water, and effective in destroying insect life. The Abol syringe is an implement that every fruit-grower should possess, because it not only does effective work by the fineness of its jet, but a small quantity of liquid is made to go far for the same reason. With ordinary syringes treble the quantity of insecticide is used than is necessary for the purpose, and as the Abol syringe is inexpensive it comes within reach of amateurs as well as gardeners. Anyone possessed of one of these little syringes will not readily give it up. An alternative, in the event of there being no insecticide at hand, is to go over the trees and pick off the curled leaves which envelop the insects. If this is done at the earliest period of attack, it would greatly assist in keeping down their numbers. This, however, is only recommended as a temporary remedy pending the application of an insecticide. It is a good idea to keep a little store of some kind of insecticide, so that when the necessity arises it is used there is no delay. When trees are attacked by aphids and they have to wait for medicinal measures to be applied, they become hopelessly crippled that there is both a loss of vigour and often a crop too before it can be harvested. Trees of any kind that are allowed to be over-ridden with insects, even if they are later, will fail to bear a crop. Thus it is seen how important it is to at once deal with insects in a practical manner.

W. S.

BURNING OF VINE FOLIAGE.

TO discuss in its proper sense, the burning, or rather scalding, of the foliage of Vines is the outcome of mismanagement, although in some instances this statement may be modified, as the structural arrangement of the vinerias is favourable for much of the injury which follows. The careful cultivator, however, when such injury can be traced to this cause, takes good care that anything which may be done to prevent it is attended to. When many of the main leaves are injured by burning, the fruit is deprived of much of its support; hence the grapes do not colour properly. When the

roof is glazed with common glass, let the structure be ventilated ever so carefully, burning is sure to follow. I refer particularly to those instances where the glass is full more or less of air bubbles. In these cases the surest cure, except, of course, reglazing the structure with better quality glass, is to colour over each bubble with some white lead thinned down with a little turpentine. The presence of air bubbles is soon perceived. If they are situated so that the sun's rays, if powerful enough at that time, strike the foliage obliquely, a "streak of burning" is seen for 2 feet or 3 feet. If one is situated so that it strikes directly on to a lateral, that portion will collapse, and it is the same with a solitary leaf if in a line with the bubble.

Other causes of burning are caused through the ventilation not being attended to properly. With this as the reason, it generally occurs after the berries are thinned and during the exhausting process of stoning. All this time there is a great strain upon the Vines, especially upon the fruit-bearing laterals, as if any burning does occur it is generally the fruit-bearing laterals which receive the injury, and which can ill afford to lose one leaf, let alone the majority. A variety that appears to suffer from this cause is the Muscat of Alexandria—that is, if the ventilation is not carefully attended to or if the glass is common. In this variety also a thin moisture settles upon the foliage at night, and if this should not be dissipated early on bright and sunny mornings by ventilation carefully applied, or before the sun raises the temperature, scalding or burning will result. For Muscats I find a slight shade applied during the hottest months of the year is highly beneficial. Not a thick shade, but merely a little whitening syringed over the roof. In all vinerias early and careful ventilation is what is needed, this being put on by degrees. Allowing the temperature to rise suddenly without any or little ventilation being on and then putting on a great amount will surely result in burnt foliage through the rapid evaporation of moisture.

WATERING FRUIT TREES IN BLOOM.

THERE is a wide-spread belief that it is a dangerous proceeding to water fruit trees when in bloom, and in the case of trees forced under glass the orthodox practice is to give the borders a good supply when the buds are swelling, and during the time when the trees are in bloom both borders and atmosphere are kept dry. We know that good crops are gathered year after year by people who do soak their fruit tree borders thoroughly so as to reach the roots, and then apply a mulching to prevent undue evaporation. But we are daily reminded that failures do also occur in the setting of crops under glass when it cannot be urged that spring frosts are the cause, for it is a very rare occurrence for spring frosts to be of sufficient severity to hurt blossoms under a glass roof. After careful observation I am convinced that dryness at the root is one of the most frequent causes of fruit trees failing to set their blossoms; in fact the blossoms drop simply from the inability of the tree to carry them further

than it has done. It cannot be always spring frosts that make the blossoms drop, even in the case of trees fully exposed. I am, therefore, strongly impressed with the belief that it is at the blossoming period that fruit trees require stimulants at the root in the shape of liquid food quite as much as when swelling their crops. During the present season I have been testing this subject in various ways, as our fruit trees both under glass and in the open air are more heavily laden with bloom than I ever remember to have seen them. Under glass I have not only given Peaches, Vines, Strawberries, and other fruits copious supplies of water at the root when in bloom, but I have on fine sunny mornings given a good syringing to the blossoms themselves, and I never remember having had so regular a set of fruit as I now have. Out-of-doors we cannot get enough liquid for all the trees that require it, and the amount of bloom is evidently a severe strain on the trees. This abundance of bloom is general in this locality. A successful grower of Peaches on open walls writing to me a few days back says, I have just had all our outdoor Peaches thoroughly soaked with liquid manure for the second time this season, as I always give them plenty when in bloom, and I would strongly urge on those who have fruit trees of any kind taxed to their utmost capacity with bloom, as they are this year, to lose no time in applying stimulants in a liquid form to the roots. The watering-pot works miracles if vigorously applied.

NOTES ON VINE CULTURE.

GARDENERS are very busy at this time of the year in the vinerias, and it depends much upon the treatment the Vines receive as to whether they will produce handsome bunches and large berries with good bloom upon them. All these houses require attention, and as I write these lines there is a keen east wind blowing, but at mid-day the sun has power enough to raise the temperature to a high point. Air of course has to be admitted, but it ought only to come in from the opening at the top of the house; it is better that the side-lights should remain closed. In one of our houses the Grapes are being thinned, and at such a time the berries may become rusty—as gardeners term the discoloration and contraction of the skin. "How is it caused?" I believe by careless handling of the berries, touching them with the hair of the head when thinning, or opening the front and top ventilators at the same time. This is sometimes done to make it pleasant for the person thinning during hot sunshine, but the cold east wind at such a time will do its work of injury. Thinning should, if possible, be done in the cool hours of the morning, and the smallest opening at the top of the house will admit sufficient air to make the atmosphere and temperature agreeable. In the second house the shoots ought now to be tied out, and stopping the growths should be frequently followed up. This is an important part of the culture of the Vine in the early stages of its growth. When growths are not wanted they should be stopped when they are about three inches in length. After stopping

from a good-sized vinery may be compressed into two or three handfuls if the work is done in good time. Some growers allow the laterals to run into shoots a yard or more in length before they are cut off. This cannot fail to be injurious to the Vines, by checking to a serious extent their growth. Stopping should be persistently followed up until the Vines have

The Wild Cherry or Gean (*Prunus Avium*).

reached the flowering stage, when it is best not to interfere with them until the setting period is over. It does not matter much as to the treatment of the Black Hamburgh or other free-setting varieties, but the Muscats and other shy-setting kinds may receive some sort of check which might have an injurious effect upon the setting of the blossoms. At setting time I raise the temperature about 5 degs. and keep up a rather dry atmosphere—not excessively dry, for the paths and borders are sprinkled daily. Thinning the fruit should be commenced about ten or twelve days after it has set. Muscats require a little artificial aid in setting, but if the weather is fine it is sufficient to shake the rods daily. It can be done by striking the wires with a hoe or a rod of some kind. W.

NOTES AND REPLIES.

The Strawberry prospect.—The present is an anxious time for the Strawberry grower. During the past winter there have been some severe spells of cold weather, which seemed to deal harshly with the outdoor beds, but the present prospects are very promising, judging from the freedom of their spring growth and the vigorous flower-trusses nestling in the crowns. I have recently given a moderate soaking of undiluted liquid-manure to the beds. Poured on between the rows of plants, this gravitates to the roots, enriching the soil to the depth occupied by them. I have for many years practised this with evident advantage. It is particularly on light soils where the value of this manure irrigation is apparent, but, of course, any land is the better for being well stored with stimulating food. Liquid-manure may be derived from the farm tanks, stables, piggeries, or from tanks provided for the reception of house sewage. Unless these means exist, there is no advantage in making liquid-manure artificially. Young plants at the present time show the greatest promise of future fruit, and which, it must be said, are always the most profitable, because their fruits ripen early and are finer than in the case of old plants. Strawberry plants that have been forced in pots, if well cared for afterwards, until they can be planted in the garden, will fruit well the following year. Such plants give

a heavy crop of medium-sized berries. Some gardeners deal thus with their forced stock of Strawberries, while others prefer to throw them away and depend on the open-air beds for their stock. With abundance of strong runners in July and August for planting after Potatoes or other summer crops, there is to me a gain of time and space by discarding the forced stock and devoting time and attention to the autumn runners. In small gardens, perhaps, planting a portion of the forced stock would be an advantage, because of the larger yield given subsequently. W. S.

The outdoor Peach prospect. From my own observations there seems every indication of a full and bounteous crop of Peaches from the open-air walls. The trees are healthy, and, though the weather has been so harsh, yet the trees are free from insect attacks and leaf-curl is quite absent. It is yet too soon to congratulate oneself on the absence of these spring troubles, but what is so remarkable is that, with weather so inviting to such tendencies, the trees should make such steady headway. Not only are the leaves and shoots progressing well, but fruits are swelling up with remarkable evenness, and with a return to more genial warmth there should be no need for anxiety as to the extent and fineness of the prospective crops. I have known in some seasons leaf-curl so rampant that every leaf would be removed twice and sometimes three times at periodic intervals. Up to the time of writing not a leaf has been removed from this cause, and it is to be hoped that with the advance of spring they will not give this trouble now. Both frost and cold winds were prevalent during the time of flowering. Past experience proves that the Peach flower is not so tender a nature as was at one time considered by many, and this year's results prove once again the truth of this. The above remarks apply to trees having a coping of glass and others without this protection.—W. S.

TREES AND SHRUBS.

SOME FLOWERING CHERRIES.

Of all the *Prunus* tribe, comprising as it does the Almonds, Peaches, Apricot, Cherries, and Plums, the Cherries when in flower are the most beautiful. The delicate beauty and grace of the blossoms reach in the Cherries their highest development. Neither are they surpassed elsewhere in the abundance of the blossoms, as may well be judged by the illustrations here given. A selection of the best of them is indispensable. Many of the best of the Cherries come from Japan and China, where long periods of cultivation have largely developed the size and attractiveness of the flowers. The same has happened at home with our native flowering Cherries, the double varieties of which almost rival the best Japanese varieties. The doubling of the flowers of Cherries is, indeed, in every way an improvement, adding to their showiness and duration without detracting in the least from their gracefulness.

PRUNUS PSEUDO-CERASUS, a native of China and Japan, is perhaps the loveliest of all flowering trees. In the best varieties of *P. pseudo-cerasus* the flowers are fully 2 inches across and of a soft rosy-white. One of the best is known as *Cerasus Watereri*.

PRUNUS AVIUM, the Gean or single-flowered Cherry, is a native of Britain, and is one of the parents of our fruiting Cherries. It makes an erect tree, 20 feet to 30 feet high, and flowers about the middle of April, when its branches become wreathed with clusters of mostly pendulous blossoms. The double-flowered variety of it is only second in value to *P. pseudo-cerasus*: it flowers with all the freedom of the type, whilst the doubling of the petals gives greater substance and durability to the blossoms.

PRUNUS PADUS, or the Bird Cherry, is another of our native trees. It is larger than

the preceding ones, reaching a height of 40 feet, and it flowers a month later. It varies considerably in merit, as might be expected from its wide distribution, for it extends from Northern and Central Europe to Manchuria and Japan. Some of its best forms have both racemes and individual flowers much larger than in others. We remember once seeing a fine variety which had racemes at least 8 inches long. One still finer is called *florapleno* and has racemes 8 inches to 9 inches long, each flower three-quarters of an inch across, double, and lasting longer in beauty than any of the single varieties. Another variety in the collection at Kew has large flowers and racemes, but is more especially noteworthy as coming into bloom at least a month earlier than our British Bird Cherry.

We hope the illustrations will lead many readers to represent the Cherries in their gardens more plentifully than they have hitherto done.

AZALEA MOLLISS.

THERE is a wealth of beauty and character in the race of *A. mollis*, and the idea that they are in any way tender is being gradually exploded. A group in the foreground of dark-leaved shrubs makes a splendid picture of various colours, and a good selection of the varieties of *A. mollis* comprises a great range of shades, from straw colour to intense scarlet, peculiarly brilliant when lit up by the sunshine of a spring day. In planting these groups in the garden the chief thing is to give them shelter from early frosts, which are apt to injure the buds and expanded flowers, but except for this precaution little need be said concerning their treatment. Many species abound in all good gardens where the hard Azaleas (*A. mollis* in particular) may be placed in shady quiet corners, away from winds and the influence of early frosts, just the position that agree with this delightful class of early spring-flowering shrubs. The soil that suits them best is peat, but fibrous loam will produce good plants. Hybrids have been obtained by crossing *A. mollis* with *A. pontica* and the Ghent varieties, and many beautiful things have resulted. A large group of *A. mollis* in full bloom is almost dazzling to look at through the rich variety of brilliant colours displayed in a good selection. The race is gradually improving. The flowers are not only very

The Bird Cherry (*Prunus Padus*).

charming for their extensive variety in coloring, but individually they are of large size, full rounded form, each segment broad, colored and firm.

VALUE IN POTS.—One great use, however, of the plants of the *A. mollis* type is their value for flowering in pots under glass. In a variety named *Anthony Koster* the flowers are especially

fully 2 inches across, well shaped, and brilliantly coloured deep orange-yellow, in which one could detect a suspicion of rose. Every twig is smothered with bloom, and in regard to the hazy Azaleas a great feature of the shrubs is their freedom of flowering, both clusters of bloom unrelieved by leafage. There are few, if any, shrubs of greater value for early blooming under glass than *A. mollis*, and either small or older specimens are a mass of flowers. When under glass all risk of injury from late frosts is removed, and the finest groups may be formed in the greenhouse or conservatory with them, mixed with a judicious selection of other subjects. Hard forcing is injurious. The plants require to be brought on gently in heat, and then the flowers last a considerable time both on the plants and when cut for vases. A few sprigs of the quieter coloured flowers mixed with Ferns or other suitable foliage are charming. In many gardens much waste occurs through the Azaleas, after they have been forced, being indifferently treated afterwards; but if they are required again for the same object, they should be well attended to. After blooming in a warm house, it is not policy to remove them at once to the open, where they are exposed to the vicissitudes of the early spring season. When the flowers are over, prune back the shoots and remove the plants to a cold-frame. It is unnecessary to coddle them, so give as much air as possible when the weather is not too cold. When they have got hardened and frosts are over, plant them out in a well-prepared bed in a moderately shady position, the soil a good fibrous loam, or, better still, peat, and in dry weather give water. During the summer they will make moderate headway, not much, perhaps, but the year after they will be in full health and strength. Even those who have only a conservatory or greenhouse may grow *A. mollis* to perfection if the plants are potted some time in the autumn, and the many varieties can be strongly recommended for this purpose.

Although there are many named kinds distinguished by their well-shaped flowers, a good selection of unnamed seedlings will give a great variety of the most refined and showy flowers. F.

NOTES AND REPLIES.

Cutting down Buddleia.—I have a *Buddleia globosa* which is very tall and ugly, as the branches for quite 2 feet are bare. Can I cut it down after it has blossomed?—W. I. L.

I moved a *Buddleia globosa*. The end buds still green. Ought it to be cut down?—(Miss) E. Jones.

May cut down your plant of *Buddleia globosa* when it has done flowering, in order that it may to a great extent recover therefrom before winter. With regard to the second plant, it may be treated in the same way.

Lonicera Standiehl.—As one of the earliest of shrubs to flower and also one of the most fragrant, this Honeysuckle has been a fairly well-known plant almost since its introduction from China in 1845 by Robert Fortune. Its flowers are not so beautiful as those of most of the Honeysuckles are, being comparatively small and of a creamy white. But in the spring every flower, however modest its attractions may be, is welcome, especially when it has so charming a perfume as this. The species is quite hardy and its blossoms stand rough weather well.

Shrubs for border.—I have a border, very open and exposed, which I wish to plant with shrubs to burn a screen. Will you kindly give me a list of suitable hardy, low-growing, evergreen flowering shrubs, with their height and time of flowering? When should they be planted?—P. P. H.

[Without any indications as to locality or soil, the difficulty of advising is increased tenfold. Still, low-growing, evergreen flowering shrubs are not very numerous, and, as they are to form a screen, it appears to us that anything less than a yard high would be inadmissible. Of evergreen flowering shrubs that will grow in ordinary garden soil may be named:—*Berberis Aquifolium*, 3 feet to 4 feet, yellow, March and April; *Berberis Darwini*, 5 feet to 6 feet, orange, April and May; *Berberis stenophylla*, 6 feet to 8 feet, yellow, April and May; *Choisya ternata*, 4 feet to 5 feet, white, May and June; *Escallonia uncinatum*, 6 feet and, summer; *Escallonia Phillyriana*, 6 feet, white, summer; *Ligustrum lucidum*, 7 feet to 8 feet,

white, August; *Oleum Haasti*, 3 feet to 4 feet, white, August; *Veronica Traversi*, 3 feet, whitish, summer; *Viburnum Tinus*, 4 feet to 6 feet, white, winter. Good evergreen screen plants, in which, however, the plants survive at all heights, are *Antennas* of sorts, Laurels, *Elaeagnus* of sorts, *Ononimus japonicus* and varieties, *Hollies*, *Osmantus* of sorts, and *Phillyrea Villmoriniana*. Where soil and conditions are favourable to *Rhododendrons* and their relatives, you have a wider choice, as *Rhododendrons* not only make a good screen, but flower beautifully, a remark that also applies to some of their allies, such as *Andromeda floribunda*, *Andromeda japonica*, and *Kalmia latifolia*.]

Jaeminum nudiflorum.—It is a wall plant that this winter-flowering Jessamine is most frequently grown. It is very beautiful in any position, but still a wall of brick or stone is not exactly the background to bring out its greatest attractiveness. It might be tried more often in the open ground in association with some dwarf evergreen. It does not flower quite so freely there as it does on a sunny wall,

The double-flowering Cherry (*Prunus Pseudo-Cerasus*). (See page 152.)

but still freely enough to be very charming. As a suitable evergreen to plant with it, the evergreen Barberry (*Berberis Aquifolium*) might be planted. Planted in the same group the dark green foliage of the Barberry is especially well adapted to enhance the brightness of the clear yellow flowers of the Jessamine. Owing to the rambling habit of the Barberry, it may need an occasional stubbing back or replanting to keep it from unduly robbing the Jessamine.

Lonicera fragrantissima.—Whilst *L. Standiehl* is deciduous, this is partly evergreen. In our hardest winters it loses most of its leaves, but in mild ones comparatively few. It is also earlier in commencing to grow. This adds a good deal to its value, for its white flowers show to much better advantage with their setting of leaves than do the naked ones of *L. Standiehl*. Yet the latter species is frequently sold for *fragrantissima*, although it is not on the whole so good a plant, *L. fragrantissima* being equally hardy and equally fragrant. It may be distinguished by the following characters: It is partly evergreen,

flowers rather later, its leaves are unpari-tively round and broad, and much less pubescent than in *L. Standiehl*. Both are certainly well worth growing, but, of the two, *L. fragrantissima* is to be preferred.

The golden flowering Currant (*Ribes aureum*).—Although this shrub has a rival now in bloom (also with yellow flowers) in the shape of *Forsythia suspensa*, whose attractions, this season especially, are so brilliant as to put it somewhat in the shade when both are seen at a distance, it is, I think, at close quarters a shrub of almost equal charm. Its neat foliage is at this early stage of a singularly pleasing tender shade of green, and intermingles most effectively with the short crowded flower-spikes. The flowers vary a good deal in size and colour. In the better varieties the flower individually is close on half an inch in diameter. The colour is always yellow, but ranges from a rather pale shade to golden or orange. The variety *aurantinum* is perhaps the best, having not only richly coloured large flowers, but it is also of a sturdier habit than is common to the species as a whole. The flower-spikes are slightly drooping and 2 inches to 3 inches long. The shrub does not often attain a greater height than 6 feet or 8 feet. Like the other flowering Currants, it can be easily and rapidly increased by cuttings. It was introduced from North-western America in 1812.

The double-blossomed Cherry Plum and Prunus Pissardi.

Very beautiful objects are these two lovely shrubs when well flowered. We have them growing close together in long rows. The plants are in their third year, and are in upright cordon form, all their side growths having been spurred in with a view to forming them eventually into standards. Anyone may make a very interesting dividing line with these two trees, which in early spring at least will be objects of much beauty, and even later on the *Prunus Pissardi* will add a beautiful tint of colour to the garden. I would suggest the planting alternately of maiden or one-year-old plants. Give them the support of a cane the first season, and pinch in the lateral growths in the same way as one would a cordon fruit-tree. In course of time these plants will be a mass of blossom from the base to the top, and with age will become dense with flowering spurs, so that each year such trees naturally increase in beauty.—ROSA.

Cydonia japonica—severe pruning a mistake.

—This, like many other shrubs, suffers considerably from a too severe use of the knife, and often the grower complains of its non-flowering, when the remedy is in the hands of the owner. Generally, it is planted against a wall, verandah, or something of this kind—frequently in a position quite unsuitable—consequently to keep it tidy-looking every bit of young wood is kept cut in close, causing it to grow coarse. The best-bowered bushes are most frequently in farm-house and cottage gardens, where the knife is not understood, or, at any rate, not used to any extent. I pass a large plant frequently. It is grown upon a farm-house at the foot of an east wall. The only attention it gets is keeping it to the wall, the very long fore-right shoots being cut in during summer, and this spring for many weeks it has been a mass of bloom. I have a very old plant, and for years it was pruned severely, with the result that there were only a few flowers. Of late I have let it have its head, and now it is satisfactory. Some years ago I saw a grand plant of the white form at Clarendon, Surrey, against one of the old walls, covering many feet. It was in bloom at the time of my visit, and I could not help noticing how little wood it made, and the abundance of bloom. Some think the Ceylon cannot be grown away from a wall, but this is not so. I have seen fine bushes in pleasure grounds. This should have a place in every garden, as it grows rapidly and costs very little to buy.

PLANTS AND FLOWERS.

CHRYSANTHEMUMS.

SEASONABLE NOTES.

This time is drawing near when the majority of amateurs and others will be giving their plants their final shift into 7, 8, 9, or 10-inch pots, as the case may be. Eight-inch pots I find the most convenient for all purposes, although, if it is preferred, three plants can be grown on in the 10-inch size; but the latter are somewhat clumsy to move about, and are not to be recommended to small growers. What I prefer for the final shift in the way of soil is good turfy loam, broken up in pieces about the size of a Nut, into which have been sprinkled a good dash of bone meal and about half a port sharp river-sand. This should be thoroughly mixed, and should neither be too wet nor too dry. Another important item is the drainage—one large crock over the hole in the pot and a number of smaller pieces above that, and on that again a handful of $\frac{3}{4}$ -inch bones. With the continual watering of the plant the bones become dissolved and form valuable material for the roots to feed upon. Care should be taken to make the soil very firm in potting, as such is essential to short, thick-jointed growth, and to an abundant harvest of flowers later on. A stick should be used for ramming the soil firmly, and nothing is better than the top part of an old spade handle, 16 inches long and sawn square across, just on the same principle as the dibbler, only in this case instead of a point being made it is left flat.

Sufficient room should also be left for water by leaving the soil not less than 1 inch from the top of the pot. Watering is another item that requires great care and judgment, and when done it should be thorough. If sufficient is not given, the roots at the surface take it all, while the roots at the bottom are dry and parched, and, if such a state of matters is allowed for any length of time, failure and disappointment are sure to follow. As soon as potted the plants should be staked, preferably one stake to each shoot, but all the branches may be looped together to one strong stake in the centre. D. G. McIVER.

Bridge of Weir, N.B.

RAISING SEEDLINGS.

THE raising of seedling Chrysanthemums is very much of a lottery. Still, when one single sterling novelty can be had from seed, it affords encouragement for still further trial. Of course, if seed is sown, a very large percentage of worthless varieties must be expected. Much might be done to encourage the raising of Chrysanthemums by offering prizes for home-raised seedlings. The conditions as to time should be unlimited, though it is not possible to treat seedlings like ordinary annuals. Two years really are required before the plants can be tested properly. There is a tendency amongst seedlings to show large eyes the first season, these in many instances being condemned as worthless. If a second year's trial of these were carried out, a greater percentage of desirable blooms would, no doubt, be obtained. Generally raisers of seedlings are so anxious to see the results, that the plants are run up with one single stem and allowed to bloom. Even well-known good kinds exhibit a marked difference both in colour and formation when allowed to develop blooms from the side shoots also. So much does this affect some varieties as to make them hardly recognisable; therefore, in the case of undeveloped seedlings we may expect similar results. The growing of seedlings occupies much space and time. A good plan is to plant them out-of-doors in some sunny, open situation and allow all that will to flower in the open, even if protection from early frost in a temporary manner is necessary. An idea can be formed of those likely to be worth a further trial, and much valuable space will be saved. Where, of course, space under glass exists for blooming the plants even the first year, I recommend strongly that there they be flowered. Pots 7 inches in diameter are large enough for the first year's growth. No check should occur to the plants in the way of allowing them to

become root-bound in their initiatory stages. The one desirable point about seedling Chrysanthemums is that the height of growth and general habit can be controlled by carefully selecting suitable types of growth as the seed-bearing parents. Not so with sports. In all instances the habit of growth partakes of that from which the sport originated, no matter whether it is desirable or not. No form or method of culture can alter this.

SOIL FOR CHRYSANTHEMUMS.

A MISTAKE is often made in making this too rich with animal and concentrated manures. Three-fourths of the compost may be loam. This differs considerably in quality, and is more or less difficult to obtain. The top spit of meadow land is what one covets, and if clayey rather than sandy, so much the better for the purpose. It should also be of a fibrous nature. If this be obtained a few months before use, one is not troubled so much by the Grass growing on the surface after potting. Chop it in pieces, but not too fine, and add the other portions. The other fourth part may consist of leaf-mould and decayed manure. Rubble, such as old mortar and brick rubbish, is used when the loam is of a very close nature. Bones in a fine state, at the rate of 1 lb. to the bushel, will greatly assist in building up a sturdy growth and give a healthy tone to the foliage. Mix all well together some time before the soil is to be used, and get it in an even state of moisture, neither wet nor dry. Pots of 10-inch diameter are now commonly used by the best exhibitors, except for the more weakly-growing kinds; in the case of these a size smaller is employed. For other than the growth of large blooms or gigantic specimen plants, the 9-inch, or even a size smaller, is large enough, and generally more convenient for Chrysanthemum culture. It is not advisable to use much drainage, but the crocks should be placed evenly over the holes and bottom of the pot. Half-inch bones may form part of the drainage, and are highly beneficial to the roots that run so abundantly downwards. Be sure that good, well-cleansed bones are obtained. Instances have been known where this material has formed into a putrefied mass when made moist, and has killed every root that came into contact with it. Two hours before the plants are turned out for repotting give the earth a thorough soaking with water. This is very necessary, for not only will the ball of earth turn out intact and without damage to the roots, but if it be not done there is danger of the older soil becoming dry whilst the new is quite moist, a serious check in the growth of the plant thereby resulting. Firm potting is an essential point. After each plant is potted it may be readily staked (if this has not already been done), and the pots stood close together in a slightly shaded position for a few days. This checks evaporation, as we want to avoid watering the earth until the roots have taken to the new soil. It may be necessary to sprinkle the foliage in the morning and early evening. When the roots get on the move again the plants can be stood in their summer quarters.

Enemies of Chrysanthemums.—

Green and black aphides are troublesome at this season. They should be dealt with promptly. Dusting with Tobacco-powder is a convenient method of destroying such. Another pest that often attacks the plants during spring is the leaf-mining maggot. It makes marks between the tissues of the leaves and is thus readily found. Hand-picking is the best remedy. This, again, should be dealt with promptly, because it spreads rapidly and the foliage soon becomes disfigured.

Potting Chrysanthemums.—One of the most important items in culture is to keep the plants growing freely by transferring them to larger pots as they require more space for their roots, putting those plants for the production of large blooms into pots $\frac{3}{4}$ inches in diameter. For specimens an inch more is not too much at this stage, and those for bushes and late flowers should have 5-inch pots. Pompon, Anemone-pompon, and single varieties succeed in 7-inch and 8-inch pots for the final shift. In all cases employ a substantial compost, avoiding much manure, although sufficient for the production

of vigorous growth must be given. Pot firmly, as if the soil is placed around the roots in a loose way the growth made is not firm. It is useless to expect deep, solid blooms without ripened wood. It is also useless to attempt to ripen or mature it in a couple of months previous to the flowering of the plants. Maturation must proceed along with growth. All newly-potted plants should be kept a trifle closer in the frames for a few days until the roots are running into the new soil, when all the air possible should be given. Plants growing in frames or pits should be fully exposed to induce a stocky growth—in fact, the lights ought to be drawn off them altogether upon all favourable occasions. It is too early to expose them entirely by night without some protection. Plants crippled at the points by exposure receive such a check to growth that they seldom recover. Abundance of space should also be allowed between the plants.

GARDEN PESTS AND FRIENDS.

Angles shades moth.—Would you kindly tell me the name of enclosed caterpillars? My Anemone japonica were so infested with them that I had to dig up the plants, shake over newspaper, and plant in another part of the garden. Do they not turn into chrysalides in the water?—KENTWORTH.

[The caterpillars you sent are those of the Angles shades moth (*Phlogophora metuculosa*), a very common insect. The caterpillars of the second brood do not become chrysalides until about this time of year.—G. S. S.]

Fungus in viney border.—Herewith I forward a specimen of what appears to be a fungus, which I have taken from the soil of my viney. I shall be obliged if you can tell me what it is, its probable origin (only observed this spring), and method for its eradication!—Gazansau.

[The white substance from the soil of your viney is, as you thought, a fungus, but it is only the mycelium, or spawn, so that I cannot tell to what species it belongs. It probably began by growing on a piece of decaying wood, and possibly will not injure the Vines, but as I cannot be sure on this point it would be better to remove all you can find and burn it.—G. S. S.]

The Swallow-tailed moth.—I received a matchbox containing a caterpillar, but there was no note or paper of any description to say from whom it had been received. The envelope was much torn, and the accompanying letter had probably fallen out. The box and envelope were enclosed in an official envelope marked that it was received in this state. The box contained a caterpillar of the Swallow-tailed moth (*Ourapteryx sambucaria*), one of the Geometridae. The caterpillars of this family can easily be distinguished from those of other families by their legs, which are placed at either extremity of their bodies, with none on the middle joints. This arrangement causes them to walk in a very peculiar manner. Holding on tightly by the feet at the end of its body, the caterpillar stretches itself out to its full length. It then, with the feet near the head, takes a firm grasp, and, releasing the other feet, arches its back and draws the end of its body as far forward as possible, forming itself into a kind of loop, from which circumstance it is commonly known as "looper." Many of these caterpillars have the habit when at rest of holding tightly to a stem by the feet near the tail and stretching their bodies into the air at an angle, so that they exactly resemble a twig. In this position they will remain motionless for hours.—G. S. S.

Cottagers' flower shows.—I greatly regret to learn that in some rural parishes it has already been determined to shunt the usual annual flower show for the present year on account of the severe demand being made on local people—the chief supporters of these shows—to subscribe to the coronation celebrations. Did this celebration but occur in July rather than in June, it might have been possible perhaps in some districts to work in with it the ordinary flower show. June is far too early for garden produce to have attained maturity. The maintenance of these cottagers' exhibitions is a matter of great importance to rural horticulture. Still further, there is the possibility that once the show is dropped it may not again be revived. The raising of funds wherewith to pay expenses and prizes is dependent on the local residents, and few have exceptional incomes to meet exceptional demands.—G. S. S.]

ROSES.

ROSE MME. BERARD.

THIS Dijon Tea Rose, with its salmon-tint flowers, is one of the most effective for covering a large expanse of house wall, as may be seen from the accompanying illustration. Making rapid growth and often producing shoots 15 feet or more in length in its annual growth, it soon ascends to the eaves of the house and wreathes the open upper windows with the soft tints of its countless blossoms. Its chief fault is a tendency to mildew, but where this can be kept under it presents a charming summer picture. The old favourite Gloire de Dijon, which is perhaps the best Rose for a standard that we possess, old plants with huge

spider gains the mastery the plants will suffer. I think "E. J." would have assisted the readers of GARDENING more if he had stated his system of Rose culture under glass—whether he forces his plants or cultivates under cool treatment. I readily grant the syringe may be dispensed with under this latter method, but I would not care to try the experiment on my forced plants, or should expect to find them with no foliage to syringe after the red-spider had done its work. It is tolerably well known that "soft" foliage predisposes the plant to mildew attacks. But I maintain we can syringe our plants and yet have the foliage hard, and this by a judicious system of ventilation. Knowing right well that the fungus spores of mildew will not germinate on a dry surface, I have found it an

The following excellent recipe for a fungicide given to me by a first-rate gardener may prove useful to the readers of GARDENING if they are less fortunate than "E. J." and find their plants attacked: One peck of lime, 1 peck of soot, 6 lb. of sulphur, boiled together for two hours. When cool use $\frac{1}{2}$ pint to 4 gallons of water (preferably soft water). RNSA.

NOTES AND REPLIES.

Rose not starting.—In February I moved to another garden a climbing Rose, either La Mirlouane or Félicité-Perpetue; I lost the name. It had grown very high. There was severe weather after it was moved, and now it shows no signs of life. Shall I cut it down to the ground, or shall I leave it, as I wanted it to cover a bare wall?—RNSA.

[As the plant was so recently transplanted, it would not be starting into new growth just yet.

Supposing the wood is green and firm, there will be no need to prune it so severely as you suggest. We should, however, advise you to prune the plant back to within, say, 3 feet of the ground, then, later on, when the roots become active, new shoots will break out. You can materially assist the plant by syringing the wood every morning early, before the sun gains much power, and a little water at the root will be helpful. If the Rose is on its own roots, new shoots will doubtless appear after midsummer. These will quickly furnish the wall. When it is decided to transplant Roses that have been for some time in present location, the work is best done early in autumn. It is always very risky to defer it until spring.]

Rose failing.—Some days ago I transplanted a Rose, digging a hole about a foot deep, and filling in after manuring well and watering. But it began to wither immediately, and now is dying. Can you tell me the reason of this, and give me any short directions for transplanting Roses, as I shall have to try and fill up the place with another. Could you name a good book on Roses that gives directions as to pruning, etc., cheap?—(REV.) J. D. PIERCE.

[If the plant was a young one, not more than 2 years old, it certainly should not have behaved as you say this one has done, but if an old specimen, the lateness of the season would largely account for the withering. Then, again, you say you dug out a hole about a foot deep, and gave the plant a liberal amount of manure. In the first place, a foot deep was not sufficient depth to dig. A hole 2 feet deep and 2 feet wide should have been dug, adding a shovelful or so of well-decayed manure with the lower stratum of soil, returning the soil to the hole. You should after such digging have taken out a spadeful or two of the soil, disposed the roots regularly around, then returned the soil and made firm. Newly-planted Roses prefer being planted in soil that has been deeply dug, and they resent strong manure near their roots. It is safer to

give them liquid manure in the summer than to make the soil manuring to the plants by adding such a lot at time of planting. Your best plan now will be to plant a pot-grown Rose, as the season is so far advanced. Rush plants that were potted last autumn are preferable. They are usually grown in 8-inch pots. When planting such, turn out the plant carefully. The ball of earth must remain intact. Such plants make grand bushes by the autumn. A very useful and practical little book on Rose culture is Mr. Wm. Paul's "Roses and Rose Culture," price 1s., from the bookstalls.]

As many of the most interesting notes and articles in "GARDENING" from the very beginning have come from its readers, we offer each week a copy of the latest edition of either "STOCK AND GERRARD'S PLANTS," or "THE ENGLISH FLOWER GARDEN," to the reader of the most useful or interesting letter or short article published in the current week's issue, which will be marked thus: *

Rose Mme. Berard. From a photograph sent by Mr. J. Cobbett, Cemetery Road, Staughton, Guildford.

heads often being seen in cottage gardens in the best of health, is also well adapted for planting against a house, in which position it is probably more used than any other Rose. Rêve d'Or is another excellent Rose for the same purpose, bearing its yellow-tint flowers in prodigal profusion during the early summer, and soon clothing bare expanses with its handsome, shining leafage, which has the merit of being practically evergreen. This Rose does best when not subjected to hard pruning, which is apt to produce rampant growth at the expense of flowers. The growths of the current season should be laid in as they mature, only the oldest wood being cut out when the wall-space becomes unduly crowded. Bonquet d'Or, with deep yellow copper-centred flowers, is a fine Rose, bearing an immense crop of bloom, as does the well-known William Allen Richardson. This latter Rose is, however, not advisable for covering hot, sunny walls in the south, as in such a site the flowers show scarcely a trace of the rich apricot tint which they should possess, but assume a dull, parchment-like colour that has nothing to commend it. In cooler districts, on shadier walls, or when associated with other climbers in the south, the flowers usually exhibit their rightful exquisite colouring. On page 53, Vol. XXI., is an illustration of W. A. Richardson covering a house-front in South Devon in conjunction with Ivy. Although the exposure was a southern one, this Rose always produced flowers of a rich apricot tint, owing to the leaves of the accompanying Ivy preventing undue heat being thrown off by the wall. With reference to this association, one would scarcely recommend the planting of a climbing Rose and Ivy together, but, where the roots of the Rose can be kept clear from interference by those of the Ivy for two years or so and are liberally fed, the plant makes such a strong start that it will often successfully contest the roof-run with the most rampant of neighbours. Ideal is another climbing Rose most desirable on account of its unique colour, in which carmine, copper, orange, and saffron are often indescribably mingled. The pale flush Climbing Captain Christy is also a charming Rose which is far more rarely seen than its merits deserve. S. W. F.

MILDEW ON ROSES UNDER GLASS.

I do not suppose such an excellent cultivator as "E. J." would tolerate an attack of red-spider upon his Roses under glass, but his advice not to syringe the plants appears to me to be rather open to misconception by the novice. I would prefer to have mildew on my Roses rather than red-spider. There is plenty of remedies for the former, but when one has

excellent plan to leave a crack of air on the top ventilators at night, so that a nice hygienic atmosphere is maintained. I could take "E. J." to several houses of Roses planted out that are quite free from mildew, and which are hoed nearly every morning with cold water just as it comes from the main, and this in houses that are artificially heated. The grower has often remarked to me that he attributed the absence of mildew on his plants to this system of syringing, which tended to harden the foliage. Mildew arises more frequently through too much or too little water at the root, and also too strong solutions of manure. Those plants from which the water passes away very slowly are also much addicted to mildew attacks, and the lesson to be learnt from this is to aerate the soil by providing a porous peat compost, and to stand the plants upon two bricks or an inverted pot

OUTDOOR PLANTS.

* * LILIUM AURATUM AS A BORDER PLANT.

This is indeed a truly glorious Lily, whether we refer merely to *L. auratum* or its varieties *rubro-vittatum* or *Wittei*. In spite of the fact that the bulbs are annually sent to this country from Japan to the tune of tens of thousands, how very seldom do we see it thriving in our gardens! Unfortunately, of late years these bulbs leave much to be desired—firstly, owing to the removal of the bulb-feeding or basal roots by the Japanese before shipment; secondly, the deliberate neglect of precautionary measures with a view to combat the "Lily bulb" disease by fungicides; and, thirdly, the close packing in powdered clay, which dries up the bulbs, and thus again diminishes their vitality.

Perhaps a few suggestions on the outdoor cultivation of this Lily, gleaned from a few experiments, may be of some little help. My experience leads me to the view that success with *L. auratum* depends more on the selection and subsequent preparation of the bulbs for planting, and a compost easily prepared for their reception in the border, than the particular site, climate, or soil of the garden.

SELECTION OF THE BULBS.—Choose those which reach this country between the 1st of February and the end of March—late enough for proper maturing of their growth in Japan, and early enough to make a start with hopes of success—of medium size, but weighty, with regularly disposed scales, free from decay spots, and, above all, bulbs from which none of the scales have been removed. Unfortunately, the basal roots, which nourish the bulb, in contrast to the stem roots which nourish the flowers, will have been removed before shipment; but I endeavour to select those which, in spite of this amputation, have a goodly portion attached to the bulb, dead and dried up though they may be. Such bulbs emit new basal roots far more readily than those which practically show no trace of their old ones. So, heavy, firm, fair-sized bulbs, 4 inches to 5 inches in diameter, reaching us in February or March, with all the outer scales *in situ* and portions of old basal roots still adhering, would be my choice. It will be noted that such bulbs have the basal roots proceeding from a slight depression. If, instead, these roots proceed from a protuberance, however slight, some of the outer scales have been removed, bringing the root-stock forward. Such a bulb is almost surely badly diseased, and the scales have been removed to hide it. Adieu to the foregoing. I should never purchase bulbs that had been exposed any length of time, either to air or light. Directly they reach us and are removed from the clay-dust packing, they should, I believe, undergo the preparation for planting, for, given promising bulbs, our object must be to get them out of their dormant state—to quicken them, as it were, into growth, without at the same time awakening the germs of that terrible plague "Lily bulb disease." No doubt this scourge claims its victims in spite of every care, but a bulb planted recklessly in any unsuitable soil whilst at the lowest stage of its vitality probably never has a chance to quicken, the fungus making short work of it. A case of bulbs may be seemingly healthy at the beginning of a week and a mass of decay at the end. I immerse my bulbs on receipt for two minutes in a fungicide, subsequently draining them, basal roots uppermost. Permanganate of potash $\frac{1}{2}$ oz., mixed in 1 gallon of water, seems to accomplish the object, and is satisfactory; but any fungicide suitable to plant life would avail, say Bordeaux-mixture. When dry place the bulbs in a box, on a layer of quite damp Coconut-fibre, covering them with the same, and keeping quite moist. Stand the box in the temperature of a living-room. At the end of ten days examine them, and remove those which show traces of the disease to a box filled with fibre, first removing all diseased portions. At the end of three weeks the bulbs will appear very different; the scales are now plump and very brittle, and they fit quite tightly toward a common centre. In the most successful cases basal roots are issuing again, and in some cases these may be 1-2 inches long. Vitality is being restored.

speaking, all bulbs seem to show—on the scales, at any rate—doubtful patches, and if these show a disposition to spread toward the base, immediately destroy the bulb; but little local rotting spots upon the scales may be lint bruises. I have never seen a perfectly sound-looking bulb of *Lilium auratum*. Given a good dusting with flowers of sulphur, the bulbs are now fit to plant. With regard to suitable

SITES FOR PLANTING in the open border and irrespective of planting among Rhododendrons, where they nearly always succeed, select a sheltered warm border, choosing, if possible, for a clump (say of twelve) the shaded side in front of some tall-growing perennial—a *Rudbeckia* or a tall *Helianthus*, for example, the object being to have the Lilies enjoying the rays of the warm sun during the later spring, but as the season advances the stems of the tall-growing perennial afford shelter and shade. Drainage must be perfect. For a clump of a dozen dig a hole 2 feet in diameter and about 16 inches or 18 inches in depth, and unless the soil be of a peaty character or a staple known to be quite suitable to *Lilium auratum*, place a layer at bottom, to a depth of some 9 inches or 10 inches, consisting of equal parts good peat and loam. It is advisable to add above this a shallow layer of Coconut-fibre and sand, upon which the sulphur-coated bulbs are to be placed. A handful of this fibre can then be thrown upon the top of each Lily as a deterrent to worms, subsequently adding 3 inches or 4 inches of the ordinary garden soil. A layer of very rotten horse or cow-mannure above this will in good time feed the stem roots, and the whole can be made level with a surfacing of ordinary garden soil. Keep the layer of rotten dung not less than 4 inches from the top of the bulbs. Peat may be dispensed with, and good results obtained with Coconut-fibre, sand, and loam, and a little good, sweet leaf-mould. Prepared bulbs of *Lilium auratum* planted in this way yield stems sometimes thicker than one's thumb, pointing to the suitability of the treatment. The flowering period of twelve such bulbs will frequently extend from mid-July to mid-October and even later. Another disease may attack the buds, stem, and leaves, but occasional spraying with the fungicide mentioned, or the Bordeaux-mixture, keeps this in check.

At all times during great heat the ground should be copiously watered. In early winter, when the stems are quite dead, they should be cut down, and, given average luck, a display the following year, little inferior to the first, may be confidently expected. At the end of the third or fourth annual display the bulbs will, I fear, be no longer worthy of their site. Experience, however, tends to show that, until this deterioration of the bulbs is apparent in growth and bloom, they are best left undisturbed.

As a supplement to the Lily display, *Ranunculuses* may be planted in the top stratum of the soil above the cow-mannure—of course, in cases where the staple suits them—and seemingly the growth of these assists the Lilies below, but both should be planted by the end of February or the *Ranunculuses* may fail.

A. J. ORKMEYER.

Beechbrook, Hyde-road, Roxborough-root, Harrow.

PLANTING OUT TOO EARLY A MISTAKE.

WHEN we get into May many lovers of their gardens begin to think all the cold weather has passed. If we may judge by the questions put and experience given in *GARDENING ILLUSTRATED*, many are too hasty in placing tender things in the open ground before the weather is settled. During my gardening experience I have often been asked, when may I begin planting out? This question is far more easily asked than answered, seeing so much depends on where the grower resides, the position of the garden, the kind of plants grown, and how the plants have been treated as regards hardening off. In seaside places things may be placed in the open a month earlier than in cold districts, and if the garden is sheltered a fortnight before they can be in an exposed or low-lying position. Plants that have been grown hardy, and well exposed may be planted out many days before those grown otherwise. Much also

depends on the kind of plants grown. *Calcocaryas* of the Golden Gem type can be safely placed in the open a month before such things as *Coleuses*, etc. As many readers of *GARDENING ILLUSTRATED* obtain many of their plants from florists, it may be wise to give them a word of warning against obtaining large plants that have been grown in strong heat and moisture. These look very well when sent home, but note how miserable they appear if placed in the open beds and exposed to cold winds, sun, and frosty nights. Frequently these lose half of their leaves, and do not commence to grow for many weeks. It would be far better to purchase a plant not half the size that has been grown hardy and well exposed. Such plants do not suffer from climatic changes, and they grow away at once. In gardens where beds are devoted to one or two sorts of plants it is easy to arrange the filling of these; but where beds or borders are large, and a large variety of plants is used, then this is more difficult, seeing they are often ready to go out at an early date. No class of plants gives so much pleasure at so small a cost as annuals, and I am convinced many a garden could be made beautiful through the whole year by growing annuals and hardy plants. A very large number of the annuals grown for summer gardening do not give half the results they ought from being grown in hot structures and then planted out without any protection. Many people pride themselves when they have plants to go into the open of *Asters*, *Stocks*, *Phlox*, *Zinnias*, and a host of other things I could name that have large deep green leaves. I prefer plants that have leaves of much less size and with a brownish look. Many annuals would be far better if they never received anything hotter than a cold frame, and if not sown too early so much the better, as then they may be pricked out where they are to bloom and make a grand show by the close of the summer. For very late blooming I have had the best results from sowing under handlights in the open border and pricking out into the beds or borders during the last half of June. Many complaints are made as to *Zinnias*, *Salpiglossis*, etc., not growing away well when first planted out. This frequently arises from being sown too early. The last few days of April and early in May are the best times for sowing *Zinnias*, and last year some *Salpiglossis* self-sown in the borders were more satisfactory than those raised under glass. J. CROSS.

A hard-and-fast rule cannot be laid down as to the date one may safely put out bedding plants, so much depending on the season and the locality in which the grower resides. It is better to wait a week or ten days than to plant and have all one's plants destroyed by a single night's frost. One should, of course, commence to put out the hardiest things first—those that have been wintered in cold frames, such as *Pansies*, *Calcocaryas*, *Antirrhinums*, *Pentstemons*, etc.; then following with *Pelargoniums*, *Pyrethrum*, *Lobelias*, *Stocks*, *Asters*, *Phlox Drummondii*, *Perilla nankinensis*, leaving until the last *Zinnias*, *Echeverias*, and *Alternantheras*. There are those who dispense with the hardening-off process altogether, considering it unnecessary, removing the plants direct from the greenhouse to the beds and borders, but this can only be done at great risk, and when practised is often attended with damaging results, as severe frosts ensuing—a not unlikely thing in May—all one's work is liable to be undone. It is therefore, best to follow the safe and sure medium of the cold-frame for a fortnight, leaving the sashes off in the day, and replacing them partly at night, until they can be dispensed with altogether. I have seen plants of *Pelargoniums* *West Brighton* (Gem, Bijon, Sunset, and fine-foliated sorts taken from a warm greenhouse to beds, with the result of loss of colour, and a check given that has taken weeks to overcome. W. F. D.

Many of our suburban and country residents round about here are tempted by the good weather we are experiencing to put out their tender plants, and to such I would say "dwt," if you wish your flower-beds to figure prominently in the neighbourhood. It does not matter how well a plant may be hardened off; it gets a few degrees of frost while in its permanent position, it is crippled all through

the summer, and fails to give the satisfaction that one expects. In Scotland, the first week of June is considered a good time for bedding out, and even then I have had Dahlias spoiled owing to frost. It is well to wait a little, until the east winds, which blight our plants even more than a touch of frost, are over, at any rate.

Bridge of Weir, N. B.

D. G. McL.

THE ARUNDOS (REED).

By some the Arundos are regarded as inferior to the Glycerium or Pampas Grass, and, indeed, it may be so as ordinarily seen and grown, and by a comparison of both at the same moment. As a matter of fact, however, such a Reed as that shown in the accompanying illustration possesses a value but little, if any, inferior to the average Pampas. Both are of about equal hardiness in British gardens, and both require

of this plant as is afforded by the illustration. The long, silky-white, drooping racemes are very showy, and remain in excellent condition for two or three months together. The strong, established plants flower in the early summer, often early in July, and remain good until autumn. In this respect the plant is far in advance of the Pampas, that often sends up its plumes quite late in the year. Where lake or pond exists this handsome flowering Reed may be planted at the margin. Root interference should never be undertaken late in the autumn or in winter. In spring, with returning activity, the plants may be divided with impunity.

A. DONAX (The Great Reed).—In this the leaves are alternately disposed on stout, reed-like stems that attain a dozen feet or 15 feet high. In colour they are glaucous green and arching. The flowers are at first reddish, but ultimately nearly white, the numerous spikelets

altogether, as they have had very fine flowers on them, and now the leaves, which have been very small and stunted-looking, have turned yellow. Is it from disease, or do the plants only want a change of soil? They have been in their present position three years.—M. L. C.

[Again and again we endeavour to impress upon our correspondents the great necessity of sending ample material so packed that it may reach us quite fresh. By not conforming to this very simple yet essential request, those in search of information are the losers. The few leaves you send are quite inadequate, whereas a plant, or a portion of one, wrapped in damp Moss, and reaching our office as fresh as it left its starting point, may at once give us the clue to the wrong. If this be neither conveyed in words or by specimens, we are helpless to assist. The leaves were quite shrivelled, yet judging from the colour, and from the time the plants have been in the one position, it would appear the soil is exhausted. In some soils Violets will go on for years, running about rooting here and there and flowering well. Of the kind of soil "M. L. C." grows the Violet in we have no information. Broadly, however, we may say this, that only the best growth and finest blooms are to be obtained by treating these plants as annuals. In other words, take unflowered runners in October and treat as cuttings. In early April following plant these cuttings, which have reached the stage of nicely-rooted plants, in good, rich soil that has been deeply dug and manured in the winter. Hoe and water as may be necessary in summer, and by September tufts will be formed that will teem with buds and produce flowers all the winter long. All you can do now with yours is to plant some in fresh ground to produce the necessary cuttings in autumn.]

Seedling double Violet (J. T. B., Wollaston).—The exceeding brevity of your note falls short of one essential detail in that it does not clearly convey if you desire to know how to raise stock, or whether you wish to bring it into prominence by exhibiting it. Of the actual merit of the blossoms we cannot speak. Such flowers should always be wrapped round in damp Moss, and even stood in water for an hour before packing to assist in reaching us in a quite fresh state. After about fifteen hours in water one or two of the blooms picked up, and if these are representative, the flowers are white heavily tipped with purplish violet—suggesting a mixture of Comte de Brazza and Marie Louise, or something near. One thing we can say—the flowers are very strongly and deliciously perfumed. Had you sent a small plant with the roots in wet Moss we could at once have seen its value. If you desire to raise stock quickly, the best way is to remove all flowers at once, and give the plants a slight mauling of loam and old manure. Water this thoroughly about the stems. By the end of September you may start taking cuttings, inserting these in sandy soil in any handlight or frame, and plant out in April ensuing in rich, well-prepared ground. By growing these young plants well during the summer of 1903, good tufts full of buds should result in the early autumn of that year, when your best way of bringing the variety into notice would be that of exhibiting, say, a half-dozen or dozen pots of it in flower before the Royal Horticultural Society. By entering the variety (which must be named) for certificate it would come before the floral committee of that body, who adjudicate on all new plants of this kind.

Propagating Tufted Pansies.—Will you kindly tell me the best time and way to strike cuttings of these? I have read you ought to take them from cuttings without hollow stems. I have often tried to strike them, but cannot succeed, and I can never find them without hollow stems. I tried them under a handlight, in greenhouse, and in cold-frame. Will you tell me also what soil?—J. LIZARD.

[The best way of securing stock of these plants is to plant a few reserve clumps in the border somewhere and treat as follows:—When the first flush of bloom is past, or say at the end of June, cut the plants closely over to within an inch of the soil or thereabouts. At this time the base of the plant is crowded with fresh young shoots that cannot grow by reason of the crowded tuft above, but with light and freedom quickly take on a fresh lease. After cutting down, lightly fork the surface soil round about the tuft and give a thorough soaking of water. Now obtain fine soil, well mixed with sand, and surround the plant with this to a diameter, say, of 6 inches beyond the

Arundo conspicua at Boscombe, Isle of Wight. From a photograph sent by Mr. W. E. Roberts, High Street, Thirub, Oxon.

some protection in severe weather. The value of well established clumps of these things in the landscape cannot well be over-rated, and both the Pampas and the Reed may be grown without interfering the one with the other.

CULTURE.—The chief items of culture in the Arundo group are a cool rooting medium, and generally a rather moist soil. Where a deep bed of moist loam exists, there will the Arundo be found most vigorous, the plants attaining to 10 feet or a dozen feet high when in flower. Like the Pampas Grass, these Arundos may be raised from seed and the plants increased by division. The seeds may be made the more reliable if at flowering time the heads are shaken together freely every day for a short time. Arundo seed is also more reliable as a home-saved crop, because of an earlier flowering and with greater sunlight to ripen it. The following are the best kinds of this small genus:—

ARUNDO CONSPICUA (New Zealand Reed).—No word description will give so clear an idea

forming a compact panicle a foot or more long. The growth is free and very vigorous. It has been known in British gardens nearly 300 years. Native of South Europe.

A. DONAX VERSICOLOR.—This is also called A. D. variegata, and may best be described as a dwarf variegated form of the last-named kind. Although not reaching the same fine proportions as the type, the plant is singularly effective, and in this respect superior to the original plant. The broad, handsome foliage is strongly ribboned with silvery-white, hence the striking effect of a well established clump. In the winter it is well to cover the ground, crowns, and tufts with Cocoa-nut fibre or coal-ashes to a depth of quite 6 inches, as not infrequently a sharp spell of frost may injure the coming reeds.

E. J.

NOTES AND REPLIES.

Violets in poor condition.—Kindly tell me what to do with the violet-plants from which the enclosed have been taken? The plants seem to have deteriorated

tuft, also sprinkle some of the same soil in the centre of the plant and presently wash it down with water from a fine-rose can. For a time, if the weather be dry, continue to sprinkle the plants daily each evening with water. By following this carefully the fresh growths in the centre will root into the new soil, and may, a month after the cutting down, be detached and treated as cuttings, though, in this instance, these will be mostly "really rooted ones." These young unflowered pieces you may either insert in a frame as cuttings, or, by leaving a fortnight longer, make up a border of good soil in a shady spot and transplant them there. This method produces the finest plants with a minimum of labour, and where large numbers are required from a plant or two it is best to first pull out the more prominent growths and repeat this operation as the cuttings are fit for removal.]

GARDEN WORK.

Conservatory.—Fires may be discontinued now, as when fires are used late in the season there is a danger of more heat than is necessary being present, and this leads to weakly growth and more trouble with insects. Ventilation must be carefully given. There has been a long continuance of north-east winds, and while these last the ventilation should be on the south side only. Shade will be necessary, especially for small houses where there is not much room for climbers. Though there is usually a set time for watering, at present generally in the morning, yet some plants will require watering more than once in the twenty-four hours, especially *Spiræas*, *Hydrangeas*, and *Pelargoniums*, which have consumed most of the food in the pots, and are now either in blossom or the buds are beginning to expand. Liquid-manure will be a great help to all such things now. Those who have a suitable tank may make their liquid-manure at home, and save the expense of artificials. There is no better stimulant for flowering or fruiting plants than the drainings from a farmyard where a number of well-fed animals are kept. Among the chief plants in bloom now are *Roses*, *Azaleas* (later sorts), *Pelargoniums*, *Heliotropes* (some of the new sorts have very large flowers), *Hydrangeas* (white and pink); a blue tint may be imparted to the pink flowers by mixing iron filings with the soil or by watering from a tank in which rusty iron is kept. The same tint has been obtained by growing the plants in peat; but *Hydrangeas* require a soil with more body in it than is usually found in peat to produce large trusses of bloom. *Fuchsias* are coming into bloom, and will do much to take off the stiffness of the *Hydrangea* and *Pelargonium*. *Lilies* of various kinds will come on in succession. The time of forced shrubs is now pretty well over, and the plants should be moved to another house to complete their growth, and when the young wood is getting a bit firm the plants may be plunged outside. We generally plant them out to save watering. The roots never wander far away, and those showing plenty of buds may be lifted any time for forcing again. *Palms* may be repotted now if necessary, or be helped with stimulants.

Stove.—Mixed collections of *Palms*, *Ferns*, and flowering stuff must have a thin shade when the sun is bright. Even *Dracenas* and *Crotons*, which require strong light to colour the foliage, will suffer if exposed to very bright sunshine. The best place for the plants which require light to put on colour is a span-roofed house running north and south, where the shade may be moved round as the sun changes its position, or rather, as the sun is a fixed body, when its influence bears on any particular side of the house. The smaller the house the more need will there be for shade, and the moisture should be used freely on floors and stages to keep the atmosphere genial. The suitability of the house for any class of plants has a good deal to do with successful culture. Shift on *Caladiums*, using rough fibrous stuff for the last shift. The drainage must be very free, as these large-leaved plants require a good deal of water with some stimulant in it when the roots have filled the pots. Continue to put in cuttings of *Peonies* and an

plants of which young stock is required. Nearly every cutting will strike in a brisk bottom-heat if kept close and shaded. Rooted cuttings should be lifted out of the bed, and when hardened a little, potted off, still keeping the little plants warm and close till some progress has been made. Night temperature, 60 degs.; air to be given at 80 degs.

Tomatoes under glass.—Tobacco-houses may be planted now that the bedding plants can be taken out. Sweet loamy soil is the best for Tomatoes. A little soot and lime may be mixed with it to check any fungus spores which may be in the soil. It is not wise to plant Tomatoes in the same soil more than two years. We generally open trenches a foot wide and the same in depth, and fill in with fresh stuff. Of course, some advantage would doubtless be found by clearing all the soil out, if time could be found for the work, but our system of trench planting has so far answered very well; but there is not much in Tomato growing now, anyway. Trim the plants to single stems, and keep all side shoots rubbed off when small. Give no stimulants till the two bottom trusses are set. Tomatoes do best in a fairly brin soil. A top-dressing later on will encourage surface roots and save labour in watering.

Roses under glass.—Insects will give trouble now, and mildew may appear on the foliage if the roots have received a check either from drought or if too much water has been given. My opinion is, the greatest source of mildew arises from the check given by drought, especially in the case of *Marechal Niel* or other *Roses* planted in the border. There are several remedies for mildew, of which sulphur in some form is the chief ingredient, but no remedy is really effective until the cause has been discovered and removed. Cuttings of forced *Roses* will strike with almost absolute certainty in bottom heat if kept close and shaded. If the cuttings are laid in a bed of warm, moist *Cocca*-nut fibre, roots will form in a short time, and, when the roots are a quarter of an inch long, pot off and keep close and warm till established. An old leaf bed which has been used for propagating other things will do very well.

Orchard-house.—More water will be required now. Keep out cold north-east winds and give air all along the ridge and on the south side, syringing twice a day if the water is soft, and close not later than four o'clock, to make as much use as possible of the sunshine. Give an inch or so of air at intervals along the ridge about eight o'clock in the evening, unless cold and frosty. Continue dislodging, and thin the young fruits a little if much crowded.

Window gardening.—Do not be in a hurry to place tender plants outside; but they will be quite safe in a cold-frame, and to this extent the windows and spare room may have their plant occupants thinned. Plant all bulbs which have flowered, out in the garden. *Lilies* of the *longidorum* and *auratum* types will do very well in a light window. Dust a little Tobacco-powder in the centre of the plants if there are green-fly. A good fumigating apparatus may be made with a few thin Bamboo canes or wires covered with calico or an old sheet. This can be placed over the plants on a table and the Tobacco smoke puffed inside. Five minutes will do it. *Pelargoniums*, *Calceolarias*, and *Cinerarias* are beautiful window plants, but the flies will give trouble.

Outdoor garden.—The late cold winds will check growth and increase the number of insects, which must be dealt with promptly. The outdoor garden wants rain to bring up seeds and remove the stunted appearance of the young shoots exposed to the biting north-east winds. A south wind and warm showers would help things immensely. Tufted *Pansies* are among the brightest things in the garden now, especially where the beds have been well prepared. In dry, porous soil a layer of cow-manure 8 inches or so deep in the beds will be a great help to the plants when the hot weather comes. Charred garden refuse passed through a ½-inch sieve to remove stones, etc., is the best dressing for the beds after the spring flowers are removed to prepare the soil for the summer hedges. There is yet time to strike cuttings of coloured-leaved plants in warm-frames. Such plants as *Colcuses*, *Iresines*, and *Algeria* may be easily raised by the thou-

sand in warm-frames. They will not be wanted till the weather is warm in June, and for effective massing they must be thickly planted. Mulching and watering must be freely used for transplanted evergreens. Damp the foliage occasionally in dry weather. Dust a little Tobacco-powder among *Roses* on walls. If there are no insects now, there will soon be plenty if nothing is done.

Fruit garden.—When *Grapes* are colouring the ventilation should be increased, a little air being left on all night; but there should be no lowering of the temperature, neither should the borders be permitted to get too dry. Sub-laterals will not give much trouble if they have hitherto been kept within bounds. New varieties may be planted at any time during this month or later, when the young Vines are ready. If the eyes have been started in sods, they will be ready to plant when a foot or so high, as then they will be making roots freely, and will start away strongly if planted in a good border inside and helped on with warmth and moisture. The thinning of late *Grapes* will now be in progress, and, if the fruit is expected to hang late, the bunches must be well thinned so that the air can circulate among the berries. After thinning, top-dress the borders with some good artificial manure that will act quickly. The late spell of cold, windy weather will produce an influx of insect life that will give trouble if not dealt with promptly. Many owners of moderate-sized gardens are investing in a spraying implement for destroying insects, and, as soon as the blossoms are set, it should be brought into use and kept at work until the trees are clean. The covers may be taken from the Peach wall as soon as the weather is settled.

Vegetable garden.—Thin young crops of vegetables, such as *Onions*, *Carrots*, *Pan-nips*, and *Beet*, in good time. *Beet* transplants well if carefully done, and the hole made deep enough to receive the roots without injury. One good watering after transplanting will generally suffice. Salt is a good dressing for *Seakale*, *Asparagus*, and *Beet*, but not for *Potatoes*. It may be used any time if half a pound per square yard is not exceeded. *Windsor Beans* may be planted for a late crop, and *Kidney Beans*, both dwarf and Runner, should be planted freely, and the Runners will pay for long sticks. In sticking *Peas* let the sticks slope in opposite directions, and not be thrust in too close at the top, otherwise the *Peas* will grow out of the sticks instead of growing up between. Make a good use of north borders for *Cauliflowers*, *Lettuces*, *Turnips*, etc. Earth up early *Potatoes* in good time. Before earthing up, a sprinkling of gnatso may be given if necessary. When the *Potatoes* are cleared out of frames fill them with *Cucumbers* or something useful. *French Beans* bearing in warm frames must be gathered as soon as fit for use to insure a succession, and liquid-manure should be given. Remove all flower-stems from *Rhubarb* and thin the crowns of *Seakale* just breaking into growth. Plant *Calhages* to come in end of summer and during autumn. E. HODDY.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

May 19th.—Bedding plants are all in cold-frames hardening, with the lights or other covers off during the day. Hardy things, including *Calceolarias*, *Pentstemons*, and *Antirrhinums*, have been planted out. Late cuttings of coloured-leaved plants are still kept warm, especially at night. Hardy annuals sown outside which are large enough have been thinned freely. Standard and dwarf *Roses* budded last season are growing freely, and supports have been placed to the shoots to prevent injury from wind.

May 20th.—Dressed terrace and other gravel walks with weed killer. This saves all further trouble during summer, and the walks are always firm. The roller is used after rain. *Deutzias* after flowering have been cut back and placed in warm-house to break and make growth. Repotted *Azaleas* and *Epicurises* which have been cut back, and are now breaking freely. Only the best fibrous peat and sand have been used, and the soil is made firm.

May 21st.—We have made a beginning to plant flower garden; the plants are well hardened and will take no harm. We have a good deal to do, and are compelled to make an early start. The beds which are filled with spring flowers will not be ready till the middle of June. Some of these will be left for sub-tropical and other tender things, and the plants will be large when put out. Thinned late Grapes. Removed covers from wall trees.

May 22nd.—Sowed Antocrat and Ne Plus Ultra Peas. Sowed more Lettuces and planted out previous sowing. Earthed up early Potatoes and thinned Carrots and Parsnips. Dusted root over Onion-beds. The hoe is used as freely as possible. Tobacco-powder is our remedy for insects on wall-trees. The distributor is always charged with it and kept at hand. Special attention is given to disbudding the young shoots of Peaches and other trees with crowded shoots.

May 23rd.—Planted Cauliflowers on north

INDOOR PLANTS.

VINCAS.

(REPLY TO "F. G.")

THE three varieties that have been under cultivation from time to time here and there amongst hothouse plants are each deserving of more extended notice than they receive. More often than not they are badly managed during growth, whilst they are not the easiest of plants to keep safely through the winter season. I have seen plants of these Vincas trained upon trellises, a mode of culture that is out of all character with their requirements. The growths in such cases are tied in at intervals, and but rarely are the shoots increased in numbers, whilst the flowers upon these long shoots are never so fine as they should be. It is no trouble whatever to flower the plants continuously through the summer. Then having done good service in this way, towards the autumn the shoots with flowers upon them can be cut for other uses, and thus prove of good service.

after each shoot has made two pairs of leaves. By non-attention to pinching only a few shoots will push away, with the result that the plants are considered of bad habit. The last stopping should be done all at once, and in six weeks' time the first flowers will be opening. During the growth one additional shift, if not two, should be given. The first one will be by considerably reducing the old ball in the same way as Pelargoniums are treated in the autumn. The

Soil best suited to these Vincas is light loam and leaf-mould, the latter being worked through a sieve; some manure from a spent Mushroom-bed would be an assistance in after shifts, and in any case being used freely. The potting need not be done so firmly as in the case of permanent shifts. As the plants get into free growth with good root-action, they will take water very freely. When the plants are in bloom close attention must be given to the removal of falling blossoms, and during the flowering period liquid manure may be given at each other watering. As soon as the blooming season is over, the plants should be kept fairly dry until starting time comes round again.

The most useful perhaps of the three varieties under cultivation is

V. ALBA OCELLATA; its pure white flowers, each with a bright rosy eye, are very showy and attractive, and freely produced under good cultivation.

V. ALBA is a pure white variety, with the faintest trace of pale yellowish-green frequently seen in the eye; the foliage is also of a paler shade than in either of the other two kinds, whilst the growth is not, on the whole, so vigorous. This is quite in contrast with some flowering plants in this respect: the white Lapageria, for instance, is frequently a more vigorous grower than the red variety.

V. VASEI has pale rose-coloured flowers with a darker shade of the same colour at the eye; this is as vigorous a grower as V. alba ocellata, with darker and somewhat more hirsute foliage. Each of these varieties is well worthy of cultivation, being quite distinct one from the other. Those who have light houses at their disposal with plenty of room therein may do far worse than grow these free-flowering plants. In the winter season they require but little room, for by semi-pruning late in the autumn a considerable reduction can be made in this direction. GROWER.

NOTES AND REPLIES.

Genistas after blooming.—Would you kindly tell me how small Genistas ought to be treated after they have flowered to ensure their doing so another year? I have had one in a large pot, which flowered for two years, but has this year not one blossom on it. It has not been repotted. Is this the reason?—S. G.

[Genistas should be cut back directly they have done flowering, and as soon as the young shoots produced after this operation are from $\frac{1}{2}$ inch to $\frac{3}{4}$ inch long is the time to repot them, after which, do not expose them to direct draughts for a week or two, till the new roots take possession of the fresh soil.]

Balsams in pots.—I have sown some Balsam-seed in pots, and am not sure if the plants should be always kept in the greenhouse or in a cold frame. They are about 1 foot high now. I would be much obliged if you would tell me how to treat them?—R. J. H.

[Prick off into small pots when large enough, keeping moist and near the glass. Shift on when these small pots have become filled with roots, using this time a little rotten manure mixed with the soil. Finally, put them into 8-inch pots if you wish to have large plants. Air must be freely admitted to the house in which Balsams are grown, care being taken that the plants never suffer from dryness at the roots. A little weak liquid-manure occasionally will do much good. Above all things, see that the plants have plenty of room and light, and do not attempt to force them into bloom in any way, otherwise they will become very weak and leggy and the flowers will be poor.]

Ferns and plants for winter bloom, etc. (Blackton).—This is a rather unusual mixture, but you may obtain flowering plants by extending your list of Orchids, and by growing Cypripedium insigne and Masdevallia tovarensis secure two of the surest of winter-flowering subjects. It is quite possible you may succeed in flowering Begonia Gloire de Lorraine, B. insigne, Tree-Campanulas in

Vinca rosea.

under. Sowed more Turnips. Sowed a few seeds of several kinds of late Broccoli. We have had no trouble with the Gousberry caterpillar for years; nevertheless, a look round given from time to time while the moths and saw flies are about. Commenced spraying Apple trees, for eggs of the Codlin-moth are now being laid on the young Apples. Looked over climbers in conservatory to regulate growth.

May 25th.—Formed groups of Zonal Geraniums and Tuberosus Begonias in conservatory. Aram Lilies which flowered early have been placed outside to ripen, and the space has been filled with a bold group of the Trumpet Lily, which is now flowering freely. The double Tiger Lily does well in pots, and may be forced on gently. Vaporising must be done when necessary, as flies are foul of Lilies, creeping into the heart of the plants, and soon doing much harm if neglected.

CULTURE.—Propagation is easily effected either by seeds or cuttings. The present is about the best time for striking cuttings or for purchasing young plants to grow on. It is always advisable to have a few young plants on hand, as the old ones have a disposition to die off after a few years' growth. This failing, however, is quite immaterial when the younger plants can be so readily grown on to supply their place. My plan has been to prune back into the hard wood somewhat in the same way as when dealing with good-sized plants of the show or fancy Pelargoniums. In this way a good foundation can be laid for a bushy plant; those grown upon trellises I should imagine are never so treated. As soon as the young shoots are 3 inches or 4 inches in length pinching should commence, taking all the stronger ones first. This stopping of the shoots should be persisted in until a good bushy habit is the result, and it may be done

variety, with pots of Daffodils brought in from time to time to keep up a succession. Such varieties as obvallaris, Golden Spur, the old Double Yellow, Horsfieldi, Empress, ornatus, princeps, Emperor, Stella, etc., may be grown in pots in soil, or in fibre and shell, in water, ornamental vases, or bowls ready for the table. Crocuses and Snowdrops, also Snowflakes, may be similarly treated. Azaleas of the mollis and indica sections would also open in such a temperature, and those named are but little troubled with insect pests. Of Ferns, you may grow many Pterises, also Asplenium bulbiferum and A. Hillii. Another good Fern is Invalia canariensis. There are many others that could be named, but we have no information as to any facilities you possess for growing plants at other times; therefore our list is of those requiring but a minimum of culture under glass.

Celsia Arcturus.—I have grown this charming plant for the first time this year. I think if it were better known many persons who possess a cool greenhouse would find it a valuable addition to their number of easily-grown plants. The seed was given me last July, and was sown in a box plunged in an ash-bed. In October the seedlings were potted, then watered in a cold frame. Each has been brought into a cool greenhouse as the flower-spike shot up, and when in bloom has been moved to a warm sitting-room, the dry atmosphere of which does not seem to affect it in any way. The plant is about 26 inches high, in a 4-inch pot, and blooms the whole way up the stem; each flower is a bright yellow, with a reddish bee-like centre, many of the individual blossoms being nearly 2 inches across. I am told that the Celsia, if repotted when it has done flowering, will improve the second season. Perhaps some other reader of GARDENING who has been equally successful will give his experience of this graceful plant?—G. M. SANDARS, Lincoln.

VEGETABLES.

LATE PEAS.

SOME varieties of Peas are naturally late, as others are naturally early, even if all be sown at the same time. Late sown Peas of any variety, whether naturally early or late, are called late Peas because required to pod late. It is comparatively easy to grow early and mid-season Peas, but late ones do not always result satisfactorily. Sown late they have to face hot, parching weather, which is severely trying. They are too often sown too thickly, and, not least, are as often sown on ordinary prepared ground, which has not been deeply cultivated and well manured. Without doubt, very fine late Peas are Sharpe's Queen, The Glandstone, and Late Queen, each some 3½ feet to 4 feet in height, but even these will not produce remunerative crops if not sown thinly in deep trenches heavily manured, or on ground that has been deeply trenched throughout. A heavy dressing of manure, if of a half decayed and wet nature, buried well down, is of the greatest value, as not only does it entice roots deep out of the hot surface soil, but it also furnishes plant food and moisture. It is in the latter respect that animal manure always exercises an influence in plant growth in dry weather that artificial manures, which are really moisture absorbents rather than imparters, cannot supply.

Recently, at Forte Abbey, I observed that for Peas, drills, or rather shallow trenches, were opened with a spade, thus making them some 8 inches wide. In such case not only can the Peas be, but they were there, both thinly and evenly sown over the bottom of the trench, thus allowing to the plants ample room. That is much better than is the too common method of sowing thickly in a narrow bottomed drill, which causes seed and plants to crowd each other. Late Peas, apart from having to surmount the troubles incidental to root drought, also have to face insect and fungoid attacks, and these pests too often render all cultural labours useless. Thrips, singularly tiny insects, prey upon the leaves and flowers, sucking their juices and rendering them useless for good. In other cases mildew seizes upon the plants, and, commencing on the

older leafage low down, gradually creeps upwards until the whole of the leafage is white with the mould. When that stage is reached the condition of the plants is usually hopeless. To counteract these insect and fungoid troubles Mr. Crook has been for several years employing various patent liquids, especially Abol and Spimo. These made very weak, and using an Abol or spraying syringe, are gently sprayed over the Pea rows even ere insect or mould is seen, and in that way, by giving occasional sprayings later, have done wonders in keeping these pests at bay. Those who want tall Peas and will treat the ground well and sow thinly, as advised, should also arm themselves with some such insecticide or fungicide, and use it weakly but occasionally on their plants. It is only by persistently battling with such pests crops can be saved. A. D.

NOTES AND REPLIES.

Young Nettles as food.—In reply to query about young Nettles by "North Wales," in last week's GARDENING, young Nettles should be cooked like Spinach, and are very nearly as good.—A. P.

—Here, in Lancashire, young Nettles are eaten. Some people make porridge of them by boiling them, afterwards chopping them up and mixing pepper and butter with them. Thousands of gallons of beer are made from Nettles.—S. STRAZAR.

Cucumbers, stopping.—I propose to devote a greenhouse (span-roof, 15 feet by 10 feet) to the growth of Cucumbers for this summer. I should be so glad if you will give me a few simple hints as to stopping and training? When I have tried it before I got an uncontrollable mass of foliage.—EMILY McWILLIAMS.

[Grow your plants quickly, and do not stop them till 5 feet of growth is made. The training consists in stopping the laterals at the third joint so soon as the best growth is fully developed, and do not allow any more growth from the last eye, but encourage sub-lateral growth from the first joint if possible. In this way your plants will be kept well furnished near the stem. The roof wires should be 6 inches apart and 9 inches from the glass. You must pay strict attention to such details as watering, top-dressing, and the like if you wish to succeed.]

BIRDS.

Death of a hen Canary (H. M. Batson).—This bird had suffered from egg-binding, resulting in rupture, which caused speedy death. Egg-binding is frequently brought about through excessive fatness, sometimes from the egg being soft and shell-less, and at other times through cold, searching weather at the time of laying. Care should be taken to prevent breeding hens becoming too fat, also in supplying them with lime in the form of old mortar powdered fine, or ground oyster or eggshells, to enable them to elaborate hard shells for their eggs, and that they be kept from draught. They should also be allowed a liberal supply of green food to prevent constipation at the time of laying. Some forms of egg-binding are curable by the use of castor-oil, but the form from which this bird suffered always proves fatal.—S. S. G.

LAW AND CUSTOM.

Arrangement to surrender tenancy.—A tenant of a £30 house, wishing to leave, asked me, as landlord, in February if I would oblige him by letting him quit any time between then and the end of May. I agreed to do so. In the event of his not quitting, as by agreement, could he legally stop on and leave in September next if he so chose? Nothing beyond this agreement made in February has taken place, and no written notice given on March 24th to quit in September. The house was taken in the end of October, 1899, and rent paid December, March, June, and September of each year (first rent, broken rent to December). Consequently, I presume March 24th would be date to give notice on either side?—J. H. S.

[No written agreement for the surrender of the tenancy having been entered into, you cannot compel your tenant to quit, and he may remain in possession if he chooses. No notice to quit having been given, the tenancy will not determine upon September 29th, but it will continue until determined by notice to quit or by arrangement. A notice to quit need not be in writing, although it is always wise to give it in writing. If there be no written agreement of tenancy it will be presumed, if the rent receipts be merely made out for a quarter's rent, and no evidence to the contrary be forth-

coming, that the year of tenancy runs from December 25th, broken rent having been paid up to that date. Cases have been actually decided thus, but the decision seems questionable, so far as yearly tenancies are concerned.—K. C. T.]

CORRESPONDENCE.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow these rules: All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF GARDENING, 17, Farnwell-street, Millers, London, E.C. Letters on business should be sent to the PUBLISHER. The name and address of the writer are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper, and not more than three queries should be sent at a time. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, queries cannot always be replied to in the issue immediately following the receipt of their communication. We do not reply to queries by post.

Naming fruit.—Readers who desire our help in naming fruit should bear in mind that several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruit for naming, these in many cases being unripe and otherwise poor. The difference between varieties of fruit, in many cases, so trifling that it is necessary that three specimens of each kind should be sent. We can undertake to name only four varieties at a time, and these only when the above directions are observed.

PLANTS AND FLOWERS.

Moving Daffodils (Robt. J. Hill).—Lift your bulbs in July when the foliage has ripened off. After drying them slightly but thinly spreading out on a hard surface, replant in August in a fresh site which has been deeply dug. Plant the bulbs so that room for development for some time may exist.

Justicia speciosa (Cheiston).—Cut down at once, and directly the old plants break into growth after having been cut down shake out and repot in a compost of 2 parts loam to one part leaf-mould and decayed manure, with a sprinkling of sand. When the roots get bold of the new soil they may be moved to a cooler structure, giving the plants an occasional dose of liquid-manure.

Watering Cacti (F. G. H.).—During the winter months, while Cacti are resting, very little water should be given. When in summer growth begins, they must be kept fairly moist at the roots. If they are growing in a compost partially composed of old mortar-rubbish, and the pots are well drained, there is no fear of their becoming waterlogged. No water should be allowed to stand in the saucers if the Cactus pots are stood in them.

Moss on soil in pots (Navy).—You evidently have very porous pots—all the better for your plants—do keep the surroundings a little too moist, or else your plants are in a shady position. You cannot kill the Moss on the surface soil of the pots without injuring the plants. If you were to stir the surface of the soil occasionally, it would not grow. It seems very strange that, although you cultivate the soil in the open-air garden, few people consider it necessary, and at the same time very beneficial, in the case of plants grown in pots. If you were to wash the pots now and again there would be no Moss on them.

Keeping Primula seed (M. May).—Yes, the seeds will keep quite well for a year. Place what you wish to keep in the ordinary seed pocket, fold it, and insert in a glass bottle or tin that can be stoppered. Filling the phial, a tin box will do as well for this short term, placing the vessel in a quite cool place where the conditions are as uniform as possible, without any suspicion of damp. In this way we have kept Primula seed for six years, at which time it germinated to at least 90 per cent. in about three weeks from sowing. In sending queries, kindly write on one side of the paper only, putting the various queries on separate sheets.

Raising Dahlias from seed (C. Andrews).—I ought to have sown your Dahlia seed in March by preparing some shallow pans, placing some crocks in the bottom, and filling up with sifted soil, consisting of one part leaf soil, one part leaf soil, and one part silver sand. Let the soil give a good watering, then sow the seed thinly, covering over with some of the same compost. Put a square of glass on the top and place in a greenhouse, and if a little bottom heat can be given, so much the better. When seedlings are large enough they should be potted off into small pots, after hardening off in cold-frames, planted out at the end of May or early in June.

Bouvardias (Joseph Smith).—In growing Bouvardias in pots, it is important that they be propagated as early in the year as possible. They should be potted on in March, required in light, porous soil, and grown on in warmth during the early part of the season. Later on they will do well in cold-pits, the lights being taken off in favourable weather. Stopping the plants requires special attention. Although Bouvardias enjoy hot, dry weather, they must never be allowed to get dry at the roots, and the syringe should be used freely in order to check the attacks of insects. Keep root-water, when the flowering-pots (6-inch) are full of roots is a good stimulant for them.

Azalea indica falling (Mrs. Murray).—In all probability your Azaleas need repotting. Turn them out of their pots and remove the crocks from the bottom of the ball, and as much of the old soil as you can. They should be repotted, using for the purpose pots that will allow a space of an inch or a little more between the ball of earth and the side of the pot. Good fibrous peat, broken up, and mixed with a fair sprinkling of silver-sand, is a suitable soil for Azaleas, and good drainage must be ensured. In potting, ram the soil very firmly. As to this, keep in a structure warmer than an ordinary greenhouse, and syringe the plants frequently in order to encourage a vigorous growth, as upon this the future display of bloom depends. When the growth is completed, or nearly so, more air must be given, and during the latter half of the summer the plants

... be stood out-of-doors, so that the wood may be thoroughly ripened. If your plants do not need repotting, keep them warmer, and syringe as above advised, watering them about every fortnight during the growing season with a mixture of soot and manure-water considerably diluted.

Mutisia decurrens (*D. Wardrop*).—What this plant really needs is shade and moisture. It is not essential that the stems and growths generally shall be in the shade, but it is important that the roots may be so protected that a cool and uniformly moist root run is maintained. No better place for the Mutisia could be found than a Rhododendron-bed which is well attended to in summer as regards watering, as this would just suit the growing season of the plant. A good compost in which to grow it is peat, with about one third of loam and plenty of sand. We know of some plants in your district (Edinburgh) that have stood out-of-doors for five years with no protection, and which have flowered well.

Asparagus Sprengeri (*A. Suberiber*).—This, during the summer months, will succeed perfectly without any artificial heat whatever. At the same time, it must be shaded from the sun, and is greatly benefited by being syringed overhead occasionally. In the winter it is all the better for being kept in a somewhat warmer structure than an ordinary greenhouse—that is, a minimum temperature of 45 degs., rising 10 degs. to 55 degs. Established plants will keep in good condition in a dwelling-house throughout the greater part of the year. When young, and it is desired to push the plants on as quickly as possible, they may be grown in a stove temperature, and in this way they make more rapid progress than under cooler treatment. They can, of course, be hardened off afterwards.

Preparing bedding Begonias (*Rachel Stephenson*).—Many failures with bedding Begonias are due to cooling the soil in the early stages of growth. Occasionally excellent beds are met with in amateur gardens, and their culture, as a rule, started into growth very gradually, perhaps in a cold-frame. Cocoa-nut-fibre for embedding the tubs in when starting them in spring is very useful. The new roots lay hold of it readily, and the tubs can be planted with a portion of it adhering to them. Even when cool treatment is given it is not wise to start the combs too early, as if only a inch of growth has been made when final planting takes place, they go away strongly and make up for what some might consider lost time, and both the quantity and quality of the blooms are better. Leave young as they are, and, if all goes well, you will have fine strong, well-rooted plants to go out about the middle of May.

Deutzia failing to bloom (*E. S.*).—Deutzia gracilis, when grown under glass, is very liable to behave in the way described. Plants that are lifted from the open ground in the autumn, potted, and taken under glass, are particularly liable to do this, while a check occasionally sets in in the same manner. When established in tubs they seldom give trouble. In this respect unless they are allowed to get too dry at the roots or experience some other check. Deutzias that have been forced or flowered in the greenhouse should be gradually hardened off, so that when all danger from spring frosts is over they may be stood out-of-doors. At that time any old and exhausted wood should be cut out, in order to allow of the development of young and vigorous shoots, while the plants may be potted if required. On this point, however, it may be borne in mind that they will stand for years in the sun and pots and flower well each season, provided they are occasionally watered with liquid-manure during the growing period.

Moss on lawn (*Mrs. E. Oldham*).—Sulphate of Iron has been strongly recommended for destroying Moss on lawns, the average quantity to be used being 6 lbs. per 100 square yards. The best way to use the sulphate is in solution, thus distributing it evenly. The solution is made in the proportion of 1 lb. of the sulphate to 3 gallons of water. It should be made in a wooden vessel, such as an old cask, and, if possible, with soft or rain-water, and also just before it is used, as it loses strength by keeping. The sulphate can be applied at any season of the year, and is known to be acting effectively when the Moss turns black, after which it withers away. If the application has been too weak the Moss only turns reddish, and after some time recovers itself. In this case a second application will be needed. It sometimes happens that the first two applications are insufficient, and the operation has to be repeated the following year. As Moss generally indicates pooriness of the soil, it is advisable after the Moss is destroyed to apply some rich top dressing, such as wood-ashes, loamy soil, and well-rotted manure mixed together.

TREES AND SHRUBS.

Moving a Myrtle (*F. J. L.*).—The best time to remove the Myrtle is directly the drying winds of March are over, though if it has not yet begun to grow you may move it now. When replanted, see that it is watered thoroughly, and take care that it does not at any time suffer from drought.

Amgdalus nana (*F. P.*).—This, the name of any plant, has much to recommend it, as it is very early in flowering and very dwarf in habit, rarely exceeding 3 feet. The colour of the flowers is deep rose, and they are produced in great profusion. For planting near the margin of shrubberies it is admirably adapted, and deserves to be better known.

Dying trees and shrubs (*Ignoramus*).—Without having seen your long-neglected garden before it was destroyed, it is difficult to give any advice, but if the trees and shrubs to which you refer are looking so badly, say, 10 inches to 12 inches thickness of soil put about them, that would certainly do harm, whereas but a top-dressing of 3 inches or 4 inches should have done good. With respect to the dead trees and shrubs that were transplanted, it was likely such death would result, knowing that they had not been moved for so many years, and had grown large and wild. In lifting them, the roots would have to be severely reduced, and the trees must necessarily suffer in consequence. It would have helped them had the heads been hard cut back also, as also would have been occasional deluges of water. Evidently, under the conditions which you called, the transplants of large trees and shrubs which was a mistake, and the fact that the latter was generally hot and dry, and in the process of very trying to transplanted shrubs.

FRUIT.

Peach-leaves turning yellow (*G.*).—Your Peach-trees are evidently suffering from lack of proper root-food. Get some artificial-manure, such as a mixture in equal parts of basic-slag, bone-dust, kainit, and sulphate of ammonia, and if you could add to this three times its bulk of wood-ashes and some lime-rubbish, then straw it about the border at the rate of 6 oz. per square yard, well raking it in and also watering freely, great good should result. You should also see that the ventilation is well attended to.

Peach-leaves blistered (*Major*).—Yours is a bad case of Peach blister, a disease from which in cold springs few outdoor trees escape. It is the product of a fungus, though doubtless generated by cold winds or frosts causing disruption of the cellular tissues of the leaves, which are just then very tender. Trees under glass never suffer from this trouble. Peaches are usually grown on warm walls, and the position naturally creates early growth. Then we get, from warm, sunny days, changes to frost or cold, biting winds which injure the leafage. The best remedy is found in gathering the affected leaves gradually, taking the worst first. Spraying the trees before the leaf-buds open with the Bordeaux-mixture or sulphate of copper solution also does good.

Decaying Apple-trees (*Chiltern*).—You had better lift your two bush Apple-trees in the autumn and replant them, make holes 4 feet across, throw all the top good soil out on to one side, and the bottom poor soil on the other; then throw the topsoil into the bottom of each hole, and bring other fresh soil—the best you can get—into and nearly fill each hole, then replant. If any of the roots are coarse or woody, and especially go downwards, cut them partially back neatly; also cut off the decaying tops of the branches. Add a small quantity of well-decayed manure to the soil when you plant, also wood-ashes. Top-dress or mulch each tree over the roots with long manure. For your soil, if you plant other Apple-trees, get those worked on the broad-leaved or Paradise-stocks. Treat each new tree in planting as advised for the old ones. After three years, a trench, 2 feet wide and deep, should be opened round each of those boles, and some manure added. The trees should then do well. Specially give them a mulch of long manure, 3 inches thick, during the summer.

SHORT REPLIES.

Wm. Shaw.—See issue of March 31, 1900, p. 58, which can be had at the publisher, price 1d., post free. **H. W. E.**—Write to the Superintendent of the Gardens at Hampton Court Palace, Middlesex.—**H. D.**—See article on Montebretias, in our issue of March 22, 1902, p. 44, which can be had of the publisher, price 1d.—**R. J. H.**—See article and illustration of Margaret Carnations, in our issue of April 10 of this year, p. 58.—**Greenmont**.—See reply to "Anatone" re *Prinnia obconica*, in our issue of May 10, p. 140.—**Mrs. Murray**.—You will find an exhaustive article on the culture of Anem Lilies in our issue of March 30, 1901, p. 55, which can be had of the publisher.—**Res.**—Not common; with care you ought to be able to preserve it.—**Dublin**.—You may fumigate your greenhouse without injuring the Vines, seeing the berries are the size you say. Weak applications two or three nights in succession will be the best.—**Beginner**.

—1, From 40 degs. to 45 degs is quite sufficient. Azaleas had better be stood in the open air during the summer. 2, Hobby's "Villa Gardening," price 6s. 6d., from this office, will answer your purpose.—**E. R. W.**—Apply to Messrs. Haage and Schmidt, Erfurt.—**Mufik**.—See article and illustration of Christmas Roses, in our issue of March 23, 1902, p. 59.—**Anon.**—You will find an article dealing with Begonia Gloire de Lorraine in our issue of May 10, under the heading of "Three Winter-flowering Plants." Tuberous Begonias are summer-flowering, and will not bloom in the winter.—**J. W. Wood**.—Kindly send samples of the fungus you inquire about, and then we will try and help you.—**Dudley**.—Kindly read our rules as to correspondence.—**Geo. White**.—The plant you refer to is no doubt *Campanula isophylla alba*, which any nurseryman in your neighbourhood could get for you.—**C. F. W.**—We have never heard of the Hydrangea about which you ask. Can you send us a shoot?—**Inquirer**.—1, Pull up the seedling Asparagus plants, otherwise they will crowd out and ruin the permanent plants. 2, You can easily take down some of the growths of Clematis montana and layer the same.—**Anxious One**.—See article on "Begonia Gloire de Lorraine," under the heading "Three Useful Winter-flowering Plants," in our issue of May 10, 1902, p. 142.

can easily take down some of the growths of Clematis montana and layer the same.—Anxious One.—See article on "Begonia Gloire de Lorraine," under the heading "Three Useful Winter-flowering Plants," in our issue of May 10, 1902, p. 142.

NAMES OF PLANTS AND FRUITS.

* Any communications respecting plants or fruits sent to name should always accompany the parcel, which should be addressed to the EDITOR OF GARDENING ILLUSTRATED, 17, FURNIVAL-STREET, HOLBORN, LONDON, E.C. A number should also be firmly affixed to each specimen of flowers or fruit sent for naming. No more than four kinds of fruits or flowers for naming should be sent at one time.

Names of plants.—**W. M.**—1, *Adiantum conopseum latum*; 2, *Adiantum gracillimum*; 3, *Pteris cretica*; 4, *Pteris serrulata*. Kindly send better specimens of the others.—**J. B.**—1, *Teucrium triflorum hibernicum*; 2, *Ranunculus amplexicaulis*.—**A. M. Wakefield**.—Several forms of *Epimedium* (Barnwort), *E. pinnatum* and *E. alpinum*.—**Five Year's Reader**.—1, *Peperomia Saundersi*; 2, *Pittonia argyrea*; 3, *Hoffmannia Ghiesbreghtii*; 4, *Pellonia pulchra*.—**Frank Piper**.—1, *Star of Bethlehem* (*Ornithogalum nutans*); 2, *Ribbon Grass* (*Phalaris arundinacea variegata*); 3, *The Mossy Saxifrage* (*Saxifraga hypnoides*).—**G. F. James**.—*Dendrobium fimbriatum oculatum*.—**Crux**.—Specimen too dried up to be able to identify.—**A. W. Brearey**.—We cannot undertake to name florists' flowers.—**Greenoaks**.—*Narcissus Tazetta* Grand Monarque.—*East Dorset*.—*Iris fimbriata* (syn. *I. chinensis*).—**E. M. K.**.—*Karyia japonica fl. pl.*.—**G. G. G.**.—*Pyrus Malus floribunda*.—*Lirely*.—1, *Carex juncus variegata*; 2, *Adiantum gracillimum*; 3, *Poly-podium vulgare cambricum*; 4, *Pteris tremula*.—**Mar. Dale**.—*Tulip La Reine*.—**E. J. P. Edgerton**.—The Shad Bush (*Amelanchier canadensis*).—**Fectia**.—*Tritonia crocata* (syn. *Ixia crocata*).—**Tie**.—1, *Phillyrea Vil-moriniana*; 2, *Olearia Gunnii*; 3, *Double-flowered Peach*.—**Franco**.—Flowers of *Cordylone indivisa*, quite hardy in the South and West of England.—**E. D. Baird**.—*Phyllocactus grandis*.—**Mrs. Hunter**.—Evidently the Puff-ball fungus (*Lycoperdon*). The name is given owing to the manner in which the spores are discharged when ripe.—**No name or letter**.—1, The Spring Snowflake (*Leucojum vernum*); 2, Blue Daisy (*Agathodes caulescens*); 3, Wood Anemone (*Anemone nemorosa*).—**Bunch**.—The Dead Nettle (*Lamium maculatum*).

Catalogues received.—**E. P. Dixon and Sons**, Hull.—*List of New and Choice Plants*.—**Dicksons**, Chester.—*List of Bedding and Border Plants*.—**W. Paul and Son**, Waltham Cross, N.—*List of New Roses*.—**M. Herb**, Naples.—*General Catalogue of Nibbs*.

Photographs of Gardens, Plants, or Trees.—We offer each week a copy of the latest edition of the "English Flower Garden" for the best photograph of a garden or any of its contents, indoors or outdoors, sent to us in any one week. Second prize, Half a Guinea.

The Prize Winners this week are: 1, Mr. Geo. E. Low, 2, Glenageary Hill, Dublin, for *Masdevallia tovarensis*; 2, Miss Norah E. Hay, Tyrrell's Ford, Christchurch, for *Cypripedium Calceolus*.

NOTICE TO ADVERTISERS.

In consequence of the Whitsuntide Holidays we shall be obliged to go to press earlier than the number of GARDENING ILLUSTRATED to be dated May 24th, 1903. Orders should be sent as early as possible in the week preceding to insure insertion. No advertisement intended for that issue can be received, altered, or stopped after the first post on THURSDAY the 15th MAY.

VEGETABLES.

LETTUCES DURING HOT WEATHER.

In many gardens the Lettuce does not receive that consideration it undoubtedly should do, as after the first supply, which may have been raised under glass, or from a sowing in the open air, there is a sudden falling off. The weather, whatever this may be, should not make this difference, as during the hottest weather it is possible to get Lettuce worthy the name. True, it cannot be expected to be so fine as when grown in a cooler season, but sufficiently good enough for my purpose. The Cabbage Lettuce suffers the least from the effects of drought, but in the generality of seasons a good selection of Cos will succeed equally as well. As to which should be grown is a matter of opinion. I grow a part of each. Some varieties, again, are supposed to be better than others through remaining longer before running to seed, but to a certain extent this is a matter of culture, this having more effect upon the well-being of the Lettuce than mere variety. Of late years there has been a great improvement amongst Cabbage Lettuce, being fuller headed, consequently not so flabby in texture. When well grown the old All the Year Round is a capital Lettuce. Growing on poor soil and crowding the plants up together either when sown in beds for transplanting, or when sown where to remain, are the main causes of failure. Whether Lettuce will succeed during summer months when transplanted will depend upon the season, as with the soil dry and with hot sunshine daily for weeks together no one would think of relying upon transplanted Lettuce. Not but that Lettuces transplant much better during the summer months than they generally have credit for. My practice is always to have relays of young plants on hand, and if the weather is suitable for transplanting I do it, but if not, they are thinned out. That some people find a difficulty in transplanting Lettuce during the summer months is not to be wondered at, as the plants are raised so thickly. In consequence they are so tender that they collapse at once.

In raising plants early in the year in boxes under glass, it will be noticed how nicely rooted the little plants are when they have some flaky soil to root into either through the addition of leaf soil or even a little fresh soil. It is the same with plants raised in the open, at least those required for transplanting. When sown to come to maturity where they are to remain, of course this does not matter, although in this case even the preparation for the seed must be thorough, or if the weather should turn out very dry the seed may fail to germinate regularly, especially if on an exposed site. This is all the more desirable on heavy soils, where there is often a difficulty in getting sufficient mould for the roots to ramify quickly into or even the seeds to germinate in. The better course to ensure a succession is to make small fortnightly sowings on the eastern or western aspect, but preferably the former,

as during the hottest part of the day the seed bed would be shaded. Not that this, however, should be from trees, as Lettuces never succeed well when planted in the shadow of either trees or tall buildings. This is by far the best course to pursue during warm and dry seasons, but in cool and moist weather the seeds germinate just as readily if in the open. The seeds should be sown in shallow drills drawn a foot apart, and if the ground is at all lumpy, and some fresh soil or even old potting mould, with burnt garden refuse. Over-night the drills should be watered, the seeds being sown early the following morning. In all probability there will be sufficient moisture retained to ensure the seeds germinating freely; but if not, afford a slight shade by throwing a mat over the bed, having previously watered it. This will be much better than constantly watering and leaving the surface fully exposed to the sun. For sowing direct into the open, so as to remain without transplanting, the site must be in a free working and highly fertile condition. Sow very thinly, crowding of the plants being certainly a disadvantage. Thin early, keeping the hoe well at work being a great aid to growth. The best Lettuces I have are certainly those grown along the ridges of Celery trenches, the soil being well lined down previous to either sowing or transplanting. This would, no doubt, be too dry a site for midsummer crops during a very dry summer, an eastern or western aspect at these times being the better position.

In transplanting Lettuces during the summer, the bed which the plants are to be drawn from must be well moistened over-night, so as to ensure the plants being lifted with all available roots. These must not be drawn roughly, but be gently lifted, or the greater part of the roots will be broken off. Of course, showery weather is the best for transplanting, but, unfortunately, this kind of weather does not always occur at the time the plants are ready for removal. This is easily obviated by drawing shallow drills, these being moistened before planting, a watering afterwards fixing the plants in the soil. If there are not many plants to be set out, I find it a good plan to cover each plant over with an inverted flower-pot for a day or two, removing them at night so that the plants can derive the benefit of the night dews, replacing them in the morning. It may be necessary to water the little plants occasionally until they become well established.

A.

NOTES AND REPLIES.

Houss slops.—What vegetables are those for which house slops are most suitable? Should they be diluted, and if so, by how much?—B. T.

[This should have four times its proportion of water added to render it fit for use as liquid manure. But before using it, it is well to expose it in a large tub to the atmosphere for a few days, adding water when it is used. It is greatly helped if either a peck of snot or a couple of pounds of gunny or other artificial manure, put into a coarse bag, be soaked in the liquid. As to what vegetable slops can be used for, there are really none in a growing state that may not be benefited

by it. If the artificial manure be added, then let the diluted water be six to one of the other. The exposure softens the liquid. Great quantities of such valuable plant-food are wasted, which, if put into a large tub stood in an out-of-the-way place in a garden, would prove most valuable manure.]

Growing Celery with artificial manure.—Temler, well-blanching Celery is highly appreciated by most people, and not a few amateurs would embark in its culture that have never done so could they see their way to obtain material to grow it in. In many instances it is very difficult to obtain solid manure, and in others the garden is so placed that it is difficult to get manure to it. These people are under the impression that Celery cannot be grown without solid manure. This is a mistake, and some two years ago I put the matter to a test by planting 50 plants early in July in some soil in good condition after Potatoes had been dug. These were good strong plants, and were lifted from the nursery bed with a ball of soil. No trench was made for them; they were simply planted on the surface, giving them a good watering, and keeping them moist in dry weather. When growth had advanced somewhat I gave the soil all round them a good sprinkling of artificial manure, watering it in. It was astonishing how quickly the roots came to the surface, and growth was rapid. This was done twice. Early in November these had the first bit of soil drawn to them, and in about a month finally earthed up. In this way I had splendid Celery after Christmas.—J. CROOK.

Late planting of early Potatoes for seed.—For many years I have striven to prevent my early kinds of Potatoes from making sprouts till after Christmas, but with very poor results in some kinds, notably Sharpe's Victor and some of the early American kinds. It is strange how some kinds start into growth so quickly compared to others, and it seems well nigh impossible to keep them at rest. I used to select my seed tubers from the main crop when lifting for eating during the last half of July and early in August, spreading them out to green, and then keeping them exposed as long as I could in autumn. Frequently they had started to grow in October; thus it sometimes became necessary to rub off the shoots twice or more. Last year I resolved not to keep any seed tubers from the main crop, but to hold back all the smallest at planting time, and plant these especially for seed. This I did, planting them from the 1st to the 21st of June, according as crops came off to admit of this being done. Needing them only for seed, I planted them 18 inches apart in the rows. The ground being warm, the growth was rapid. I allowed these to remain in the ground till early in November before I lifted them, and was astonished to see the nice crop from so late planting and such small seed. These were stored out of doors, covering to keep dry and from frost, and removing them to the shelves. I generally put them in early in January in this way not even Sharpe's Victor had wanted the sprouts removed. -- J. CROOK.

GARDEN WORK.

Conservatory.—The real gardener has very little leisure. His thoughts must, without ignoring the present, range a long way into the future. At the present time he is thinking about placing his Tree-Carnations and Chrysanthemums in their flowering-pots. As regards the latter, where many plants are grown, it is a work taking up much time, and slipshod work will not do. The soil must be of the best possible character and must be rammed firmly in the pots. The pots must be clean and the drainage ample in quantity and well arranged in the pots. Turfy loam, rather inclined to adhesiveness, the Grass fibres dead but not decayed altogether, will form two-thirds of the bulk, the remainder will be composed of old leaf-mould, a little two-year-old cow-manure if obtainable, a sprinkling of soot, some sand, and about one pound per bushel of some artificial manure which I need not particularise, as several things are available and equally suitable. After potting, the plants must stand in an open situation either on boards, tiles, or a good foundation of ashes, and be securely staked, the tops of the stakes to be fastened to wires strained to stout poles firmly driven into the ground. The watering must be in very careful hands, as if over-done at the beginning the soil will be soured and failure will ensue. In watering newly potted plants the greatest possible care must be exercised not only with Chrysanthemums but all other plants. It is better even to let the foliage wilt a little than over-water, though when the wilting process begins no time should be lost in giving the plants a drink, because we are on dangerous ground. On fine days use the syringe freely twice a day. This is a great help to plants which are busy making roots. There is very often a scarcity of flowers suitable for cutting just now. Of course, there will be plenty of Roses and Trumpet Lilies, and the later buds of the Lilies will open in water. According to our present ideas, Pelargoniums are of no use for cutting and Spiræas are not very lasting. There is plenty of white and yellow Marguerites and Carnations, and outside double white Narcissis and the large form of single Pheasant-eye Narcissis are abundant. Genistas should be pruned into shape after flowering and repotted as soon as growth begins.

The warm-pit.—A well-heated low pit, either lean-to or span-roofed, is just the place we all desire at this season for growing on stove stuff, and for bringing on Geineras and other things which require heat, moisture, and shade. Young Crotons, Gardenias, and Dracænas may grow sturdily near the glass. Here too, also, one may generally find a back wall or some other spot for planting out Euphorbia jacquiniiflora for producing long sprays for cutting in winter. This Euphorbia is very often a weedy thing, but plant it out in a warm house where the sunshine can reach it later on to ripen the growth, and one can cut and come again, or if the flowering sprays are left, the wall becomes a blaze of scarlet during the winter. The low warm-pit is just the place for pushing on a few pots of Eucharis Lilies if wanted in a hurry, or to push on a specimen Ixora or any other choice plant or Orchid which may be required at any particular season. In these low places we can easily fix a shade over a plant in bloom without shading the whole house, and when the days are warmer and the plants are transferred to a cooler place we can fill up with something useful, such as Cucumbers, Tomatoes, or late Melons. Night temperature now 61 degs. to 70 degs., air to be given at 80 degs. to 85 degs.

Cucumbers in bearing.—Give frequent top-dressings of good loam mixed with a little manure. When planted in light soil Cucumbers make rapid growth, but they soon run themselves out. If Cucumbers are wanted to last through the season, plant in loam of rather heavy texture. They will make less growth, but it will be firm and strong and there will be less labour in stopping and other routine work. Nourishment, if required, can be given in the shape of liquid-manure. A cool greenhouse will grow Cucumbers now if kept close and warm by shutting up the sunshade in the

and using moisture freely on floors, etc. Always keep a few young plants of both Melons and Cucumbers in stock.

Watering inside Vine borders.—If inside borders are well-drained and made up on a foundation of rubble, it is scarcely possible to overwater just now. Many inside borders do not get enough water, and the Vines suffer in consequence until the roots can find an outlet somewhere, and after that the result depends upon what kind of a feeding-ground the roots reach. On the majority of soils the best way is to keep the roots at home by giving rich top-dressings at suitable seasons. These top-dressings are usually given early in spring, and if the roots take possession of the new stuff, which they will do if kept at home, additions in some concentrated form can be made. Keep the sub-laterals in thorough check by frequent attention. Fires must be kept going as long as necessary, but bank the fires up early on bright mornings. Night temperature now 60 degs. to 65 degs. Give a crack of air early in the morning, and add it as the sun warms the atmosphere inside the house. Close early in the afternoon. Sometimes we have very warm nights, and then a little night air will be beneficial.

Window gardening.—Repot Ferns, Palms, and Aspidistras in good loam, peat, leaf-mould, and sand, the last to be used rather freely if the loam is heavy. Pelargoniums are now in flower and must be well supplied with water. Pot off cuttings of Campanulas and Fuchsias as soon as well rooted. Pinch out the points of the shoots to make them bushy as soon as the roots have got fairly into work after repotting. Use the sponge freely over fine-foliaged plants. A small sponge, dipped in soapy water, will remove insects from the foliage.

Outdoor garden.—There is more than one way of improving a weedy lawn. I have seen men and boys at work between lines which enclose a narrow space digging out the weeds. This is a long, tedious, and generally an expensive business, and both weeders and wage-payers are generally weary of it before the job is finished. No doubt if it is persevered with it is effectual, but when the weeding is finished a rich top-dressing should be given. For several years past I have been noting the effect of lawn sand upon weedy turf. It certainly kills the weeds, and in the long run improves the turf, though it may give the lawn a dark, rusty appearance for a time. The sand is not expensive. Anyone can try it experimentally at first by buying a shilling tin or so. This is the best time for top-dressing rock gardens and ferneries. It is best to use a little good compost, such as loam, leaf-mould, and sand, with a little peat for certain things. This annual top-dressing is a great refresher to the plants. At the same time those which are likely to encroach upon a weakly neighbour can be reduced. The grouping system is the best to adopt, and then there will be fewer things crowded out. Thin hardy annuals freely as soon as large enough. The soil in the Dahlia-beds should be in good condition, though fresh manure should not be dug in now—better keep it for mulching later on. This is the best season to plant out Clematises from pots against walls or fences. The Jackmanii section will do very well for arches, or to form a mass anywhere. Clematis Flammula is a sweet thing anywhere.

Fruit garden.—Mulch Raspberries with good manure. Keep the moisture in the ground, the plants will want it before the crops ripen. The Codlin-moth is present in many, I might say most, orchards and gardens. Fruit growers are becoming alive to the necessity of dealing with this pest. This is the season for spraying the arsenic and lime mixture over the trees. There are other things that are effective but not so cheap. One seems to have a repugnance to the use of arsenic in such a wholesale way in gardens, but it is used largely in America. There are petroleum washes that will effect the object if arsenic is objected to. It is necessary to be prompt and persistent. The American blight seems to be spreading. This also calls for energetic treatment all through the summer. A bottle of paraffin-oil and a small brush should be kept ready for use, and all the white spots touched up with the brush as they appear. Of course,

large trees can hardly be managed in this way, and the best way to deal with large old trees is to grub them up and trim them or cut off the tops and re-graft after thoroughly cleansing the old stems. There is a wonderful bloom on the Apple-trees in this district, and if all the blossoms set the trees must be well supported with rich top-dressing and liquid-manure. There is too much cropping, and other things, over the roots of fruit-trees. Discontinue this and keep the spade from the roots and the trees will pay for it. There is still money in fruit growing if rightly managed.

Vegetable garden.—A good deal of attention must be given to thinning and hoeing among young crops now. Where unprotected the frost has blackened the tops of early Potatoes and stopped progress for a time. Weeds may be blessings in disguise, but they give a lot of trouble, but the weather though cold has been dry and favours the man who uses the hoe or fork, and both tools should be in requisition now. The frost has cut off a good deal of the early Asparagus. It is a serious loss to many market growers, and there is no help for it. Then plantations of Globe Artichokes may still be made, as the growth is backward. This plant wants a deep, rich soil, and plenty of room. Windsor Beans may be planted for a late crop. If the dolphin-fly appears on the early Longpods, nip off the tops and remove the colonies of insects. They seldom attack a second time. Cauliflowers under handlights will soon be turning in, and should have a leaf broken over the heart. Liquid-manure will be helpful. There is yet time to sow the long-rooted Beets, as very large roots are not wanted. Make a further sowing of Horn Carrots; they are always appreciated when young. When the early Potatoes are cleared out of frames rearrange the beds and fill with Cucumbers, Melons, Tomatoes, or something useful. Keep up a supply of salad plants by frequent small sowings.

E. HODAR.

THE COMING WEEK'S WORK

Extracts from a Garden Diary.

May 19th.—Sowed Hollyhocks in drills in the open ground. We have followed this course for some years, and found the plants healthier and stronger than when we sowed under glass. This, after all, is only reverting to our old practice before we got into the habit of trying to rush things. Sowed *Dieltamnis Fraxinella* in box in frame. There is some advantage in this. We find the seeds grow better. The same may be said in sowing seeds of *Scabiosa caucasica*. Pricked out more Celery. Sowed a few lettuce seeds of White Cos and Continuity Cabbage.

May 20th.—Mulched early Peas on south border. It is a dry, hot spot. Sowed Chinese Primulas and Cinevarias, including a few seeds of *Cineraria stellata*, useful for cutting and conservatory work. Arum Lilies which have finished flowering have been placed in a sheltered place outside. Some of the later plants are still blooming, and will be kept inside for a time. We are treating the flies on Peach-wall to Tobacco-powder.

May 21st.—Planted out first lot of Brussels Sprouts and a couple of rows of White Celery to come in early. Shifted on Acacias and Genistas which required more pot room. Pricked off a lot of *Primula obconica* seedlings. We find this useful in winter, in spite of its bad character, and should not like to be without it. Dusted a little Tobacco-powder on the centres of Trumpet Lilies just coming up to flower. The powder is very effectual. A very small quantity suffices.

May 22nd.—We have just made a start with the bedding-out. We have much to do, and the plants are well hardened. Tender things will be kept back till next month. Blossoms have been picked off Strawberries planted to produce runners. Shifted on a lot of winter-flowering Begonias, Gloire de Lorraine and others. Thinned Apricots and Peaches on walls as the crop is too heavy. Grape thinning is still going on in late houses.

May 23rd.—Shifted on young Fuchsias, chiefly new varieties. Planted several frames with Cucumbers and Melons. Tomatoes for planting out are still in cold-frames with lights off during warm days. Will soon be planted out if the weather settles. Planted

out a collection of Cactus Dahlias, chiefly new varieties. Top-dressed Cucumbers. Chrysanthemums are still in cold pits, but the lights are taken off every day. Pinched off the tops of Longpod Beans.

May 24th.—Earthen up early Potatoes. Prepared shallow trenches for Leeks. Made a further sowing of Marrow Peas. Peas coming on are staked in good time so that the tendrils have something to cling to. Sowed Cardoon seeds in trenches 15 inches apart. Tied down young wood in Peach-house. Gave inside Vine borders liquid-manure. Sprinkled a little bicarbonate of soda on Onion-beds.

TREES AND SHRUBS.

THE MEXICAN ORANGE FLOWER (CHOISYA TERNATA).

We are reminded of this beautiful shrub, a correspondent having just sent some flowers

TREATMENT OF WISTARIA.

I HAVE a Wistaria growing on the south wall of a church. It has grown in about two years to a height of 25 feet. As it grows in height it loses its lower foliage, and the stem for nearly 7 feet is quite bare. Will you please advise me (1) how to prevent this loss of foliage? (2) How to make the creeper shoot at the side without cutting it down? (3) How the side shoots it has can be made to spread (most of them end in bushy pieces with no leaders)? (4) How soon may it be expected to flower?—H. G. BABINGTON.

[The Wistaria behaves naturally as yours has done, unless measures are taken quite early to check it. In commencing with a young plant the top should be cut off if there are not a couple of good side-shoots. These last should be trained in a horizontal manner, one on either side of the main stem, and as the plant grows another couple should be carried out in a similar manner a yard or so above the first ones. In this way you may continue to lay the foundation of your plant till the space is to a great extent furnished. An established plant against a wall will well repay a little attention in the

will go together. As your plant is young and flexible, you might bend it down and secure in position, and the sap being then arrested side-shoots will follow. The loss of foliage can only be prevented by the formation of side-shoots carrying leaves of their own. 3. The side-shoots can be made to spread if the leading shoot is stopped, and the bushy pieces at the end are cut away except the most vigorous one, which will then grow freely. 4. A plant of the size you name should flower this spring, but as it has grown so vigorously you may have to wait another year.]

PLANTS AND FLOWERS.

INDOOR PLANTS.

POTTING AZALEAS AND CAMELLIAS.

IN looking through several amateurs' gardens lately I was reminded that Azaleas and Camellias are, as a rule, in very poor condition in such places, at least those that have been any length of time on the premises. The healthy little plants brought from the nursery, if left undisturbed at the roots, usually flower fairly well for two or three seasons, but as soon as they require repotting they begin to decline in health, and in very rare cases does one find the plants really flourishing.

Azaleas and Camellias require ample drainage—this is the first consideration in repotting. Take clean pots, also clean potsherds, place the largest at the bottom, and medium-sized ones next, over this a layer of smaller ones. For Azaleas only the best fibrous peat is of any use, and for Camellias the same material, and some rich, fibrous turf, that has been packed up just long enough to kill the Grass; pull this to pieces, but do not sift it, place the roughest soil over the crocks, and then transfer the plant to its fresh pot. Large shifts at one time are not advisable; young plants in 5-inch pots may be placed in 6-inch or 7-inch ones, which will allow of a nice layer of fresh soil being placed all round the ball of earth, but before doing this the old ball of earth should be divested of any inert soil, and the roots carefully loosened when they are very firmly matted. The new soil must be very firmly rammed down with a blunt stick or lath, so that the new soil is made as firm as the old ball of earth itself. Allow about half an inch at the top for water, and as soon as potted and set in position for growing give a good soaking of water from a fine-roseted pot to thoroughly saturate the entire mass of soil. The plants should be shaded from bright sunshine, and syringed overhead as soon as the sun declines, and be shut up with a brisk, moist heat. Do not over-water at the roots, but never let the soil get quite dry. Under favourable conditions, both Azaleas and Camellias will make rapid growth, and as soon as the young shoots get firm, flower-buds for the ensuing year will be formed, and as soon as these begin to plump up the plants must be gradually hardened off by admitting plenty of air, and in July they may be placed out-of-doors to ripen their growth. A cool, moist bed of coal-ashes behind a wall to screen the plants from midday sun is the best of positions for them, daily attention as to watering being all they will require until the first week in October, when the pots should be washed and the plants set in their winter quarters, which should be cool, light, and thoroughly ventilated. Camellias will flower naturally from Christmas onwards, but Azaleas require more heat to cause them to bloom in the winter months, but by judicious hastening of early-flowering varieties, and retarding late ones, a succession of bloom may be kept up for nearly half the year. F.

NOTES AND REPLIES.

Malmeson Carnations.—I am anxious to know what treatment I can give some Malmeson Carnations I purchased from a good and well-known nursery last year? The stems look dry, but they appear to have some nice shoots at the top. They did not flower well last year. Ought they to be repotted?—C. A. S. M.

[We are quite in the dark as concerns your plants, and you give no idea of their present condition, the soil, or any other particulars. If you purchased young plants a year ago,

The Mexican Orange Flower (Choisya ternata) in a Devonshire garden.

for name. The illustration we give to-day shows it growing in a Devonshire garden—a county that contains many beautiful specimens of plants that in more northern districts are only known as greenhouse plants. Those who are fortunate enough in having a bush near the house must know the pleasure of an atmosphere laden with the strong but not too powerful Hawthorn-like fragrance. Those who intend to try this shrub in the open should bear in mind that the best results are always obtained from planting in a light, sunny position, where the wood can be well ripened before the winter begins. Plants, the wood of which has been well ripened, are never so likely to suffer as those in a green and ill-ripened condition. It is a very old plant in gardens, having been introduced from Mexico about 1824, where it grows freely on the hillsides, presenting a delightful picture during the flowering season.

matter of pruning and training. In the early part of the month of July all shoots that may be reserved on the main or leading stems should be cut back to within a foot of the main stem in order to check the rampant growth. These shoots will again break into growth from the buds just behind where the shoot was stopped, and after these shoots have grown a few inches they may again be stopped. The result will be the formation of flower-spurs at the foot of the shoot first shortened. Early in the following spring these shoots should be cut back to within five or six eyes of the main branch from which they originate, and the young growths from these eyes are then to be treated in the same way as those of the previous year. When the leading shoots have reached the length it is intended they should attain they may be stopped, and the result will be a neat appearance without any stiffness or formality. With regard to your numbered queries, Nos. 1 and 2

these, with proper care, should be now showing the flower spikes, yet it would appear you have no such sign. Here are some particulars of the general treatment of the Malmaison Carnation, but it is difficult to say if such will suit your case. Young plants, whether cuttings or layers, should now be established in 4-inch pots, and ready for a shift to 5-inch or 6-inch pots. In the latter they should flower the following year. Strong layers of last year potted early in autumn should now be in spike or blossom, according to treatment. The soil should be a free, open, or sandy loam, with which one-sixth of finely pulverised and old cow-manure may be mixed, with the addition of charcoal, or, failing this, old mortar-rubbish. Perfect drainage and firm potting are essential. We cannot say if the plants require potting or not, as you say nothing of their size or the pots they are now in. A woody condition at base is quite natural with year-old plants. If your plants show no sign of flowering shortly, the better way will be to layer the best shoots early in July. These by the end of September should be rooted sufficiently for potting, and good, well-rooted layers, if well cared for, will flower in the cool greenhouse next spring.]

Azaleas and greenhouse.—I am thinking of building a span-roofed greenhouse about 20 feet by 10 feet against a brick wall 5 feet high, facing east. I suppose the house should be about 8 feet high at the ridge—or would 10 feet be better? If so, I must add 2 feet either of brick-work or glass on the top of the wall. Which of these would you advise? My object is to grow (or, at any rate, to preserve) Azaleas. Any other plants must be subordinate to these, but I should like to have *Oleanders*, *Clematis indivisa*, *Heliotropes*, and, perhaps, *Fuchsias* (one end will be partly shaded by a Walnut tree). I suppose I need not use more heat than will keep the frost out in winter? Will you tell me whether the following plants already growing on the proposed site will continue to thrive if the house is built over them, or should they (for their own sakes) be removed? On the wall: *Pyrus japonica*, *Roses Gloire de Dijon*, *Marie Henriette*, and *Bardon Job*. In the border: *Plum Victoria* and *Green Gage*, *Pyrus Malus floribunda*. I suppose a *Marchal Niel* would do well in such a house?—C. E. S.

The Azaleas being the most important crop, and not specially dependent on sunlight while under glass, we think the 8 feet high ridge will do quite well. If such an angle would give a rather flat roof, this may be modified by keeping the eaves 3 inches under the top of the 5-foot wall, thus giving a sharper rise on roof. In any case you need not raise the wall in the least. What is most usual when erecting glasshouses against a wall is the three-quarter span or hip-roof, and this may have a 6-foot length of rafter to the wall from ridge, and a 12-foot long rafter on the other side, or any proportion that may suit. The chief object of the three-quarter span—the name being derived from the two quarters on the long side and the one quarter on the short side—is the gaining the full sunlight with the proper utilisation of the wall. The objections to the style in such a case as the present are the low roof on the long side and the doorway, which would not be quite central. It will be quite as useful, however, if you erect a full span, taking your gutter level at the wall side at 4 feet 9 inches high. We suggest this for solidity, and by knocking out a brick here and there and inserting a "healer" half way into the wall you will obtain a perfect bearing on that side. On the front side 3 feet of wall, and the remainder wood and glass to 4 feet 9 inches. The plants you name will be easily accommodated, and the *Clematis indivisa* will be best planted out at one end and trained up the rafters. The temperature in winter need not exceed 45 degs., or 40 degs. in severe weather. It will hardly be prudent merely to keep out the frost, and in this one may be caught napping. The plants now growing in the border and trained to the wall should be removed; the *Roses* you mention would only become wild and unsatisfactory, and are much better in the open. A *Marchal Niel* Rose will do quite well, however, and if you require any more we suggest *Niphetos*, *Briar* or *Bridesmaid*. All these are free, and beautiful in the bud.]

Keeping conservatory moist.—Will you kindly tell me how I can obtain a damp atmosphere in my conservatory? It is always too dry, which I know is not the best for plants. It is not intended to be other than a cold-house or all kinds of easily kept flowers and creepers. The conservatory faces S.W., and leads out of the drawing-room by sliding doors, and measures 21 feet by 12 feet, so it is a fair tank runs the whole breadth at the end, and a rain-water tank over it, except where the opening is to get out water. When this is left open no moisture is given out. How water pipes (only used in hot months) run under the conservatory, the whole site

floor is paved with tany tiles. I find that the small greenhouses which several of my friends possess always have such a damp heat, even those which have no heating apparatus or only a small oil-stove for severe weather in winter. But I notice they all have earth floors, often watered, and also earth underneath the side staging, where Ferns, etc., grow. Is this the secret of the dampness? Would it be possible for me to have an earth floor with wooden staging over it to walk on, or would this create dampness in the drawing-room?—A. D.

[Your conservatory furnishes another illustration of the fact that the ideas of the builder and the plant grower are greatly at variance, for the earthen floor is, from a cultivator's point of view, much the best, and the glazed tiles the very worst. Again, there is the drawing-room to take into consideration, as too much moisture close by night not be desirable there. You do not say what kind of staging you have, but if it is of open laths a good deal might be done to combat the dryness complained about by laying some slates thereon, and covering with 1 inch or more of fine Derbyshire spar, or what is now being greatly used by many successful cultivators, small coke broken to about the size of Horse Beans. This coke is a great absorbent of water, and even when charged with moisture it is always sweet. Again, in a case on which our advice was previously sought, considerable benefit has been derived from the treatment of the space under the front staging, which was, as in your conservatory, also tiled. To avoid too extensive an alteration the space underneath was covered with about 3 inches of fairly small coke, of the most absorbent quality it was possible to get. This, which lay on the tiles, was kept within bounds by a neat edging, and was by no means an eyesore, especially when two or three Ferns and a piece or two of *Selaginella* cropped up to take off the raw appearance. Of course, what is technically known as damping down (that is, frequently watering the coke with a rose-pot) is carried out, and as above stated the results have been satisfactory. It would be quite possible to have an earthen floor with wooden staging to walk on—indeed, this may often be seen—while for paths some prefer what is known as stable bricks, that are so grooved as to allow of walking dry shod even when water has been thrown on the floors. If you follow the above suggestions and damp down regularly we do not think you will find it necessary to remove the tiles.]

ROSES.

SEASONABLE NOTES.

PERHAPS of all the months of the year this is the most important to the Rose grower. A word of caution is necessary as to

MANURING ROSES.—There are so many compositions on the market, and they all promise wonders, that the novice is apt to use them with too free a hand. For my part, I have never found any manure yet that will surpass in effectiveness and safety good farmyard-dung. This would consist of manure from various animals—pig, cow, horse, etc., with poultry-manure added. Let anyone visit a small village where the leading farmer is a Rose enthusiast, and he will find in his garden blossoms of the greatest perfection, rivalling many that are seen at our shows, excepting, of course, those grown by the experts. I will assume that the *Roses* have received their autumnal dressing of farmyard-manure, and that this was covered over or lightly forked in in March; if so, no further stimulant will be needed until the buds begin to swell, which will probably be about the beginning of June, unless hot weather appears pretty quickly. If at that time the plants are strong, they may receive two or three quarts each, once or twice a week (according to vigour, giving the strongest the most) of good liquid manure, the best being drainings from a farmyard, or, failing these, some good strong liquid mixed up in a large cask. A bushel each of cow and sheep-manure, with a peck each of wood-ashes and soot, put into a 50-gallon cask of water and allowed to stand four or five days before using, will provide the amateur with some good stimulant for his *Roses*. This liquor may be applied at half strength, and after the cask has been refilled about twice it may be given neat. It is a good plan to put some 8 lb. or 10 lb. of gypsum (sulphate of lime) into the manure tub. This will prevent any injurious effect

that might follow should the liquid be given too strong, and, moreover, it supplies a substance which is often wanting in soil. It is a difficult problem with some individuals how to obtain the materials for a tub of manure similar to those alluded to, and, of course, where this is so, artificial manure must be employed. There are some excellent stimulants among them if rightly used. Bone-dust is a capital fertiliser, and, if the plants did not have much manure in autumn, 5 ounces or 6 ounces per square yard may be given at once and hoed in. Fish guano and Chinchas guano are also good. About a teaspoonful once a fortnight will be beneficial, alternating it with liquid cow-manure, but withholding as soon as colour of flower-buds is seen. A very excellent liquid-manure may be made with 1 ounce of nitrate of potash and 1 ounce phosphate of potash to 1 gallon of water. This is readily dissolved and is very quick acting, and should be given when buds are swelling. Be very careful not to apply liquid-manures when the ground is dry. If rain does not come give a watering first with plain water.

THE NEW GROWTHS must be freely thinned if show *Roses* are wanted. A moderately-sized plant should not carry more than three or four blossoms, and six blooms are enough on any one plant. The garden *Roses* may be allowed to grow as they like until the end of the month, then the overcrowded shoots are best removed; for even in such *Roses* where we wish for a profusion we also prefer to see good quality rather than the reverse. It is surprising what an added beauty there is in a garden *Rose* well grown. Take, for instance, the puny flowers of a half-starved plant of *Camoenis*, or *Marquise de Salisbury*, and the beautiful, brilliant, and bright blossoms of the same varieties well cared for.

SUCKERS from *Brier*, *Manetti*, *De la Giffemie*, or *Polyantha* stocks must be removed as fast as they appear. It is oftentimes puzzling to the amateur to know which is a wild sucker, and if he is in doubt I would advise him to wait. I have known fine promising growths of the *Rose* itself cut away under the impression they were suckers.

STOCKS BUDDED last summer should be looked over frequently to remove suckers, and also to tie to a support the fast-growing shoot. Our dwarf buds are kept earthed-up until the last moment, and even when the supporting stick is placed against the stock the earth is replaced about the base of the bud. This is very necessary in low-lying districts where such havoc is wrought by May frosts. If bushy plants are needed for potting up, we pinch out the point of the young shoot when it has made its third and fourth leaf, but if fine early blooms are required for exhibition then this must not be done.

THE AERATION OF THE SOIL is of the utmost importance, and I cannot too strongly urge on the amateur the frequent hoeing among his plants, both huddled and established. The first hoeing should be of a deep nature, then after this the work is easy, it taken in hand before weeds gain the ascendancy. On a hot bright day a push hoe or Dutch hoe will enable the *Rose* grower to get over a lot of ground, and not a weed will be seen an hour or two afterwards. But let the weeds grow to a large size and it will take all the summer to clean the land. Although hoeing is employed to clean the land of weeds, its primary object should be to air the soil. This is one reason why I discourage the planting of various low-growing subjects on the surface of the *Rose* beds, as undoubtedly it must hinder the proper cultivation of the latter. Always hoe after rain or watering, and do not walk upon the soil any more than is absolutely necessary. Some

PILLAR *ROSES* that we have allowed to go free for want of time to tie up are among the most healthy-looking objects we have, and suggest by their appearance that too much bunching up is practised with this style of growing the vigorous kinds. With large old plants try the use of three stakes instead of the central one, so that the overcrowding is avoided. Perfect pyramidal pillars may be so formed. The

WINDMILLIANA HYBRIDS upon old tree stumps are now a very pleasing feature, and this is

certainly the best way to grow them. One is able then to clean the ground beneath. How beautiful Jersey Beauty looks just now, with its hundreds of little red growths, every one like that of a Tea Rose, but quite hardy. One of last year's novelties, Alberic Barbier, has even more lovely shaly foliage than that of Jersey Beauty.

OLD-ESTABLISHED CLIMBING ROSES may be effectively helped by the making of a few holes about their base with a thick crowbar, and then giving them some liquid-manure. A good liberal supply should be afforded in frequent instalments during the day, as it naturally will not pass away very quickly. Rosa.

NOTES AND REPLIES.

Some good new Roses.—Those fortunate Rose growers who are able to purchase the best of the new Roses as they appear should be on the alert, as last year was a very good one for novelties. I would strongly advise that the following be secured now and planted out at the end of the month. They will give some good buds by July. The varieties are: Fran Karl Druschki, Mme. E. Levayasseur, Mme. Viger, Souvenir de Jean Ketten, Soleil d'Or, Boudicca, Noella Nabonnand a grand climber, as rampant as Reine Marie Henriette, with colour of Bartou Job), Mme. Antoine Mari, Mme. Vermorel, Lady Morgan, Beauclerc, Mildred Grant, Lady Battersea, Lady Clamorris, and Duchess of Portland. These I consider the best of last year's novelties.—Rosa.

Roses under glass are now swelling, and will need a deal of assistance. Manure made with cow-dung and soot affords a safe fertilizer. If the plants are rather dry, give a watering first with plain water, then some of the liquid-manure. About once a week until buds show colour will be the correct thing. I have found, too, a most excellent stimulant and a safe one in the following: 1/2 ounce each of salt-petre and phosphate of potash to 1 gallon of water. When dissolved, apply as ordinary liquid-manure and about once a week. In a greenhouse in which heat and moisture can be given during summer some of the fine climbing Roses should now be planted, such as Fortune's Yellow, Climbing Niphotos, Marchal Niel, the old but seldom seen Cloth of Gold, Teshunt Hybrid (a beautiful bud under glass), and Mons. Desir. Where a wall or pillar some 5 feet or 6 feet in height needs a Rose, plant Mme. Lambert, Mme. Hoste, Kaiserin Augusta Victoria, Perle des Jardins, Sunrise, Niphotos, Souvenir d'un Ami, Catherine Mermet, Bridesmaid, Anna Ollivier, or other similar good sorts. Young plants grafted this season will be the best to procure.—E.

Rose enemies.—Insect pests are now troublesome—there are so many of them. I wish there was some other method of destroying them than by hand-picking. Some of the tiniest little black grubs quickly wreck a fine shoot by mutilating the bud. As soon as a curled leaf is seen or two or three leaves glued together, make a search for the grub, and when found destroy it. Usually the culprit is found, not in the curled leaf, but in one up higher nearer the bud which is his goal. One kind of caterpillar has a way of dropping quickly to the ground, and there it will stay

until danger of capture is past. A bad pest is the one that bores its way down the pith of standard Briars and also of the hard wood of Roses. The Briars and the ends of hard wood should be painted over when cut back, using some ordinary paint or knotting. Aphides or green-fly may be checked considerably if they are destroyed as soon as one or two are visible. We are apt to think one or two can do no harm, but let them remain and they are grandparents in a few hours. I have often thought that a small fortune awaits the inventor of a ready means of destroying these insects outdoors. The aphid brushes are most useful, and will keep the pest in check if frequently used. They are more effective than the various washes, because the latter, unless the shoots are dipped in the liquor, always permit some to escape. Let the Rose grower observe which growths are most the prey of insect pests, and he will find them to be the old,

with plain water and liquid-manure. A mulch in summer shuts out the sun's rays and air. I have seen Roses almost ruined by a thick mulch applied in spring and allowed to remain on the surface. Rather should the hoe be frequently employed to keep a nice tilth. Always hoe after rain or watering.—B.

OUTDOOR PLANTS.

A SUMMER BORDER.

In the accompanying illustration we are shown a representation of one of those wide, wall-backed herbaceous borders, whose merits have been so often extolled in these columns, and on the planting and arrangement of which so much useful information has been afforded to amateurs. In the picture before us we may note that the advice so often given, that there should be an exact graduation of heights from the back of the border to the front, but that here and there taller subjects should be brought forward amongst dwarfier plants in order to prevent a too formal outline, has been followed with good results. The large group of giant Daisy-flowers coming well towards the front stands out clearly against the Iris foliage behind, and is flanked on one side by Sea Hollies, and on the other by Tiger Lilies not yet in bloom, close to which may be described a few spikes of Madonna Lilies in full flower. In the background, to the extreme left of the picture, is a clump of Delphiniums with massive, closely-set flower-heads, behind which three tall Hollyhocks tower, the unexpanded buds terminating their blossom-spikes showing a good foot clear of the coping of the wall.

A summer border.

In the distance is another large clump of Delphiniums fronted by Lychnis chalcedonic, while numerous plants of varied heights give the border an informal appearance. The dwarf Campanula that commences the edging in the forefront spreads well into the path, as do the majority of the plants employed for the margin of the border, and it is not until the eye reaches the closely-tufted Sea Pinks that one realises how straight and formal is the stone or tile edging. Where such an edging is used, spreading plants of lowly growth that will entirely hide the length of palpably artificial line should be placed immediately behind it, when it will soon be lost to sight. Rough stone of the country makes an excellent edging, and even when freshly fashioned it is informal in its contour, while its interstices and inequalities are admirably adapted to the needs of the numerous hardy and vigorous rock plants of which we now have such a selection to beautify the verges of our herbaceous borders. S. W. E.

* * RAISED ROCK GARDENS.

A FEW weeks since you published a very interesting communication on rock gardens, in which the writer very properly emphasised the desirability of having rock gardens sunk below the level of the surrounding ground. This is undoubtedly the best arrangement where it is practicable, because it ensures two things of vital importance—viz., the air is thoroughly excluded from the plant roots, and they are always kept rock moist. I often think when I see disused stone quarries what ideal places they might be made for a rock garden, yet

worn out ones; the young and healthy almost always are free until a certain time, when the pests have exhausted their early victims and then turn to the other growths on the plant. It is apparent, then, if we would have healthy plants free from insects, we must cut away the old wood pretty liberally in spring, and even now, where the young wood is coming on all right, some of the oldest shoots might well be removed. Two or three really healthy growths on each plant are enough, because each of these will give two or three new growths each. This is one reason when planting that I prefer to put the plants rather close together, so that old worn out wood may be freely dispensed with without a bed or border appearing to be too meagre in growths.—E.

Mulching with manure.—This at this time of year is a mistake, unless the soil be a light and sandy one. In such a case it is necessary, and also frequent waterings, alternating

how seldom are they so utilised? Of course, it does not lie in the power of everyone to have perfection in the arrangement of his rock-work; space may be limited, the effect of the view from some favourite window might be spoiled, or plants may have become so established that an entire alteration in the structure of a rockery might entail too great a loss in moving them, so that raised rockwork must always be more or less of a necessity for many if they are to have a rock garden at all. And, lest any should be discouraged at the thought that the most perfect forms of rock arrangement cannot be theirs, let me assure them that many of the very best plants succeed better on raised ground than where it is sunk below the surrounding level. As I write I look out of a window, and in the short space of 36 feet between me and the road I have arranged at about 6 feet distance a low bank or bed, not more than 4 inches above the ground level; then, interspersed with blocks of granite, the soil rises irregularly behind till at a distance of 24 feet it is about 4 feet high. Beyond this it slightly falls again to rise to a height of 5 feet where it abuts on the road. On the very top of this 4-foot mound, nesting between smaller granite blocks which are just visible above the soil, are some twenty clumps of *Saxifraga Burseriana*, *S. Burseriana major*, and *Draba brunifolia*, with a few patches of *Erinus alpinus*. What can be more lovely than masses of *Saxifraga Burseriana* in February and March, with its crimson buds, its large, pure white flowers, and its glaucous green foliage contrasting so well with the purple-red of the granite? For weeks it was a perfect picture, delighting the eye every time one looked out of the window; and then the bright green and yellow of the *Drabas* carry on the colour for another month. Below this top-most group come in the prostrate *Hypericum*s repens and reptans, which in late summer will be smothered with their large yellow blooms, and hanging over the face of a perpendicular rock is a great mass of *Androsace lanuginosa*, one of the very best, freest-blooming and earliest plants which can be placed on any rock garden. It is better than *A. sarmentosa*, because it does not dump off, and it remains in flower for months. This particular plant has often had from twenty to forty heads of bloom at one time. I find it a bad plan to cut off the old dead wood (it springs afresh from the crown every year) until the new growth has made considerable headway.

On another high part of this small rock garden are several clumps of *Edelweiss*, which likes an exposed position where it can get every hour of sunshine and where the wind can rapidly dry the moisture from their woolly petals. Below these, and running over a very gritty, flat space, is a large patch of *Androsace sarmentosa* and *Androsace Chumbyi*, which I now always protect with a handlight in winter, just to keep the moisture from their rosettes, and abundantly do they repay this little attention to their requirements. Just to show how accommodating some plants are to their surroundings, here are *Eriogonum marginatum* and *macrocarpum*, which seem to positively revel in their dry, elevated position, and which last autumn seemed anxious to show that their flowering capabilities were simply unlimited. As the bank slopes gently downward towards the window, a number of dwarf *Phloxes*, such as *Nelsoni* and *Vivid*, find a home, and the marbled leaves of *Cyclamen* nearly cover the ground. *Iris reticulata* finds its way through them in early spring, along with *Leucojum vernum*, *Narcissus cyclamineus*, *N. triandrus albus*, and *N. minimus*. A little hollow is carpeted with *Veronica repens*, *Aubrieta Leichtlini* hangs down steep rock faces, and *Arenaria balearica* creeps up every chink and spreads itself over the rock surfaces. In a little hollow behind the principal mound is a great clump of that most useful, accommodating, handsome plant *Megasea purpurea cordifolia*, and below it, and sheltered by it, a colony of *Cypripedium Calceolus* flourishes.

The bank which forms my background and which abuts on the road is crowned by masses of large British Ferns, of which *Polystichum aculeatum* is by far the best, because it keeps its fronds fresh and green right through the severest winter.

and shade to a bed of *Trilliums*, *Cypripedium spectabile*, and *C. pubescens*, which are quite at the bank foot and a little below the ground level. In their shade *Cardamine trifoliata* flourishes along with *Linnaea borealis*, while a little to the left *Oncoclea sensibilis* spreads out its graceful fronds. On the left of the path leading into this little rock garden is another irregularly raised mound, on which grow all my most sun-loving plants, such as *Edraianthus Pumilio* and *E. serpyllifolius*. Of the latter there are several patches, and nothing can be more beautiful than the mass of deep purple flowers entirely hiding the foliage. *Dianthus alpinus* and several other *Dianthus* flourish here, and quantities of the encrusted *Saxifragas*, *Antirrhinum Asarina*, etc.

Just one word about the paths in a rock garden. I have tried many kinds, but I find the best material is rough flagging stone just as it comes from the quarry with its irregular edges, so that there are numerous little spaces between the stones, which, filled with grit, make ideal places for *Linaria pallida*, *Thymus lanuginosus*, and *Thymus serpyllum coccineus* to spread about at their own discretion. Where the path is more in shade *Omphalodes verna* takes their place and *Symphytum tauricum* is useful for the same purpose. On a perfectly level patch of limestone soil a score or more clumps of *Gentiana acaulis* make a fine show, and this little bed is edged with self-sown *Cheiranthus alpinus*, which is very pretty, but inclined to become a weed. Many other things besides those mentioned are growing in this very small space, and all on considerably raised ground; but perhaps I have said enough to show that for anyone whose rock garden must be a raised one if he is to have a rockery at all there is a certainty of being able to grow successfully many of the very choicest alpine. Only, if I might venture to give the experience of many years of rather costly experiment, I should just like to add that far greater pleasure is obtained by growing these comparatively easy things, and growing them in masses, than in trying difficult, rare, expensive plants in ones and twos. Good drainage and plenty of coarse grit seem to me the two essentials of success.

R. LAYCOCK ROUTH.

Silfjord Ferris, Banbury.

RAISING PANSIES FROM SEED.

Will you kindly tell me when Pansy seed should be sown under glass or outside, and how the plants should be treated till they bloom outside and after blooming? Will they form a perennial border when once established?—*MIRUS*.

[Pansies may be raised from seed quite easily and sowings may be made outdoors from March till October with every prospect of success. If you commence operations at once, there is no reason why you should not do so, and if ordinary attention be paid to the raising of seedlings, they should bloom in August and possibly earlier. We should advise you to make a sowing of the Tufted Pansies, as these possess a more robust constitution, are also free-flowering, and what you specially desire, they are perennial in their growth. Sowing at this somewhat advanced period, you ought to make up a small bed of soil in a cool quarter of the garden. By this we do not mean that an absolutely sunless position for the seedling-bed should be selected, but that instead a situation where partial shade can be afforded. A little care should be observed in the preparation of the soil, as this will assist in the progress of the seedlings. If a quantity of loam and leaf-mould in equal parts can be procured and passed through a sieve with a $\frac{1}{2}$ -inch mesh, and a liberal amount of coarse sand or road-grit added, and the whole of these ingredients well mixed, ideal material for the seedling-bed will thus be prepared. It is just possible you may have a difficulty in obtaining loam and leaf-mould, in which case you had better substitute for them the best of your garden soil and Cocoa-nut-fibre refuse. Sow the seed thinly after the surface of the soil has been levelled and slightly cover with a portion of the soil previously mixed and reserved for this purpose. Should the weather be warm and the soil dry quickly, a thorough watering, using a fine-rosetted can for the purpose, should be given to the seedling-bed. Under normal conditions the seed should quickly germinate, and in a few

weeks the seedling plants should be ready for pricking out into other prepared beds. Better results usually follow when seedlings are planted in a nice light, gritty soil, and a distance of about 2 inches between each plant and a similar distance between the rows observed. Healthy and vigorous root-action is encouraged by keeping the plants cool, and for this reason an occasional copious application of clear water should be applied.

While the seedlings are growing the beds in which it is intended to finally plant them should be prepared in readiness for their reception. Deeply dig the quarters just referred to, incorporating at the time a liberal dressing of fairly well-rotted manure. Soil of a rich and lasting character is the all-important consideration at the time of preparing the beds and borders, as there is always the possibility of the plants remaining in the same position for two or three succeeding seasons. The Pansy, and the Tufted Pansies in particular, are somewhat gross-feeding plants, and in a comparatively short time will rob the soil of most of the plant food. When the young seedling plants have established themselves in their second quarters their advance will be most marked. It is astonishing how quickly they develop into sturdy little tufts, and when most of the intervening spaces between the plants are filled up with growth one may fairly assume them to be fit for removal to their permanent quarters.

Previous to their removal, break up and level the surface-soil of the beds and borders. To often the plants are unduly crowded, and for this reason they can never do themselves justice. Had you begun planting in the early summer, 12 inches between the plants would not have been too much space to allow each plant, but as the summer will have passed before your operations are completed, 9 inches between the plants, and also a similar distance between the rows, will be ample. Lift each plant with a trowel, so that as large a ball of soil as possible may adhere to the roots, and when placing each one in position in its flowering quarters see it is embedded to its collar. Press the soil firmly all round, and in the cool of the late afternoon or evening give the plants a thorough watering. Blossoms will quickly follow the final potting, and then you must see the old blooms are persistently removed. This will keep the plants on the move, and also maintain the display. Keep a look out for novelties of sterling worth, and label them for perpetuating. It is very possible you may obtain some first-class new sorts, more particularly if you acquire your seed from a good source. You will find it better to procure your seed from one who makes a speciality of the Pansy, and as there are a few firms who devote special care to the saving of reliable seed, you could not do better than apply to one or other of them. In the late autumn cut back the old and coarse growths, leaving the tufted growths of recent development in the crown of the plants to develop the wonderful tufts for which the Tufted Pansies are famous. Some of the less robust plants are benefited by a mulching of well-rotted manure after the cutting back. These seedling plants in the succeeding spring and early summer should be liberally covered with delightful blossoms.]

Tufted Pansies—hoeing between the plants.—Plants put out in late February and early March are now bearing their first crop of blossoms, and every endeavour should be made to keep them going. At this early period the use of the hoe, Dutch or otherwise, should be constant, the frequent stirring of the soil contributing to their subsequent success. One result of a systematic hoeing of the surface soil is seen in the vigorous growth which the plants thus treated invariably put forth, and if the practice be observed with more or less regularity once a week, the display which follows is all that one could well desire. At this season, of course, there is ample room between the plants and between the rows of plants, too, and advantage should be taken of the present period, as the intervening spaces will soon be filled up. All that is wanted is a good rain, but should dry weather continue the plants should be freely watered.—D.

NYMPHÆA ROBINSONI.

This is one of the most richly-coloured varieties of *Nymphaea*. We have, the colour being a deep crimson, somewhat lighter towards the edges of the petals, the substance of which is excellent. The stamens are of a rich orange

further notes will be given), to concentrate all the strength possible into the crown of the plant if flowers of the finest quality are expected.

The following varieties will give a good succession of flowers, and, with the exception of the variety Princess of Wales, which does not

for the winter, and very sparingly watered during that time; in early spring the supply should be increased, and as much sunlight and air as possible given during the growing and flowering period. *P. marginata*, which requires the same treatment, forms an excellent companion plant. J. Rose.

Ravlinson Road, Oxford.

NOTES AND REPLIES.

Christmas Roses.—My Christmas Roses on chalk soil, planted in a shady position and not moved for five or six years, promised to bloom well this season, but half the blossoms were misshapen or failed to develop. Should the plants be moved or divided?—S. E. A.

[On any chalk formation you will need make special preparation for these plants if they are to succeed. The time they have been planted is just long enough to have made them into splendid tufts in the ordinary way, and little or no division should be required. What is lacking, we take it, is a sufficient depth of top soil before the chalk is reached and a too excessive drainage of the moisture. The following is a remedy if it is not too expensive: Excavate in any rather shady position to a depth of nearly or quite 3 feet, removing and discarding all the chalk found. At the level given place a thick layer of spongy peat, any of the close peat soils will do for the purpose, and not less than 9 inches or 12 inches should be inserted and firmly trodden down. Over the peat put a layer of cow-manure, finally filling up the bed to within 2 inches of ordinary level with some loam well enriched with manure. The peat in the bottom will act as a sponge or reservoir for the water, which it also gives off quite freely when required. In any case, there is the one great essential secured, namely, a good depth of soil and a cool rooting medium. In this way you may succeed with Christmas Roses even on the chalk. It may be rather expensive work, but it is the only way of thoroughly enjoying these valuable winter flowers. You cannot now replant them with safety, and had best defer the work to the middle of September. Meanwhile, water and mulch your plants to keep them alive. You may certainly divide them in September when replanting them.]

Clearing a pond of scum.—I should feel much obliged if you could assist me by giving me a remedy by which I could get rid of the nasty green slimy growth which has, during the last fortnight, covered a pond in which

Nymphaea Robinsoni. From a photograph by G. A. Champion.

tint, thus contrasting well with the deep crimson. Fully developed blooms are quite 6 inches across, and it is also very free flowering. The leaves are of medium size, spotted and splashed with dark reddish-crimson.

VIOLET CULTIVATION.

From the middle of April to the first week in May is the most suitable time to make new plantations of Violets for supplying flowers from the month of September to the first mentioned date. Various methods are adopted, no doubt all good in their way, some taking their runners in the autumn and dibbling them into a frame or into cutting boxes, while other growers rely upon dividing their old plants after they have ceased to throw many flowers, choosing the side growths with rootlets attached, avoiding the central growths as too old to be of any service. I have always adopted the latter course and found it to succeed admirably. Before interfering with the plants that are standing in cold brick pits or frames, prepare the site for the reception of the offshoots. Doubtless a north border is the most suitable position when the soil is extra light or sandy, or where very hot, dry summers are experienced, as the Violet is so subject to red-spider unless a deal of labour can be spent on it. On our soil, a deep sandy loam, Violets revel in any position except due south. In heavy, cold soils, plenty of half-decayed leaf-soil and road-grit or wood-ashes should be dug in a good spit deep. This would have been better done in February, still, I have prepared the ground just a few days previous to planting, and the plants do just as well as if dug two months earlier. It is important that the little plants be made quite firm in their new quarters, and be given 10 inches or 12 inches of space each way for the double varieties, while, for the stronger-growing singles, 15 inches is none too much. Plant with a dibber, and, unless showery weather prevails at the time, the plants should be watered in and attended to in this respect until established. Even then, in very dry, hot summers, on some soils, it is absolutely necessary to give the plants heavy waterings once a week or so, or they fall a prey to red-spider, their greatest enemy; frequent hosing or syringing with clear soft-water will generally rid them of this if persevered in. As soon as the plants begin to push out runners they should be gone over every ten days, persistently removing every one that can be laid hold of with the finger and thumb, this being better than leaving them for a month or more and then using the knife to remove them. It should be the cultivator's aim, from the time the runners are first planted, until the plants are ready for removal to their winter quarters, to keep them

prove as hardy with no as could be wished, though this may not be general, will yield a good supply from the open ground if the winter is not too severe. California, Princess Beatrice, La France, a grand Violet, and should be grown extensively, are my favourite singles. In the doubles, Marie Louise, Mrs. J. J. Astor, and Conte de Brazza are hard to beat, the first-named often giving nice bunches early in the month of August, and under glass it will continue the supply well into this month. Mrs. Astor is quite a new colour among Violets and much admired, and Conte de Brazza is at all times useful when white flowers are in demand. J. M. B.

PRIMULA PUBESCENS ALBA.

This (*P. nivida* of the catalogues), shown in the accompanying illustration, is one of the best of the cold-frame Primulas. It is easily

Primula pubescens alba (syn. *P. nivida*) in a pot. From a photograph by Mr. J. Rose, Oxford.

cultivated in light loam, with a free admixture of coarse sand and limestone chippings. October is the best time for repotting, the lower part of the rhizome when the roots are dead being cut away, and the crown of the plant kept 1/2 inch above the surface. The plants should be placed in a frame facing north

Water Lilies have been planted? I may say the pond was, until last year, an old pit hole, nearly dry, and overgrown with weeds, etc. It has since been thoroughly cleaned out, puddled, and filled with water to the depth of about 5 feet, and Lilies planted in it. Water

lately it has always appeared beautifully clean, but suddenly this slimy green growth has appeared. I have cleaned it off the top of the water with a hay-rake, but each time it has reappeared in about twenty-four hours, nearly as bad, and seems to come up right from the bottom and float in masses on the top. Would fish or water fowl be of any use in getting rid of it?—G. D. H.

Daffodils in chalk.—I should be glad to know how to treat Daffodils on a chalk soil. After the first year they almost cease to bloom, although the foliage was not cut down early.—S. E. A.

[Lift your bulbs early in July each year, trench and heavily manure the soil, working in the manure quite a foot deep, and replant at once or within a month. All the poeticus kinds must be replanted at once. You remark that the foliage "was not cut down early." Why cut it down at all, and why not let it ripen off naturally? If you cut off this immature leafage—the very lungs of the plant—and before its work is finished, how can you expect flowering bulbs another year? It is, therefore, quite possible you are responsible for the sparsity of blossoms of which you complain.]

Green-flowered Daffodils.—When I went to my present house three years ago I found a lot of double Daffodils—the common kind—and I took them up and replanted them after the first year, as they all came green and were of no use for cutting, and did not look nice in the borders. They are no better—plenty of blossoms, but very green, just here and there a yellow one. Can you tell me the cause and a remedy? Is there any use leaving them?—B. E. H., Kirkwall, N. B.

[The subject of your letter is a much vexed question, and of considerable importance, particularly where these things are grown for a livelihood. So far as the cause of the trouble is concerned, we believe this to be entirely due to the cold atmospheric conditions, and probably to frost at the time of the appearing of the bud through the soil. The flower-bud before it passes the surface level of the soil in its upward tendency has been subjected to much warmer conditions. Moreover, it has received all the protection of the earth and the surrounding foliage also. Therefore, should the external conditions prove much colder than the conditions below ground, and should frost ensue, as is often the case, so that the plant is brought to a standstill, a great check results that is shown in the way indicated in your note. That it is more or less atmospheric is generally proved by bulbs of the same quality where grown under glass earlier in the year coming their usual shade of yellow. Your only chance of assisting them to better ways will be by lifting the bulbs in July, and replanting not less than 6 inches deep in mid-October. This may cause a somewhat later start to be made, and in this way the cold and the check may be escaped. Could you so protect them by a mulch of light litter or by boughs that the extreme cold is kept from them, the chances are it would favour a better flowering generally. Beyond this we fear there is little to be done, as the complaint is the same, north, south, east, and west.]

Sweet Peas—staking recently-planted seedlings.—It is now the universal practice to give the young plants which are raised in pots the support of small twiggy sticks. This attention is not really necessary till the plants are some 5 inches or 6 inches above the soil, by which time the tightly-clinging yet fragile tendrils are fast developing. The earliest batch of these plants here was staked while they were in pots and stamling in the frames hardening off, preparatory to planting outdoors. When planted out this batch of plants was growing freely. The second batch, however, was treated somewhat differently, being planted when they were slightly less than 5 inches high. These were staked at the time of planting. Insert the stakes in such a way that the individual plants each have the support of a small spriggy stick. By these means, too, the entanglement of the growths is avoided, each plant clinging to the stake specially inserted for its support. In this way also the subsequent growths are more easily distributed over the larger stakes to be inserted shortly.—A. R.

ROOM AND WINDOW.

SPRING DECORATION IN THE HOUSE.

The accompanying illustration admirably portrays a unique floral arrangement, and one with which we are not in the least familiar. We are all aware of the beauty and fine effect a bowl of Daffodils will make, and know full well how much its beauty is enhanced when the lovely greyish-green foliage is freely associated with the blossoms. In the figure here given we have something very uncommon and decidedly interesting. The vase may not be quite so showy in its arrangement, as is the

blossoms of the Sir Watkin Daffodil. Then the greenish-yellow catkins of the two subjects used, Hazel and Willow, combine to give an artistic finish to the whole.

The foregoing facts should act as an incentive to readers of GARDENING ILLUSTRATED to make more frequent use of subjects which are generally considered to be out of the ordinary range of gardening material. From the earliest spring our hedgerows teem with suitable material, and its frequent use would, in the different seasons, considerably assist in maintaining the supply of flowers from the limited gardens of many readers. Vases with sprays of the Almond have made charming decorations

An arrangement of spring flowers and catkins. From a photograph by G. A. Champion.

case when the blossoms of one kind and of one colour only are used. Its originality is worthy of commendation because it shows how many hardly subjects may be employed wherewith to make a pretty floral picture, and something quite out of the ordinary. Few people would ever think of utilising small sprays of the Hazel with their pretty catkins. This, and many other such sprays, have a value for decoration to which too few, unfortunately, in the past have given heed, and yet how pleasing is the picture they create and what a departure from the orthodox methods of arrangement. It will be observed that the arrangement here portrayed is confined to flowers of tones of yellow, and thus the effect is not in the least incongruous. The soft yellow of the Primrose associates well with the rich yellow of the

in the early spring, and now that so many delightful flowering trees and shrubs are coming into blossom, it may be as well to call attention to a few of the more striking examples for the purpose under notice. The beauty of the different varieties of the Berberis cannot well be too highly extolled. A single spray of any of the Berberis is a picture in itself. The Cherries, too, are pleasing, and who can fail to admire the beauty of the wild form when in full blossom? The handsome double forms of the cultivated sorts are extremely pleasing. The Horse Chestnut is always admired, and when its spikes of blossoms are cut with a good length of stalk, they make a bold and handsome display when lightly adjusted in large vases. A charming floral picture can be made of sprays of the flowering

Arab (Pyrus Malus floribunda). Of course, there are other pretty varieties, but this is undoubtedly one of the best. Everyone is familiar with the Lilacs, and they are generally regarded with the greatest favour. The heads of blossoms being somewhat top-heavy, they are too often packed tightly together in a vase of limited proportions. A vase of goodly size in which the trusses of flower are lightly disposed is very effective. There are many excellent sorts, and their shades of colour are distinct and varied. The Guehler Rose or Snowball Bush (Viburnum) is another popular flowering shrub. This is not by any means easy to adjust, but a spray of its large round clusters of white flowers makes a pretty decoration. This brief list may well close with a reference to the Bush Honey-suckle (Weigela) with its graceful drooping branches, freely flowered pieces of which make a pretty display. D. B. C.

ORCHIDS.

NOTES AND REPLIES.

Bletia hyacinthina.—I enclose you a photograph of an Orchid Bletia hyacinthina, a terrestrial one, native of China and Japan, grown by me in a cool greenhouse, the temperature of which fell several degrees below freezing point during the winter on several occasions. It is of easy culture. Its resting period is during the months when there is no sun heat available. In potting it I used leaf-mould and sand, and when it showed signs of growth I gave it a copious supply of water frequently. The flowers are of a beautiful rose-purple, the lip is white streaked with red in the centre, and spotted at the edges with deep crimson. It flowers during April.—R. THOMSON, High Bickington, N. Devon.

[The photograph sent, which was, unfortunately, not clear enough for reproduction, showed a plant with four bracts carrying seven spikes of bloom.—En.]

Cool-house Orchids.—These can take water almost every day at this season. Many of the plants need surface dressing because of the Sphagnum Moss dying. I am never satisfied with the Masdevallian or the Odontoglossums until I can obtain a good growth of Sphagnum upon the surface of the compost. All that are in an unsatisfactory condition in this respect should have the decayed material removed from the surface and be replaced. Tear up some good light, fibrous peat, and sift out of it the finer particles. Get some freshly-gathered Sphagnum, and cut it up into ½-inch lengths with a knife. Some clean potsherds broken up into suitable sizes should be at hand, and also broken charcoal, the last not to be used so freely as the potsherds; spread the Sphagnum over the peat, and over all the crocks and charcoal. The material must be put on carefully with a crock projecting here and a piece of charcoal there, both embedded in the surface-dressing material, which should be pressed in firmly in about equal parts. Any unsatisfactory specimen may be repotted, for even if this is not altogether the best time of the year to repot such plants, it is better that they should be in good, fresh material that they can root into than be struggling for existence in a compost that has become sour through some cause or other. Masdevallias and Odontoglossums are both very impatient of any serious disturbance at the roots in the process of repotting. A moist, cool atmosphere is good for the plants, but too much may cause the delicate flowers of the Odontoglossums to spot and decay much before their time. A little frost at night prevents the blump from doing my injury.

FERNS.

NOTES AND REPLIES.

Growing Ferns (F. G.).—A northern aspect is as good for Ferns as any other, and, if the walls are not too high, yours is a rather favoured position, and if expense is a secondary consideration we should advise having a good heating apparatus to begin with. In a house heated by hot-water pipes there could be grown not only a better class of Ferns than could be grown in an unheated house, but certainly of the

greenhouse plants, notably the Date Palm (Phoenix dactylifera), Latania borbonica, Corypha australis, and several of the Arecas, Chamaerops, &c.; also Indian-rubber plants (Ficus elastica), Crocodylia robusta, several of the Dracaenas, and many other useful table plants. The house would, however, be too staid to grow flowering plants satisfactorily. Even if hardy Ferns only are to be grown, it would be well to lure heat enough to expel damp and stagnant air.

How to treat Adiantum trapeziforme.—I will be grateful for a little information as to how to treat Adiantum trapeziforme. I had one last summer which did well, but it now shows no sign of life. I have no heat in greenhouse. Must this Fern have heat to start, also A. Neo Caledonia and Cheilanthes radiatum?—St. John's, Jersey.

[We are afraid that your plant of Adiantum trapeziforme will never start again, even if heat is applied to it now, as in all probability it is quite dead, the result of wintering in a cold house. It is a native of tropical America, and to succeed with it it needs the temperature of a stove, in which structure the fronds are retained throughout the winter. True, in the height of summer it may be kept without fire-heat for a time, but as soon as the nights get cool additional heat is very necessary. If your plant happens to possess any life, a little bottom-heat now may cause it to start, but, as above stated, there is not much hope. The same remarks will apply to Adiantum Neo Caledonia, a native of New Caledonia, and Cheilanthes radiatum, which grows in tropical America and the West Indies. While the three above-named Ferns are all very beautiful, they are by no means such as can be recommended for growing permanently in a cool-house, even in your favoured climate.]

Fern fronds turning brown (A. Y.).—It is impossible to tell the actual cause of the Fern fronds turning brown, as it is not stated whether the Fern is in a room or greenhouse. It may be caused by the Fern being grown in a moist, warm greenhouse before it was purchased, and then being suddenly changed to the dry air of a living room; or it may be through plunging it from a close greenhouse to a very dry one, or from its being kept too near the glass in the full sun. It should be borne in mind that the fronds of Adiantum gracillimum are naturally brown in a young state, changing to a light green when full grown, but as you say it is growing all right, there is no harm done beyond the loss of a few fronds. This Fern requires in spring a night temperature of from 50 degs. to 55 degs., with a rise as the season advances; it should be kept 4 feet from the glass, and shaded from bright sun. The air of the house in which it is grown should be kept moist by damping the walks, etc., pretty frequently, but avoid syringing much overhead. Air should be given on favourable occasions from the top lights only, thus preventing sweeping draughts.

GARDEN PESTS AND FRIENDS.

Destroying ants.—Will you kindly suggest any means for the extermination of ants from my Strawberry-bed? Last year the whole crop was devoured by them before they were ripe. The plants are now full of bloom, and as yet no appearance of ants. Can anything be done to destroy them without injury to the plants? The bed is near a stone wall.—H. RIDGE.

[The only thing you can do is to search for and find out their nests, which are, no doubt, at the bottom of the wall. Into these nests pour boiling water, which will at once destroy them.]

The Vine-weevil (Olfiorhynchus sulcatus).—I have noticed lately that some of the leaves in my vineery are split, and in one or two cases eaten away by an insect. After making careful search I discovered two or three beetles, specimens of which I sent you. The same insect has also been found in the Peach-house, where great havoc has been wrought to the leaves. I have caused careful search to be made all through the Peach-trees, and have captured a couple of dozen of them. Would you be kind enough to tell me what they are, and the best means of dealing with them? I cannot find out where they secrete themselves or breed. Would they live in the ground, or in the walls adjacent to the trees? Both the Peach-trees and the Vines are in heated houses. I have sent you samples of the leaves.—R. HUBBINS.

[The above is the name of the insect, specimens of which you sent. The only way to get rid of this pest is to catch it at night by laying a white sheet or white paper under the Vines and throwing a bright light on them. This will cause the weevils to drop, when they may be gathered up and destroyed. It is also possible to give the trellis a good shake to

bring down any that may be left among the Vine shoots. Allow no plants of a tufty nature, such as Ferns, Spineas, etc., to stand near the Vines, as in these the weevils hide away, to come out at night and destroy the Vines.]

FRUIT.

PEACHES FAILING.

I SHALL be much obliged for information as to failure of Peach-trees. The wall on which they are placed is a concrete retaining wall about 8 feet high, with the surface smoothed over with plaster. There are pilasters along the wall at intervals, and the trees are placed between these. The wall is not quite straight, but slightly curved, the convex side to the north so that the curve is open to full south. The trees first planted grew to a full size and bore fruit exceedingly well. At last they withered and failed. The soil was dug out and changed, and new trees planted, but they died the second year. The process was repeated, and again the trees died. An Apple-tree put in the place of one of the Peaches seems doing well, and Fig-trees thrive at each extremity of the wall.—C. JONSTON, (Reas. Abingdon).

[The failure of your trees seems to us to point to unsuitable soil, drought, and summer treatment. The fact of your trees flourishing once, and then failing from canker, shows that there was either a soil deficiency, or an excess of some mineral unaccounted for to the roots. What that may be can only be determined by expert analysis and cultural experience. Your young trees may fail to grow if, when planted, they were not mulched to keep out the summer drought. The nature of your wall is that which would probably increase heat absorption, both in the soil and about the trees themselves. Moisture is a great factor in the successful establishment of newly planted trees, and overhead syringing, too, is necessary each evening when the weather is warm and summer-like. Red-spider quickly establishes itself on trees that unduly feel the heat. There are soils in which Peach-trees develop canker before they attain to any great age, even when cultivated under glass. Soils in which there is an excess of iron we have known to develop this failing. Lime is an important component part of Peach soil, as is also burnt ballast. This latter is not, however, absolutely necessary though useful, but lime is prescribed by most practical gardeners for almost every soil. Peach-trees should be planted in early winter or while there are still leaves unshed. Moved thus early and carefully planted, roots at once form in the new soil, which when spring comes round are a great incentive to a good start. When planted late they have not this opportunity. The soil, too, should be made quite firm; if too wet at planting time to allow of this, make it firm later on when excessive moisture has abated. The Fig would possibly thrive where the Peach with the same conditions would fail; Fig-trees have more resisting powers, and are no guide as pointing to the suitability or otherwise of the site or soil for Peaches. Briefly, we advise planting young trees in November, incorporating lime in the soil and making it firm; mulching with either short or strawy manure, and pruning in February. Newly purchased Peaches should be shortened back at least a third of the branch area, so as to build up a more vigorous foundation for the future.]

NOTES AND REPLIES.

Protecting fruit from birds.—A simple and inexpensive way of protecting fruit from birds consists in hanging a small mirror on the top limbs of the tree. There should be at least 6 inches of string to the mirror, so that it can swing about as it is blown by the wind. The flash of the mirror warns the birds away. One or two mirrors hung on a tree are sufficient.

Peach-trees shedding their leaves.—I have forwarded you a few Peach-leaves to see what is the matter with them. The trees once were very neglected, allowed to grow any way, and to get as dry as powder. There is a splendid set on them, but there is a lot dropping off in the staining. I have thoroughly soaked the border with water, but when I syringe the leaves drop off. Do you think it is a disease?—HENRY HUBBINS.

[We do not know of any disease to which Peach-trees are afflicted likely to bring about such a state of leaf-dropping in early spring. It is more likely the outcome of neglect in the past. It is most unusual for leaves to fall in spring, and those you send, apart from their thinness and absence of vigour, appear to have been sun scalded. This would happen if the soil were allowed to become dry, or if the leaves were moist when there was insufficient ventilation in the hot sun. The fact of the fruit dropping off

when stoning, shows that there has been a serious inattention at the roots, not perhaps this season so much as in the past. Keep the borders well, though not excessively, moistened, and if you have not given them any fresh soil this winter do so as a top-dressing at once, with an additional dressing of some artificial manure. Attend closely to the ventilation of the house and the daily syringing when there is sunshine, and keep a constant and gentle heat in the hot-water-pipes, especially at night. See to the summer shoots often, cutting out those unnecessary, and tying in the rest to furnish the trellises thinly. Do not be concerned about the present crop so much as that of getting a restoration of health and vigour for the future. There are time and opportunity yet to do this, and by the autumn to have well-ripened wood for next year.]

Fumigating Muscat of Alexandria Vines.—Kindly tell me why anyone must not fumigate Muscat of Alexandria and Lady Bowen's Grapes with XI. All? Would it do them any harm now they are in bloom?—**CIRELTON.**

[From the earliest trials of the XI. All mixture it has been proved that the chemical constitution of the article is injurious to the Vines named, and this being so, growers wisely abstain from running the risk of injury in acting contrary to the instructions issued with the preparation. What the injury takes the form of we are not prepared to say, it being sufficient for us to know that there is a risk in its use. We should certainly abstain from fumigating any Vines when in flower, and there should be no need to fumigate Vines at such an early period of the year. It augurs badly for the summer progress of the Vines if fumigation is necessary now.]

Scale on Peach-trees.—My Peach-trees, which are under glass and have fruit on them about the size of pheasant's eggs, are covered with scale. What can I do to kill it? I have tried fumigating, but that has no effect.—**CIRELTON.**

[There is nothing so simple or effective for removing the scale which has recently hatched than using a pointed stick, an old knife, wood label, or something similar, to scrape the scale off. There is no insecticide you can use with safety now, and scale insects are not much influenced by fumigation. It may seem a laborious undertaking to deal with them thus by hand, but in the actual work this is not found to be so. It is mostly on the old wood and that of last year that the scale becomes established, and not on the current shoots and leaves. To use a concoction of any insecticide sufficient in strength to destroy scale would roast certainly be harmful to the fruit now so far advanced, because of the down-like surface of the Peach absorbing and retaining a taint until ripe.]

Unfruitful Pear-tree.—I have a Pear tree trained up the side of my house. It looks healthy and makes much wood, but has not flowered during the last four years that I have been here, yet I am told that formerly it produced largely. Two years ago I opened up the roots, cut out a large tap-root which struck down into clayey soil, and put in good mould with some manure; still there are no flowers. Can you suggest any treatment?—**J. J. B.**

[You did right in severing the tap-root which descended into the clayey soil. But are you sure there were no others? There is often much gratification in the discovery and operations of this nature, but if search is not made for further offending thong-roots, and if these exist then barren trees remain barren, simply because their vigour is not sufficiently restrained. Another course, however, is open to you, that is, instead of pruning in the orthodox manner, allow the leaders to extend without pruning, and if there is room nail a lateral shoot here and there between the main branches. This course without root amputation sometimes changes the order of things. You do not say what is the name of your Pear, but we think it may probably be Jargonelle, often a shy-fruited variety, especially so if it is kept too closely pruned. We have seen trees of this kind remain unfruitful over a long period from a wrong course of pruning, and when treated more liberally respond at once to the change, bearing fruit, not on the old and hard-spurred portions of the tree, but on the young growths that had been laid in during the summer. Hard pruning promotes vigour, which in time gives rise to barrenness in many kinds of Pears, while others are not so

influenced. Soil, however, plays an important part in the conduct of the Pear-tree, whether for good or ill. A freer extension of the head may bring about the necessary change. If it does not, then further search for thong-roots may be necessary.]

Watering inside Vine borders.—If the roots are likely to require more water before the Grapes are ripe, no time should be lost in giving them a sufficient quantity, free from stimulants and at a temperature ranging from 80 degs. to 90 degs. A mild bright morning is the best time to apply it, and if requisite a light mulching may be spread over the borders to prevent its too rapid escape from the surface. Atmospheric moisture must also be regularly supplied, otherwise red-spider may put in an appearance and become very troublesome before the Grapes are fit for cutting. Early Grapes ripened during a rising season require and carry off a great deal more moisture than would be good for late crops; hence the importance of keeping the mulching and all available spaces well moistened with pure water and stimulants alternately. Many growers now make very little difference either in the quantity or quality of the water used for damping down with, but follow up the usual practice in all early houses until the Grapes are ripe.

BOOKS.

"THE BOOK OF VEGETABLES."*

THE seventh volume of Dr. Roberts' handbooks on gardening, which bears the above-named title, has now reached our hands, and, after carefully reading the seventy odd pages comprising the practical portion of the work, we have pleasure in commending it to the notice of those of our readers who wish to excel in the cultivation of the vegetables enumerated therein. We make this latter reservation because the writer—who it may here be stated is Mr. Geo. Wythes, head gardener to the Duke of Northumberland, Syon House, Brentford—was unable to deal with all kinds of vegetables in consequence of the first volume of the series having been devoted to the culture of such crops as Asparagus, Celery, Seakale, etc., hence their omission from the volume under review. Those not possessing Vol. I. will find this a drawback, but it is also one that they can remedy at a very modest outlay; in fact, everyone interested in gardening is advised to become the possessor of the whole series as issued up to date.

The pages of "The Book of Vegetables" teem with useful, practical information, both as to the time when to sow the various crops, how to do it, also as regards their after management, and, coming as they do from the pen of a skilful cultivator, those lacking the experience cannot err if they do but adhere to the simple rules laid down, and adopt the cultural advice tendered. The author devotes lengthy chapters to the growing of those two important crops—Peas and Potatoes—and makes allusion to such varieties as he finds to succeed well with him, which, by the way, are mostly to be found in general cultivation. Regarding the forwarding of early Potatoes, many gardeners living in country districts where tree leaves can be had in abundance should make special note of Mr. Wythes' method of obtaining them, which consists in forming a large bed with the leaves in some sheltered spot open to the south, on which suitable soil is spread to the requisite depth, and performing the planting of the tubers early in March. The genial warmth engendered by the leaves promotes quick growth, and the crop is ready for lifting far in advance of that grown on a south border. Protection from frost, it may be mentioned, is afforded by straw-thatched hurdles, and the employment of Bracken, cut in a green state and sun-dried, is also recommended. This is, perhaps, not altogether a new idea, nevertheless it is one that might be more generally adopted than it is, and that with excellent results. Mr. Wythes has a good word to say for that fine main crop Potato Windsor Castle. Modesty, of course, forbids him to

* "The Book of Vegetables," by Mr. Geo. Wythes. Edited by Dr. Harry Roberts. John Lane, The Bodley Head, Vigo-street, London, W.

make more than passing mention of those two esteemed varieties, for the raising of which he is responsible—viz., English Beauty and Syon House Prolific. Having grown the two sorts extensively since their introduction, we are in a position to say that they occupy front rank in their respective classes, the first-named being a first early and the last a very late kind; in fact, in our opinion, no other late Potato surpasses it for general excellence. The remaining portion of the volume is given up by the editor to the history and cookery of vegetables, and in addition to the information afforded as to the derivation of the names of and the antiquity of many of our common vegetables, the reader will find most valuable recipes for the cooking of the same in various ways, many of which will no doubt be quite new to the ordinary housewife.

THE BEST HARDY PERENNIALS FOR CUT FLOWERS.*

AMONG the many books on gardening coming out now those with coloured plates are not so common, and this rather large book consists of a series of coloured plates of some of the bolder hardy flowers, some of which are good, some inferior, and all rather marred by a dull grey background which gives monotony to the plate. The matter, by Mr. F. W. Meyer, of Exeter, is as good as it can be, and follows the illustrations closely. It is impossible in such a work to do anything like justice to the immense number of hardy flowers we have in cultivation. The following about borders, however, is sound and good—

"There can be no doubt that the most effective border is that which has an irregular outline, and is arranged against a background of ornamental trees and shrubs. As a rule such borders are not made nearly wide enough to allow all plants to develop their full beauty without becoming overcrowded. Now and then the choicest shrubs of the background should project into the border and mingle with the hardy flowers, while in other places the border itself should break the line of shrubs by forming here and there a deep recess among the taller plants. Such a border should never be dug over (unless in the course of years it should require to be altogether rearranged), and it should never show a single yard of bare soil either in winter or summer, and in this direction I think the borders of most gardens may be greatly improved. The worst fault of most borders is that they are generally arranged with far too much regularity. As a rule people are content to have their tall plants in the back and the small ones in the front, leaving the ground between perfectly bare. The result is a more or less regular bank during the summer months and a bare hill during winter. But there is just as much difference between this and the picturesque style of arranging borders as there is between a group of lovely Orchids and a choice stove and greenhouse plants arranged for effect at one of our principal exhibitions, and another group forming a more regular bank of flowers and foliage arranged with much painful exactness, that its outline might be compared to the sloping roof of a house. In a well arranged group, as now often exhibited for effect, we have short plants among taller ones, springing from a dense carpet of Maiden-hair Fern or other greenery, studded with flowers, but all plants are or should be so placed that the eye can penetrate and admire the full beauty of each individual flower or fine foliated plant, while the whole combination has a most pleasing and graceful effect. Why is it that plants grouped in this manner and often, as it were, a series of vistas, through which the shorter plants are distinctly visible, are so pleasing to the eye? It is because this combination produces different effects of light and shade, and each visible short plant through the taller ones becomes in itself a picture viewed through the living frame of other plants. This, then, is the style which should be our pattern when grouping plants out-of-doors; it is on the principle of the true style of Nature and will lend itself to an infinite number of most effective variations. Instead of leaving the soil bare between the taller plants, let us carpet it with flowers and greenery, just as Nature would clothe the bare soil of our woods with all kinds of dwarf vegetation, as we now do in the case of a group of Orchids arranged for effect at an exhibition. We have an endless variety of hardy plants suitable for the purpose. What would be prettier than a colony of bright flowers springing from a carpet of the woolly Thymus serpyllifolius, or such plants as Helianthus glabra, Arenaria capitulo, or any Savitilla, Veronica repens, etc.? Or if we desire a series of lighter colour, we have Phloxes, Veroniceas, Er. annua, Alyssum Aralis, Aubrietia, Iberis, Campanulas, and scores of other varieties to choose from. Surely there is no excuse for bare spots when we have such delightful evergreen plants to cover the ground."

United Horticultural Benefit and Provident Society.—The usual monthly meeting of this society was held at the Calcedonian Hotel, Adelphi-terrace, Strand, on the evening of May 12. Mr. Joseph Wheeler presided. The minutes of the last meeting were read and confirmed. Nine new members

* "The Best Hardy Perennials for Producing an Abundant Supply of Cut Flowers and for Effective Displays of Bright Colours in the Garden," with coloured plates. By F. W. Meyer. Blake and Mackenzie, School Lane, Liverpool.

were elected, making fifty-three in the five months this year. Three members were reported on the Sick Fund. The death certificate of the late Mr. Crawford was produced, and £18 1s. 11d., being the amount standing to the late member's credit, was voted to the widow, also a cheque for £5 from the Benevolent Fund, this being considered a very urgent and deserving case for assistance.

LAW AND CUSTOM.

Discharge of sewage into neighbour's ditch—easement.—Sixteen years ago I erected a detached house in a rural parish where there was no system of sewers. Before the sanitary inspector would grant a certificate of habitation he required me to make a cesspool for reception of soapy water, etc. (there is no s.e. in the house), with an overflow from the cesspool into my neighbour's ditch. I endeavoured to avoid any overflow there, and use a measure-pump. After sixteen years' enjoyment can my neighbour object to the overflow passing into his ditch? If he may successfully object, cannot I turn the overflow into my own ditch in front of my house and leave it to find its own way into other ditches? Or can I be compelled to enlarge my cesspool, so as to stop the overflow altogether?—TORONTO.

[You have gained no right by sixteen years' use, and your neighbour may compel you to divert the overflow of your sewage from his ditch. You may turn the overflow from the cesspool into the ditch at the front of your house, as this ditch is your own; but, as this ditch adjoins a highway, the overflow may be the cause of a nuisance and may be offensive there. In that case you will be liable to proceedings for causing a nuisance, and you may be compelled to drain into such a cesspool as may be adequate and also to clean it out from time to time, as circumstances may require. The local authority are not bound to provide an expensive system of sewerage merely to meet the requirements of one house. You choose to erect your house in a detached position where there was no sewer available or within a reasonable distance, and you must abide by the consequences.—K. C. T.]

A garden tenancy.—I have a small nursery as a nurseryman, florist, and fruit-grower, and for my use as such four years ago I took an acre of land which had previously been used as the kitchen garden of a private house, the owner not requiring it for that purpose any longer. It was in a very dilapidated condition, and only had upon it a few old standard fruit-trees, which still remain. My agreement is so much rent per annum, payable half-yearly, but the tenancy can only be determined at Christmas by either party giving the other six months' notice in writing. Since I have been the tenant I have cleaned and manured the land, and planted some in gooseberries, currants, and raspberries, and over 2500 Strawberry-plants, one-half of which were young plants from pots planted last July. My landlord now tells me he will require the garden again, and he is intending giving me notice in June next. Must I remove all the things I planted? Or can I leave them, and claim compensation from my landlord when I give up at Christmas? And how must I then proceed?—THE EDITOR.

[You do not say if the agreement states that the garden is let to you as a market garden, or if it permits you to use the garden as a market garden. No doubt you do so use it, and it would be expected by your landlord that you would so use it, but unless it was agreed in writing that the holding shall be let or treated as a market garden, the holding does not come within the Market Gardeners' Compensation Act. If it does come within that Act, you may, on quitting, claim compensation for the unexhausted value of the manures purchased and used, also for the fruit-trees and fruit-bushes permanently planted out by you. And you may remove, before your tenancy expires, all fruit-trees and fruit-bushes planted by you, but not permanently set out. You may also claim compensation for all the Strawberry-plants planted last year, but for none planted as you became aware that your tenancy would be determined at Christmas. You would not be able to claim for any vegetable crops planted during the last year of tenancy, although you may remove all such before you quit. If the Market Gardeners' Compensation Act does not apply, you cannot remove any of the trees and bushes permanently set out, and you cannot enforce any compensation for them unless such is given in your agreement of tenancy or by local custom, and I do not profess to be intimately acquainted with market garden custom in your district. If the agreement did not state that the place was let for cultivation as a market garden, it was the height of folly to plant all these trees and bushes without some security for compensation.—K. C. T.]

POULTRY.

POULTRY IN CONFINEMENT.

(REPLY TO "K. W.")

THERE is no necessity to keep a male bird with hens that are merely required to produce eggs for home consumption. There would be no difference in the flavour of the eggs if no cock were kept. As to feeding, the best rule to follow is to give soft food early in the morning (in a warm state during the winter months), consisting of Barley-meal, to which may be added a good proportion of sharps or pollard during the summer. This paste should be of a stiff nature that will easily crumble and fall to pieces when thrown on the ground. Turnips, Carrots, and other vegetables, if boiled and mixed with soft food, conduce to good health, and are especially valuable if the fowls have not a Grass run. Kitchen scraps may be given at midday, and always good sound grain at night before roosting time. The hard grain should consist of Barley, Wheat, Maize, and Buck-wheat, given in turn, as a frequent change of food is much to be recommended, being far better than the constant use of one kind of grain. Maize must, however, be used somewhat sparingly, as it is not to promote the formation of internal fat, and fat hens seldom lay well. It is important to avoid over-feeding, for, whether by excess of quantity or of stimulating constituents, over-feeding is the cause of most of the diseases that fowls are subject to. In commencing poultry-keeping it is important to secure young birds only; those hatched in March or early in April are the best. These should begin to lay at six months old, and with good management continue to do so throughout the winter. When ceasing to lay they are in prime condition for the table, or they can be kept on till the following autumn. By this time they will have laid their second lot of eggs, and be about eighteen months old, and this is the age at which most of the hens should be cleared off—either sold or used for table. Their flesh at this age is good eating, and possesses a firmness not met with in a chicken of the year. Another lot of early-hatched pullets should then be purchased. In this way poultry-keeping will often be more profitable than if chickens are bred for stock purposes. You will find "Popular Poultry-Keeping" useful in the management of your fowls. It is published at 170, Strand, London, W.C. (1s. 2d. post free). S. S. G.

Death of hen (Broun-eye).—This appears to be a case of apoplexy, a complaint to which laying hens are very subject, being usually the result of an obstruction in the circulation of the blood, causing a sudden rupture of one of the minute blood-vessels in the brain. The only remedy is bleeding, by opening the large vein under the wing, making the incision lengthways, and pressing the vein with the thumb between the opening and the body. Apoplexy can seldom be treated in time to be of any value. If the patient should recover it must be kept very quiet for a few days, and fed upon soft, non-stimulating food. High feeding promotes a tendency to this complaint, therefore robust, heavy birds should be carefully fed, especially if they are disinclined to take much exercise. Should any of your other hens show symptoms of apoplexy, give a dose of castor-oil and feed low.—S. S. G.

BIRDS.

Death of Canary (Frenshwa).—This bird had been ill for some time, and all the internal organs were in a very diseased condition. The journey by rail may possibly have hastened its death, but under the most favourable conditions it could not have lived more than a week or so. Fatty degeneration of the liver appears to have been the immediate cause of death. This was probably brought about through injudicious feeding, food of too stimulating a character having been supplied.—S. S. G.

Canary ailing (F. E. Whithy).—As symptoms does not ease the "bad croaking" and I can describe the symptoms of the

complaint from which your bird is suffering, you might try a little oxymel of squills, giving two drops three times a day, keeping the patient in a high, even temperature day and night, as it appears to be suffering from an inflammatory affection of the lining of the bronchial tubes, which was, no doubt, caused through its having been removed to a colder climate than it has been used to. Give green food freely in the form of Watercress, Lettuce, and Groundsel, and do not omit that almost necessary health-preserver, cuttle-fish bone, a piece of which should always have a place between the wires of the cage near the perch. Avoid an exhausted, dry atmosphere, such as is found in the upper part of a living-room, especially where gas is burned. It is just in such a position that birds contract bronchitis, and this in its chronic form is one of the most common complaints from which cage-birds suffer.—S. S. G.

Death of young Pigeons (Moose-llide).—It is rather unusual for young Pigeons to die off in the way yours have done. Do you let them have a liberal supply of salt? This is essential in keeping these birds in health, as is also a good allowance of old mortar broken up. Plenty of fresh water, to drink and bathe in, is all-important. Some of the prepared gravels that are sold for Pigeons are excellent for keeping them in health and condition. It would be well to discontinue the Beans, giving Maple Peas, Tares, and Duri. When young Pigeons become thin and light, cod-liver-oil capsules are given, one every evening for about ten days. These generally pick them up wonderfully. Afterwards, a little Canary-seed and Hemp-seed are given. The nest-pans that contain your Pigeons should frequently be cleaned and receive fresh sawdust, in which a few drops of paraffin or turpentine have been sprinkled to keep insects in check. The shelf on which the nest-pans rests should also receive some paraffin, for it is here that the insect pests usually congregate. There should always be a lump of rock salt accessible to the Pigeons, and also a good supply of small gravel to assist in the digestion of the food. No bird can long remain in health without sharp grit in the gizzard.—S. S. G.

Canary losing its feathers (No Name).—The loss of feathers at other than the usual moulting season may arise from an irritable condition of the skin, which is often associated with indigestion or the presence of insect pests in the cage. A gross condition of the system brought on from a bird being allowed to partake too freely of sweet cake, sugar, or egg-food, will also cause loss of feathers. You do not give any particulars as to diet and general treatment. In a case of this kind, the diet, while nourishing, must not be of too stimulating a nature. While abundance of green food should be supplied, of which there is nothing better than the flowering tops of Groundsel, give also a little Linseed, which is very useful in helping Canaries over their moult. Lettuce-seed, if given, acts as a slight purgative, and cools the system. You would find a few drops of Parrish's Chemical Food daily in the drinking water greatly assist your bird in its protracted moulting. This excellent preparation contains all the elements necessary to the elaboration of new feathers, while giving tone to the system. Maintain as even a temperature as possible in the room where the bird is kept, but especially guard against hugging the cage high up on a wall in a room where gas is burned, as in such close and poisonous air no bird can do well. Supply an abundance of grit-sand, with some old powdered mortar, but no sweets of any kind, as these in any form are very injurious to cage-birds.—S. S. G.

Photographs of Gardens, Plants, or Trees.—We offer each week a copy of the latest edition of the "English Flower Garden" for the best photograph of a garden or any of its contents, indoors or outdoors, sent to us in any one week. Second prize, Half a Guinea.

The Prize Winners this week are: 1, Mrs. F. C. Watson, Great Staughton Vicarage, St. Neots, for border of mixed annuals; 2, Mr. F. Parkins, Pepper Arden, Northampton, for

fall in the manner indicated they may
out at once, as the fruit on them
drop off. The decay of bark

and stem partakes somewhat of the form of
canker, and according as sap communication is
cut off from the roots the branches will fail.
Gumming is sometimes responsible for these
occurrences, and strong sunshine pouring
direct on the stems is thought by some to
injure the bark, slow decay resulting, while
faulty stocks are also blamed for some failures.
Whether this cankerous affection is the result
of a bad bruise of stem or sunburn we are
unable to decide, and can only advise cutting
away all dead portions of bark, neatly round-
ing off where sound, and then coating with
clay and manure to facilitate the formation of
fresh bark. In any case it is advisable to com-
mence the preparation of a young tree to take
the place of that failing, taking care when
moving the former in the next or following
autumn to give it the benefit of quite fresh
loamy soil. Should the other trees give signs
of becoming sickly, then there is most prob-
ably something seriously wrong at the roots,
nothing short of lifting and replanting in
fresh fibrous loam to which bone-meal and
"burn-bake" have been added, using the latter
freely, being of any use. This lifting should
be done in the autumn after the wood is well
matured and before the leaves have fallen.
Peach and Nectarine trees pay well for this
treatment whether they are in a sickly state or
not. Some of the most successful growers
give their trees the benefit of a fresh supply of
loam every autumn.]

FIG CULTIVATION IN THE NORTH OF FRANCE.

It may interest our readers to know the kinds
of Figs that are found to do best in the North
of France, where the conditions of climate are
something like our own. Some of these kinds
are not known in England, though well worth
a trial, especially in the warmer and southern
parts of the country. Fig à trois récoltes is
the earliest Fig of all, being ten days earlier
than Blanche d'Argenteuil; Adam, an early
ripening; Blanche d'Argenteuil (known also
as Varsaille, Madeleine); Dauphine (or
Grosse Violotte), a half-early kind; Bar-
billonne, a few days earlier than the
preceding; and Rouge de la Frotte, a slightly
later variety. The causes of sterility in Fig-
trees are various—for instance, an unfavour-
able position, or neglect and over-rank vege-
tation. In a climate like that of Paa-de-Calais
and the Paris region the Fig-tree requires a
light, warm, and fertile soil, and special care
in cultivation—e.g., pruning, disbudding, reduc-
tion of wood to facilitate earthing-up during
winter, treatment of the fruiting branches,
and the various cares to be bestowed during
hard winters and in spring.

NOTES AND REPLIES.

Caterpillars and Apple-trees.—As far
as garden trees are concerned, it is scarcely
advisable to resort to spraying with poisonous
mixtures. Syringing the trees forcibly with
soapy water would dislodge a good many, but
either caterpillars, or these after they have

changed into the pupa state, that cannot be
thus got off, owing to being snugly enclosed in
the leaves, should be picked off by hand and
crushed. If the trees are large and have to be
sprayed over with Paris green—the arsenical
insecticide most favoured by market growers—
mix this at the rate of 1 oz. to 20 gallons of
water. The powder should be first made into
paste and it will then readily mix with the
water. It should be used in the form of the
finest spray possible. One application will not
be sufficient, but about three at intervals of
about four or five days ought to quite rid the
trees of caterpillars without detriment to the
crops.

Liquid manure for fruit-trees.—
Now is the time to apply liquid manure to
fruit-trees, especially to Apples on the Paradise
and Pears on the Quince, which require much
moisture owing to the limited extension and
meagre depth of the root-run of these dwarfing
stocks. A fruit-tree in bloom, which is in
vigorous condition and able to imbibe by its
roots all the nourishment requisite at that
critical period, will not only throw off or over-
come the various forms of blight, but will with-
stand frost better, owing to the greater luxuri-
ance and protective influence of its foliage,
than the tree which, through drought, exhaus-
tion, or poverty of soil, has enough to do just
to keep alive. From the former you may
expect a good crop of fruit, from the latter
none. I have plenty of trees promising again
for a good crop on which I should scarcely
have expected to see even a blossom, so heavy
was the crop of fruit they carried last season,
if they had not been assisted with liberal dress-
ings of artificial and liquid manure.—B.

Peach and Nectarine-trees blighted.—Some
—I may say all—of my Peach and Nectarine-trees are
shrivelled up and covered with aphid. I might I have
syringed them this cold weather? 2. If so, what decoction
is most effective?—F. H. L.

[It is not a good practice to syringe outdoor
trees when the weather is so cold, as of late,
although when signs of insect troubles are
apparent there is usually a time when it can
be done. If syringing cannot be practised,
Tobacco powder can be dusted into the curled
points, and this will destroy aphid quickly.
The "Abol" insecticide is one of those you
can procure and use with effect and certainty.
Something of this kind should always be kept
in stock by those having the care of fruit-
trees, because the necessary delay in getting
it may spell ruin to the existing prospect and
crop. Yours must be a bad case, and will
need energetic action to stay its progress.
Once the leaves curl up insects are difficult
to reach with either powder or insecticide
washes, and it is often labour well repaid to
syringe the trees in spring, even before an
insect is detected. Picking off the first few
curled leaves is sometimes the means of
keeping these troubles from getting the upper
hand. Trees are soon badly crippled when
insects are allowed to become established on
them, as they not only damage the existing
foliage, but sometimes cause the fruit to col-
lapse, however well set it may be. You
cannot do better than pick off the worst
leaves now and burn them.]

PLANTS AND FLOWERS.

OUTDOOR PLANTS.

ROCK GARDEN HAIRBELLS
(CAMPANULA).

A LARGE family of northern pasture, mountain and alpine plants; many of these last among the best for the rock-garden dwarf, graceful in form, lovely in colour, and for the most part easy to grow and increase. The tall parentals are too coarse for the rock-garden, and neither these nor the medium-sized kinds require its aid, growing, as they do, freely in any soil; but the dwarf mountain kinds are essential to its beauty—all the more so as they rarely demand any special position, but may be grown in chinks or between steps on any aspect. Where there is no good rock-garden they may be grown well and with good effect behind and about stone or flint edgings. Among these plants garden hybrids are not now uncommon, but it is better on the rock-garden to keep to the wild forms. Some hybrids, however, like G. F. Wilson, are pretty. Ordinary garden soils suit well even the mountain kinds, with a little change in the case of the kinds inhabiting high moraines, and a rather peaty loam for the graceful *C. pulchra*. In congenial soils they bear seed freely and often sow themselves. In a numerous group like this, where beauty of effect is sought, we arrive at it more surely by growing well and placing rightly the more beautiful kinds, than by collecting every kind we can.

The following Hairbells are mostly of dwarf stature, natives of rocky or mountain ground, excluding the more vigorous herbaceous kinds as unfit for the rock-garden and delicate or doubtful species. They will fairly represent in the rock garden and on walls the beauty of a family of northern and high mountain plants—many of which are not in cultivation:

C. ALLIODI (Alliodi's Hairbell).—A dwarf kind, the flowers very large for a plant growing

stones and grit. Flowering summer. Piedmont. Syn., *C. alpestris*.

C. ALPINA (Alpine Hairbell).—This is covered with stiff down, which gives it a grey hue, with longish leaves and erect, not spreading, habit, like the garganica group, and with flowers of a fine dark blue, scattered in a pyramidal manner along the stems. It is a native of the Carpathians, harder than the dwarf Italian Campanulas, and valuable for the margins of

The Tufted Hairbell (*Campanula caespitosa*).

bordered as well as for the rock-garden. In cultivation it grows from 5 inches to 10 inches high, and may be readily increased by division or seeds.

C. BARBATA (Bearded Hairbell).—One of the blue Hairbells that abound in the meadows of Alpine France, Switzerland, and N. Italy. It is readily known by the long beard at the mouth of its pretty pale sky-blue flowers, nearly 1½ inches long, nodding from the stems, which usually bear two to five flowers, and rise from rough, shaggy leaves. In high ground in its native country it grows no more than from 4 inches to 10 inches high, but nearly twice as high in the valleys in Piedmont. It is suitable for rock-work, or the front margin of the mixed border, though not a showy plant, is easily increased by seeds and also by division, and flowers in summer. There is a white-flowered form, both thriving freely in loam.

C. CAESPITOSA (Tufted Hairbell).—One of the most beautiful plants in the alpine flora, abundant over the high ranges in the central parts of Europe, and thriving in all parts of the British Isles. It grows only a few inches high, and looks the same fresh, purely-tinted, ever-spreading, and bravely-flowering little plant in a British garden as it is when seen mantling round the stones and crevices of rocks on the Simplon. There is a white variety as pretty as the blue, and both are admirable for the rock garden or mixed border, and also as edging plants. It is easily increased by division and also by seed, but as a few tufts may be divided into small pieces, and quickly form a stock large enough for any garden, it is scarcely worth while raising it from seed. As it occurs so freely by the road sides along the road-ways into Italy it was one of the first alpine plants to be grown in Britain, and thriving so well in our climate it is the one so often seen. Syn., *C. pumila*.

C. CARPATICA (Carpathian Hairbell).—This, while bearing cup-shaped flowers as large as those of the Peach-leaved Hairbell, has the dwarf neat habit of the alpine kinds. It is a native of the Carpathian Mountains and other parts of the same region, and fortunately easy of culture in all parts of these islands, growing from 6 inches to over a foot in height, according

to the depth, warmth, and richness of the soil. It begins to flower in early summer, and often continues in bloom for a long time, especially if the plants are young, and the seed-vessels be picked off. There is a white variety, *C. c. alba*; a pale blue one, *pallida*; and a white and blue kind, bicolor—names for the most noticeable variations raised from seed. It is quite easily raised in this way, or increased by division, and is a most valuable edging as well as rock and border plant.

C. CESTRA (Mont Cenis Hairbell).—An alpine growing at very high elevations. I have found it abundantly among the fine *Saxifraga biflora*, at the sides of glaciers on the high Alps, scarcely ever making much show above the ground, but, like the Gooseberry-bush in Australia, very vigorous below, sending a great number of runners under the soil. Here and there they send up a compact rosette of light-green leaves. The flowers are solitary, blue. Somewhat funnel-shaped, but open, and cut neatly to the base into five lobes. It should have a gritty and moist soil, and be somewhere near the eye. Easily increased by division, and hardy. Alps of Central Europe.

C. EXCUBA.—An interesting species, usually found at high altitudes; the flowers pale blue and deeply cut. At the base between each two lobes this incision takes the shape of a round hole, and it is this which suggested the name. The whole plant is not more than 4 inches or 5 inches in height, and likes a position not fully exposed to the sun, but where the air would be cool and moist.

C. FRAGILIS (Brittle Hairbell).—In handling it the stems break off as if made of ice. It is a pretty Hairbell, the root leaves on long stalks heart-shaped in outline, and bluntly lobed, those of the stem more lance-shaped, the rather large pale blue open flowers somewhat bell-shaped, borne on half prostrate stems, the plant rarely reaching 6 inches in height, smooth and rather fleshy. A native of the South of Italy; it is invaluable for the rock-garden in well-drained chinks into which it can root deeply without being too wet in winter; on light soils not requiring this care. *C. fragilis hirsuta* is a form covered with stiff down so as to look almost woolly.

C. GARGANICA (Gargano Hairbell).—A showy kind, with somewhat of the habit of the Carpathian Hairbell, but smaller; the leaves that spring from the root are kidney-shaped, those from the stem heart-shaped, all toothed and downy. In summer the plant becomes a prostrate mass of bluish-purple starry flowers with white centres, from 3 inches to 6 inches high; it is seen best in interstices or vertical parts of the rock-garden, in warm and well

The Carpathian Hairbell (*Campanula carpatica*).

seldom more than 3 inches or 4 inches in height, purplish-blue (rarely white), almost erect on a slender stalk. It is an excellent rock plant, and though requiring plenty of moisture, it should have a well-drained position, and is therefore best grown in a narrow crevice filled with sandy loam, or a shallow bed of small

Bearded Hairbell (*Campanula barbata*).

drained spots. The better and deeper the soil the finer and more prolonged the bloom will be. It is a native of Italy, flowers in summer, and is easily increased by cuttings, divisions, or seeds.

HEDERACEA (Ivy Hairbell).—A weakly creeping thing, with almost thread-like branches,

bearing small, delicate leaves, roundish, with a few teeth; its flowers of a faint bluish-purple, less than half an inch long and drooping in the bud. However, as in the case of many other diminutive plants, there is a grace about it that would not find in more robust members of the same family; it is a native of Britain, creeping over

Brittle Hairbell (*Campanula fragilis*).

bare spots by the sides of rills and on moist banks, and wherever there is a moist boggy spot near the rock-garden, or by the side of a streamlet or in an artificial bog, it will be found worthy of a place. It occurs chiefly in Ireland and Western England; less in the east. Division.

C. ISOPHYLLA (Ligurian Hairbell).—A profusely flowering Italian species, the leaves roundish or heart shaped, deeply toothed, and nearly all of about the same size, the flowers of a pale but very bright blue with whitish centre and protruding styles. It is a charming ornament for the rock-garden, and should be placed in sunny positions in well-drained, rather dry fissures in sandy loam, and then it will repay the cultivator by a brilliant bloom. It is one of many kinds of *Campanula* that might with great advantage be naturalised in rocky spots, the sunny walls of old quarries, chalk pits, and like places. There is a white-flowered variety of this which is very effective when used in window-boxes, etc.

C. MACRORHIZA (Ligurian Hairbell).—This is one of the most beautiful of the southern plants, and one of the most free-flowering of the *Campanulas*. The root-stock is thick and woody; it throws out a large number of drooping branches; flowers very numerous, of a fine blue, two to eight in a spreading cluster. I can never forget the impression I received on first seeing it in flower in the walls of the small town La Turbie above Monaco. The little flowers were in myriads, brightening up the dismal streets of this decaying place, and giving it life and colour. It must have a vertical position in full sun, and in a fissure of

Violet Hairbell (*Campanula pulla*).

wall or rock, calcareous if possible. It is increased by cuttings, divisions, or seed.—H. Correvon (in *Garden*).

C. MOLLIS.—Though the native home of this Bellflower is on the shores of the Mediterranean, it has nevertheless proved itself to be perfectly hardy in this country and stood the test of several severe winters. The flowers are

of a dark purplish-blue borne freely during May and June, the plant from 6 inches to 8 inches high, forming a spreading carpet of glossy leaves even at midwinter. It is a very useful kind of tree dwarf habit. S. Europe.

C. MURALIS (Wall Hairbell).—This, a native of Dalmatia, is a pretty and useful plant as a dense carpet, from 6 inches to 8 inches high, with a bell-shaped corolla about 1/4 inch in length, flowering throughout the summer. The radical leaves are reniform, smooth, dark green, and more than 1 inch in diameter; the cauline leaves smaller, and with coarsely serrated edges. There is also a more robust variety named *C. m. major*. Syn. *C. Portenschlagiana*.

C. PULLA (Violet Hairbell).—A distinct plant, the stems only bearing one flower, and that of a deep bluish-violet, the habit very graceful though dwarf. On the rock-garden it should be placed on a level spot, free from other Hairbells or rampant plants of any kind, and in sandy peat. It spreads underground, and sends up shoots in a scattered manner. A native of the Tyrol and of other mountains in

Common Hairbell (*Campanula rotundifolia*).

Central and Southern Europe, it is increased by division or by seeds, and thrives very well in pans or pots and also in the open ground; but in heavy soil is apt to perish.

C. RAINERI (Rainer's Hairbell).—One of the most beautiful, quite dwarf in habit, the distinct stems not more than 3 inches long (though it is said to reach twice that height), and quite sturdy, branched, each little branch bearing a large somewhat funnel-shaped erect flower of a fine dark blue. A native of high mountains in the North of Italy, it should be grown in gritty or sandy loam, with a few pieces of broken stone half-sunk in the soil near the plant.

C. ROTUNDIFOLIA (Common Hairbell).—There is no fairer flower on the mountains than this, so often adorning roadside and hedge bank. It is well worthy of a place in the rougher part of the rock-garden. There is also a white form. *C. r. Hosti* is a variety distinguished by larger flowers of a deeper blue and by stronger wiry flower-stems, but according to Mr. Correvon, writing in the *Garden*, it is a distinct species and a native of the Eastern Alps. *C. r. soldanella* is another distinct form with semi-

double blue flowers split into many narrow divisions.

C. TURBINATA (Vase Hairbell).—A neat sturdy showy kind, the leaves rigid, of a greyish-green, toothed and pointed, forming

Rainer's Hairbell (*Campanula Raineri*).

stiff tufts from 2 inches to 3 inches high, and an inch or so above them rise the cup-shaped flowers, of a deep purple, and each nearly 2 inches across. It comes from the mountains of Transylvania, is hardy in our islands, not fastidious as to soil, and is one of the best plants for the rock-garden, and also for the mixed border, on which, in deep light soil, the flower stems sometimes reach a height of 6 inches or 8 inches.

C. WALDSTEINIANA (Waldstein's Hairbell).—A pretty little kind, 4 inches to 6 inches high, the flowers in racemes of from five to nine blossoms each, of a pale purplish-blue colour, with lobes spread out almost flat, so as to give the flowers quite a star-like appearance. Forms carpets for the rock-garden. Croatia.

C. ZAYSC.—This plant grows scarcely more than 3 inches or 4 inches in height, and bears pale blue flowers of drooping habit, with a rather long cylindrical or tubular corolla. It is not common, perishing in our changeable winters. Alps of Austria.

WATER LILIES AND POND.

MANY thanks for your kind replies to my former queries. I am now cleaning out a pond which has been neglected for years—left with the water partially drawn off, so that, having a natural bottom, great tufts of Grass and masses of weeds have grown through what ought to be a clear pond. I could not get the cleaning done sooner owing to pressure of work, and the stream which feeds it being so full in the winter. Now I am afraid it is almost too late to plant anything, such as Water Lilies, which I should like to have. I cannot count on having it ready before the latter part of this month. I do not know what I may venture to plant, as ducks will find their way to it, and the cattle must have access to drink from it at the edge. It lies in a hollow, and is fed by a natural stream. I hope

Campanula Zoysi.

It is not too shaded for Water Lilies. I should like some lilies too, but fear anything showy is liable to be picked by passing people and children, though quite on my own land. Water Lilies should be safe. Will the ducks injure them? Should I leave some mud for the Lilies to grow in? The soil is rather peaty loam. I should be very grateful for any advice.—E. A. K. W.

[You appear to be well circumstanced so far as the requirements of water-loving plants are concerned, and it is by no means too late to

introduce such things any time during the present month. If any are far advanced, which is not very likely, and suffer a little from being out of their element, so to speak, these will quickly recover when again in the pond, if care be taken of the roots and crowns. As regards the mud in the bottom of pond, you may certainly leave some of this with every advantage to the plants. The trouble comes, however, with the years of neglect, and it may be that the mud will contain many seeds of weeds that will bother you for some time. If, however, you exercise some care in the removal of the mud, and take the upper portion, you may remove much of the seed therewith, thus minimising your future labour. You do not give the average depth of pond or of mud forming the sediment, but you may certainly leave 6 inches or 9 inches for the Lilies to root into. There is nothing better than this natural food deposit, and it is rich without the grossness created by crude manures. It will be the more valuable in your case because of the peaty nature of your soil, though for starting the plants some fresh loam, with a little decayed manure, will be best. If you cannot obtain good loam or decayed turves of a pasture top spit, your next best thing is clay, or this mixed with the peaty loam. By planting in this and in some open wicker-made baskets the roots will get away in due course through the meshes. The old white Lily, the common Nuphar, and such things can be fixed by the rhizome to a stone and sunk in the mud in any position you choose. Choicer kinds are best done as first suggested. If the plants are small you will do well to make provision for them at the side of the pond for a couple of years, where, by missing the bottom, a more shallow depth of water is available. With the pond in working order and well fed, as yours appears to be, the surface should not give you much trouble. The ducks, however, will have to be guarded against, and not only these, but most waterfowl prey upon the Lily foliage as a rule, though these are less to be dreaded than voles and rats, that are not content with leaves, but often take flower buds and the roots of the plants as well. Cannot you in some way hedge off a portion with wire for the ducks, and use a little care to accustom the birds to go to this spot? If very troublesome, you could wire off a series of positions—large half-circular blocks or something of the kind—near the margin, thus leaving ample room for the birds to take to the water.

There is so much beauty in these newer Water Lilies, and they give so much greater value to the surroundings, that some effort should be made to ensure their success. The following are among the showiest and best and usually vigorous growers: *Nymphaea Marliacea albida*, snow-white flowers of great size; *N. M. chromotella*, soft yellow and cream, also large; *N. M. rosea*, rosy flesh, fragrant; *N. M. flammula*, rich claret-red, tipped white, stamens bright red; *N. Laydeckeri fulgens*, rich anaranth, crimson stamens. *N. odorata rosea*, *N. o. exquisita*, and *N. o. rubra* are sufficiently descriptive in colour, and all are charming. There are many more of these newer *Nymphæas*, but the above are a very good set, and contain some of the gems as well as the most vigorous growers of the group. The Irises may be best added as marginal plants, the best kinds being *I. pallida* in variety, *I. pseudo-acorus*, and *I. sibirica* and its variety *I. orientalis*. Many of the *Spiræas* are superb as marginal plants to the pond, and not less so the *Phloxes*, perennial *Asters*, and the brilliant *Berganot* (*Morinda didyma*). In like manner not a few of the hardy *Bimboos* find the margin of the pond a most congenial home. We mention these marginal subjects advisedly, inasmuch as neglect of this item and the omission to plant some of the many suitable subjects only detracts, and that in a great degree, from the general beauty of the scene.]

SOWING WALLFLOWER SEEDS.

THE time has arrived for sowing Wallflowers if a display of sweet-smelling flowers is desired next winter and spring. Some, in their anxiety to get strong plants, sow their seed much too soon, with the result that the plants become too large by winter. There is no advantage in having over-large and vigorous plants by the autumn, for severe weather com-

ing on these succulent Wallflowers often deals hardly with them. Owners of fine plants in early autumn, sometimes find by the spring their display of flower is not in keeping with the autumn prospect. The latter half of May or beginning of June I find to be a suitable time to get in the seeds, and I prefer sowing in the open ground thinly, so that the seedlings can grow sturdily until other vacant ground can be devoted to them. There are several good sorts varying in colour, but the best is a selection of the dark-red and bright yellow. Wallflowers may be had in a mixture of colours from some seedsmen who make a speciality of them. I saw some beds recently filled with Wallflowers in mixture, and I could not help thinking that the person who would not be satisfied with such a wealth of beautiful flowers and wide range of colours must indeed be hard to please. Wallflowers are not difficult to raise, and do not require any special treatment. Soil in fairly good heart, made firm, and in an open position, will supply their wants in this respect. Sowing in drills drawn with a small hoe about 1 foot apart are preferable to broadcast sowing, in that weeds can be more easily dealt with. Should the weather be dry, water the drills before sowing, and continue this until the seedlings have made a good start.

I read the article on the above with great pleasure in your issue of May 3rd. I plant about 3,000 Wallflowers, and I have always found that the second week in June is quite early enough to sow the seed, provided it is not old seed or that the seed is not left to take its chance. When the rows are made in the seed-bed well water them, and then sow the seed half an hour after, and you will find the seedlings will be up in a few days. Many growers allow the seed to take its chance, and if it is a dry season naturally the seed is longer in the ground, and thus a week or two is lost, and in many instances the seed-bed is dug up in disgust, whereas the watering can and a little forethought would have saved the disappointment. With occasional watering you will have good plants for pricking out by the end of July or early in August. Prick them out in rows, say, where early Potatoes have been taken up, but do not give the land any more manure, for if much manure is used the plants will be leggy and sappy instead of dwarf and sturdy. How often do we see them on the top of old walls growing in the most exposed places in the poorest soil, shedding their seed naturally and growing year after year? If pricked out in July, good, sturdy plants and ready for planting will be had by October. If any readers have some very exposed, bleak, draughty situations and are often disappointed with the loss of them during the winter, do not plant until early March or February if the weather should be fine. I am never able to plant until March, for I live close to the sea—in fact, with a southerly wind and high tide the spray comes over on the beds occasionally. When planting I never fill up the hole made by the trowel until I give each plant a little water before pressing the soil to the plant, and by watering the beds occasionally for the first week or ten days I rarely lose a plant. I prefer plants about 9 inches or 10 inches high. Never plant direct from a seed-bed. If possible, find time to prick out, for it makes the plants branch out, and they are more compact and better able to stand the winter. I am afraid many of the disappointments in the culture of this plant follow planting in too rich soil, which makes the plants so sappy that they cannot stand the winter.

T. B., Bridlington.

MANURING BULBS LEFT IN THE SOIL.

(REPLY TO "M. MAY.")

WE think but little success will attend your efforts in the case of the Hyacinths you purpose leaving in the ground, for these do not perfect flower spikes in the same way or time as do the Narcissi. A small spike may be given next year of the former, but hardly a representative one. The Narcissi are different, and improve both in flowering and stature by being left alone. For these take of the phosphate of lime and kainit equal parts, and to these, as

they lie in bulk and together, add nitrate of soda at the rate of one fourth—that is to say, you may use $\frac{1}{4}$ lb. each of the first two, and a $\frac{1}{2}$ lb. of the last. Mix these together thoroughly, and then add of finely sifted loam a $\frac{1}{2}$ peck, or in this proportion to any amount you require. When these are again all thoroughly mixed, the mixture may be applied to the surface of the bed at the rate of two handfuls to each yard super. Avoid the foliage in the application, and finally prick it in with a small handfork or stick, or gently water it home. If your beds are high in the centre, by all means prick in the mixture under the surface, or much will be lost by running down to the sides. Apply at once, and again three weeks hence. In October, and once each month till the end of February, apply guano in solution. Take 4 oz. and dissolve well in a small quantity of water, finally adding water to the extent of 3 gallons for each 4 oz., and with this water the beds containing the bulbs. Three gallons would be sufficient for a square yard, therefore the best way in dealing with it would be each month to mix the required quantity in a tub and apply it at leisure. Liquid manure, if available, diluted with two-thirds water may be employed in lieu of the above, and, diluted as suggested, may be applied freely in autumn and winter.

NOTES AND REPLIES.

Raising hardy plants.—If it is proposed to increase the stock of herbaceous plants from seed, boxes cleared of summer bedding stuff may be prepared for their reception. Sowing in boxes rather than out in the open, allowing the boxes to remain in a cold frame until the seedlings are fairly well advanced, is the better way. One is more certain of a good start in this way, and this is a consideration if seed is both scarce and expensive. The boxes should stand on a good bed of coal-ashes to prevent the ingress of worms.

Hyacinth Grand Maitre.—Of the many blue Hyacinths this is one of the best. In making up a selection of Hyacinths for exhibition or for effective border display, this variety should always be included. Its truss is always large and handsome, and the individual bells are also very fine. I had a dozen bulbs which had been overlooked, and these were not planted until February, and they all flowered splendidly. These late-planted bulbs have this advantage, that they come into bloom quite a fortnight later than the varieties planted at the usual time.—W. V. T.

Old mortar and lime for plants.—Will you kindly tell me what scarlet or yellow plants thrive best in soil which is well mixed with old mortar and lime? My garden is well sheltered, but not very sunny. The soil is fairly good, and has had a top-dressing of the earth mixed with old mortar and lime. I should like to grow Lilies, Tulips, Sweet Peas, Lobelias, Tulips, Anemones, Ranunculus, and Iris, but do not know whether lime suits them.—M. J. K.

[There is nothing named in your list that would object to lime in the proportion named. As a matter of fact, the real lime-hating plants are few indeed—such as Azalea, Rhododendrons, Kalnia, Andromeda, Erica, and the like. In some degree or other lime is present in all loamy soils, and all the Pea-flowering and pod-bearing plants take a large share of it with advantage. Only very recently has it been demonstrated that certain sections of the Iris family are exceedingly partial to it. Asters, Stocks, Iberis, Lupinus, Sweet and other Peas are very partial to it, and with the dressing you appear to have given your garden soil you may grow any Lilies you like, save, perhaps, *L. superbum*, *L. pardalinum*, and the Californian Swamp Lilies generally. Phlox, Lychnis, Carnations, Hepatica, Anemone, Lobelia among red-flowering plants, and Sunflowers, Calceolaria, and others among the yellow. A heavy soil, such as clay, or one retentive of much moisture, as also any soil gorged with manure, is at all times benefited by a free dressing of lime (preferably slacked) in winter. Farmers occasionally give a winter dressing of chalk in lieu of manure. In the garden it is equally helpful. Some of the finest Stocks and Asters (the annual kinds) we have seen were grown in a border that had received a heavy winter dressing of old mortar

in conjunction with trenching, while hitherto in the same border the plants had not been a success.]

THE SPRING CROCUS (C. VERNUS).

The illustration shows how charming the vernal Crocus may be as planted on the Grass. It is reputed to be a native plant, and we have seen the meadows alongside the Leen, and just facing the Castle rock at Nottingham, covered with a soft lilac haze, as its flowers appeared by the million there every spring. These meadows are now built upon, and the Crocusi

so brilliant and variable in colouring. They vary from pure white and softest lilac-blue to the richest stained glass-like purple, and blaze out when the sun shines in the most cheerful way. The common yellow Crocus is one of the most beautiful, and like many other distinct and valuable garden flowers, its origin is lost in the obscurity of the past. It may have been a French or Dutch garden seedling from C. aureus, but proof is wanting. It is, nevertheless, one of the most distinct, effective, and most constant of all the kinds, and ought to be grown by the thousand in all good gardens. The Dutch Crocus will grow in almost all soils,

grown anyhow and almost everywhere—in pots or window-boxes, dibbled along rock-edgings, or even alongside Box-edgings and beside gravel walks, and in sunny nooks and corners near the house, where its corms become well ripened for next year's bloom. F. W. B.

GARDEN PESTS AND FRIENDS.

The tiger-moth (Miss Andrews).—The hairy grub is the caterpillar of the tiger-moth (*Arctia caja*), a very common insect. The caterpillars are popularly known as woolly bears, on account of their long hairs. They feed on the leaves of Lime and Apple-trees, and on various plants, but they are seldom so abundant as to cause any appreciable injury to the trees, etc., on which they feed.—G. S. S.

Fly in cinder path.—Kindly tell me the name of the fly, which appears yearly in April, coming up through a cinder path and raising a little heap of soil like a worm-cast?—MISS ANDREWS.

[The fly is a specimen of one of the many kinds of little bees which make their nests in dry banks, paths, etc. Its name is *Andrena cinerea*. They are perfectly harmless in every way. They store their cells with honey and pollen as food for their future grubs.—G. S. S.]

Insects on Rose-tree.—Will you kindly inform me what the insect is I am sending you herewith? I found it last Saturday on a recently planted Rose-tree when cutting off the dead limbs. Are they destructive to same?—JAMES SCOTT.

[The insect you found on your Rose-tree is the caterpillar of the swallow-tail moth (*Onraptyx sambucarin*). Though a common insect, it is seldom, if ever, that it occurs in sufficient numbers to do much harm. The caterpillar feeds on the leaves, and if several were on one limb they would render the foliage unsightly. I should destroy those I could find.—G. S. S.]

Insects in garden.—Please inform me what the common insects are, how they come, and how to exterminate them, if possible? Are they injurious in a garden? They appear in millions—sometimes a patch about 1 foot square and 1 inch deep, near a garden gate—and though swarms have been killed with paraffin they still reappear. They first appeared, though possibly in no way connected therewith, after the Ivy was clipped.—LOWMEAD.

[The little insects you sent are specimens of one of the many species of Poluride or Spring-tails; they are at times, no doubt, injurious. The clipping of the Ivy cannot, I think, have had to do with their appearance; soaking the soil where they appear with boiling water would probably kill them and their eggs. Lime-water might have the same effect, or a strong solution of nitrate of soda. These Spring-tails sometimes appear in Cucumber-frames, and are the cause of much injury to the plants and fruit.—G. S. S.]

Wireworms in Tomatoes.—Will you kindly tell me what these worms are? I find them get into the Tomato stems and ruin the plants.—W. W.

[The worms that are injuring the roots of your Tomatoes are one of the species of wireworms (*Agriotes lineatus*). It is quite useless to try and get rid of them by the aid of any insecticide, as from their position at the roots of the plants it would be impossible to use any of sufficient strength to kill them without destroying the plants at the same time. You might trap them by burying slices of Potatoes, Turnips, Carrots, or pieces of oil-cake, about 1 inch below the surface, having stuck a small woollen skewer into each, so that they may be easily found. These baits should be examined every morning. I presume your plants are under glass, in which case great care should be taken before the plants are set out to look the soil well over, so as to be quite sure that there are no wireworms in it.—G. S. S.]

Cluster Cup fungus on Anemones.—I sent some of enclosed diseased leaves of Anemone St. Bridget to a scientific man, who says they are infested with one of the Cluster Cup fungi, but he did not tell me what produced it, nor how I could guard against it in future. I shall be much obliged for instructions in GARDENING ILLUSTRATED.—J. G., *Winklesham*.

[Your Anemones are attacked by the Anemone Cluster Cup fungus (*Æcidium punctatum*). The fungus infests the cells within the leaf, the spore-bearing part of the fungus bursting through the skin of the leaves, so that the spores which the little cluster cups contain may be distributed by the action of the wind, insects, etc. The plants that are badly attacked should be at once pulled up and burned; in fact, it would be better to treat all that show any signs of being infested in the same way, and to grow your Anemones in another place for the garden next season. It

Crocus vernus in the Grass. From a photograph by Miss Willmott.

breadths of to-day are much further afield than they were thirty years or so ago. Crocus vernus is one of the hardiest and also the most variable of all the species, and with the nearly related *C. versicolor* has given rise to most of the Dutch or garden seedlings now so popular. The Crocus as grown in Lincolnshire or in Holland is one of the cheapest and most beautiful of all early garden flowers, and its roots are sold at a few shillings a thousand everywhere, and may be planted in the Grass of lawn or home meadow, orchards, and paddocks, or in any thick or sunny along rock-edgings or near the house with advantage. No bulbs produce flowers at once so early and

preferring, however, warm, moist, sunny, or gravelly loams, and some indication of its liking these is shown by its often appearing in gravel walks or amongst old Box-edgings. As used along with Snowdrops, Anemones (such as *A. blanda* and *A. nemorosa*), Bluebells, and Narcissi on outlying portions of the lawn or under deciduous trees, the Crocus is most effective. Visitors to Regent's Park or to Kew will have observed how exquisite its translucent cups can be in the spring sunshine, and as planted on Grass the flowers endure fresh and fair much longer than on bare, wind-swept or rain-splashed beds and borders. The Crocus is so cheap and unchangeable that it can be

might be worth while to pick off the infested leaves of plants that are only slightly attacked, and then spray the plants three times at intervals of ten days with Bordeaux-mixture.—G. S. S.]

Fungus on Pine-tree.—I shall be greatly obliged if you can give me any information re the enclosed. It is part of a growth about 2 feet high which is growing on a branch of *Picea Pinsapo*. I cannot say how long it has been growing, as I only noticed it a few weeks since. The growth appears as a part of the branch it is growing on.—S. C.

[Your *Picea Pinsapo* is attacked by *Peridermium coruscans*, a very common fungus on the Spruce throughout Northern Europe. These somewhat cone-like growths are eaten in Sweden, where they are known as *Mjolkomlor*. The best remedy is to cut off the affected shoots or branches well below the infested parts and burn them, as the mycelium or spawn of the fungus is within the shoots. It is of no use trying to kill the fungus with fungicides, though spraying the trees at once with Bordeaux-mixture might prevent the spores, which will soon be given forth, from infesting other branches. Spray three times at intervals of ten days.—G. S. S.]

Chrysanthemum fungus.—The leaves sent are attacked with some fungoid growth. What is its nature, and how shall I best get rid of it? It occurs only on plants bought from a large grower; my own plants are free.—W. R. M.

[The leaves are affected with a disease known as the *Chrysanthemum rust*, and you are doing the very best thing possible by picking them off. It is usually the lower leaves of the plants that take the rust at this time of the year; therefore, they can be spared without serious injury. We do not favour washing, because to kill the rust one must use something strong enough to destroy the leaves. We saw a case in point to-day where the foliage of finely-grown plants was burned by a strong dose of fungoid wash, and this under the supervision of a skilful grower. Pick off the leaves and burn them is the best advice that can be given.]

The oil-beetle (*Meloe proscarbeus*) (*Meloe Andrews*).—The beetle is a specimen of the oil-beetle (*Meloe proscarbeus*), a common insect, but never found in any numbers together. They feed on the leaves of various wild flowers. Their life history is a very interesting one. The female lays her eggs in the ground, from which are hatched very small, active, yellow larvae, which make their way on to the blossoms of various composite plants. They then attach themselves to any hairy insect that may visit the flower, but only those that are fortunate enough to have taken hold of a small bee belonging to the genus *Anthophora* ever come to maturity. These fortunate ones are carried into the nests of the bees, and feed on the bees' eggs. When they are consumed the larva moults, and appear as fat, inactive grubs, which feed on the honey stored up by the bees as food for their grubs. When it is all devoured the grubs become chrysalides, from which the next spring the beetles emerge.—G. S. S.

The winter-moth.—Will you please tell me the name of the enclosed caterpillars and the means of destroying them? The two large ones are from a wingless moth that I caught in an Apple-tree. I have not seen any of the caterpillars in the trees as yet. There is a quantity of the small ones. I came here last July, and there was not a whole leaf on the trees, and the fruit crop was a complete failure. I put grease bands round the trees early in November. I scraped them and had the thick wood washed with an insecticide. I am afraid they are going to be as bad this year. The trees are half-standards and pyramids.—Z. A.

[The large caterpillars you sent are those of the pale-brindled beauty-moth (*Pligialia pilosaria*); the small ones are the caterpillars of the winter-moth (*Cheimatobia brumata*). I cannot quite understand your letter, as you say that "the two large ones are from a wingless moth that you caught in an Apple-tree, but that you have not seen any of the caterpillars in the trees." Where then did you get them from? Do you mean to say that they were hatched from eggs laid by a wingless moth? Your Apple-trees were doubtless attacked last year, as they are this, by the caterpillars of the winter-moth. You did quite right in putting grease-bands round the trees, but they should have been put on not later than the middle of October, and kept in good sticky condition for at least two months. Care should be taken that they are so tied round the stems that the

moths cannot possibly creep underneath them, and if the tree is supported in any way the supports must be treated in the same manner. However, in spite of all care, some will probably manage to gain access to the buds, where they will lay their eggs. This has evidently been the case, for there are the young caterpillars now on the leaves, and the best thing you can do is to spray the leaves with "Paris-green," or paraffin emulsion. To use the former, mix 1 oz. of the "Paris-green," which you should buy as a paste, in 20 gallons of water, and add twice as much fresh lime as there is paraffin, bulk for bulk, then spray the trees with a garden-engine or spraying-machine with a proper spraying nozzle. Do not drench the trees so that they drip, but so as to just wet the leaves. Be sure and keep the mixture well stirred, as the "Paris-green" is very heavy and soon sinks to the bottom. When this is the case part of the mixture will be too strong and injure the foliage, and part will not be strong enough and the caterpillars will not be killed. The spraying should be done as soon as the fruit has set, and repeated occasionally as long as there are any caterpillars left. As this mixture is very poisonous it must not be used within a month of the fruit being gathered.—G. S. S.]

ROSES.

NOTES AND REPLIES.

Pruning Marechal Niel Roses.—I have been a Marechal Niel Rose, two years old, which has never been cut, but has covered the whole of the root in a very small greenhouse. The wood is very thin, but it has flowered abundantly this year. What shall I do with it now? I do not mind losing the autumn blooms. It has good stuff put to the roots.—E. F. COOPER.

[Unless you at once prune your Marechal Niel Rose quite hard back you will have very weak breaks and poor flowers next year. Autumn blooming with this variety is too rare to be worthy of a moment's consideration. To treat this Rose properly, the lowering branches should be cut hard back the moment the bloom is over. By that we mean not merely the flower shoots, but the long, hard, wooded branches which bore them. Then, from the bases of those below where cut back to, other shoots break out, and the strongest only should be retained, the rest being removed. If the Rose be on a strong-growing stock, and the roots have ample room, and are, during the summer, well fed with liquid manure, shoots varying from 6 feet to 10 feet should result. If pruning be not done now the Rose will become a mat of growth, and a great quantity will have to be cut away in the autumn. That would be so much waste. The stronger the growths made after pruning now, the finer next year's bloom.]

Rose Climbing Niphotos in conservatory.—I have a Niphotos Rose in my conservatory in a pot, potted up eighteen months ago. It has made two shoots about 18 feet in length, and is now flowering well. I shall be much obliged if through your columns you will advise me as to its treatment after flowering.—DILLY.

[Should there be space available for these two long growths to extend, the best plan would be to allow them to do so, otherwise cut them back after flowering to about half their present length. The laterals that are now producing the blossoms should be cut back to two or three eyes whether you curtail the main growths or not. This fine climber seems to require room for extension, and in order to provide it with such space it is best to plant so that its growths run from one end of the house to the other, the border being at the north end. Many laterals will be produced annually on these long growths, and they must be thinned where there is a danger of overcrowding. Many of the splendid vigorous climbing Roses, such as *Sollaterre*, *Climbing Devoniensis*, *Louargue*, etc., if grown on this plan give much satisfaction. When the main growths exhibit signs of exhaustion, one of them must be cut hard back, but only one should be so pruned in a season, retaining the others to their full length until the next or following year.]

Climbing Roses for cold-house.—I propose in the fall transplanting from pots in my hot-house to my cold greenhouse two Marechal Niel Roses. What other climbing Roses would be suitable for the cold-house, which is a lean-to 40 feet long, the wall 12 feet high, the whole length of which is a 6-foot bed, then a 3-foot path, and finally 2-foot benches, all three-bedded.

bench—running the whole length of the house? I wish to have the wall covered throughout with Roses, if possible, and of course good ones. Although a cold-house, it is very hot in the summer, being on a south aspect.—NAVA.

[As you require a few climbing Roses of good quality in addition to Marechal Niel, we should advise you to plant Climbing Niphotos, Climbing Kaiserin Augusta Victoria, Climbing Belle Siebrecht, Monsieur Besir, Bouquet d'Or, Mme. Moreau, and Climbing Devoniensis. The last is rather shy blooming at first, but it is such a lovely Rose that one can afford to wait until its growths have produced some well-ripened laterals, upon which it appears to produce the most blossom. Although this is a cold-house, you will have the advantage of your genial climate during the spring and summer. Climbing Roses of the above description should be encouraged to produce plenty of young wood, so that after the first blossoming much of the old wood that has flowered may be cut away and the new wood laid in its place. We presume your intentions are to prepare a good border for the Roses before planting in the fall. If your garden is pretty well drained you will not require to concern yourself much about the drainage of the border, otherwise it is well to provide Tea-Roses with an efficient outlet for water. A depth of 2 feet of good pasture loam, with one part out of three of well-rotted manure and about 1 pint of bone-meal to each bushel of soil, will provide the Roses with some good lasting material to feed upon. Whilst the climbers are filling out their allotted space you could very well plant one of the less vigorous Tea-Roses between each pair of climbers. Such Roses as *Souvenir d'un Ami*, *Perle des Jardins*, *Bridesmaid*, *Niphotos*, *Mme. Hoste*, *Anna Olivier*, *White Maman Cochet*, *Maman Cochet*, and *Mme. Lambard* would be first-rate kinds, and would give you two or three crops of blossom each season.]

The weather and the Roses.—The cruel spring frosts have already visited some localities. We had the week before last quite 8 degrees, and it was pitiful to see the blackened growths. I would advise the Rose-grower not to be in a hurry to cut away shoots. It is marvellous how they seem to recover, and, provided the buds be not visible, often no injury follows. Last season I almost determined to cut off some shoots of a Rose that had been badly frosted, so much so that the growths were quite drooping, but they were suffered to remain, and I could not see any difference at time of flowering from these and other plants more fortunately situated.

FERNS.

Selaginella failing.—Can you tell me the cause of the enclosed plant dying off like the piece I have sent you? Last year it appeared very healthy, and covered profusely a large piece of rock-work in a conservatory (the heated). It has been growing there for several years, but now all the long pieces turn brown, and only leave a little piece of green just at the end. Is it possible it could be injured by any insect? It is well watered.—A. C. K.

[The soil is exhausted. You ought to have broken it up and replanted it every year, adding at the same time some fresh material for it to root into.]

A hardy fernery.—I have been much interested by an article which appeared in *GARDENING ILLUSTRATED* for May 3rd, and written by M. S. KNOX-GORR, on hardy Ferns, etc. I am also very fond of Ferns, and have a fernery under glass, but with no artificial heat. I would feel obliged if "M. S. K." would kindly say if the fernery is under glass and unheated? The writer also talks of growing double *Primroses* with the Ferns. I would be glad to know if the plants are strong and robust, and not delicate-looking grown in such a shady place.—W. SOUTHPORT.

[The hardy fernery mentioned in the number of *GARDENING ILLUSTRATED* for May 3rd is not under glass, but in a sheltered position on the edge of a wood. The double white and mauve *Primroses* are grown amongst the Ferns, but not shaded by them. I fear they would not flourish equally well under glass unless grown in a cold-frame or ordinary cool conservatory. In this latter I have successfully grown the blue *Primroses*, *Primula casuarinensis*, and the ordinary Alpine *Aureicula*.—(Mrs.) M. S. KNOX-GORR, Belleek Manor.]

As many of the most interesting notes and articles in "GARDENING" from the very beginning have come from its readers, we offer each week a copy of the latest edition of either "STOCK AND GREENHOUSE PLANTS" or "THE ENGLISH FLOWERING GRASSES" to the reader of the most useful or interesting letter or short article published in the current week's issue, which will be marked thus:—

INDOOR PLANTS.

A NATURALLY-GROWN AZALEA.

The plant of Azalea we figure to-day has been allowed to grow in a thoroughly natural way, hence we get the shoots loaded with bloom. How much more beautiful is an untrained Azalea than the hard, stiffly trained plants one often sees at exhibitions. There used to be in the R. H. S. Gardens at Chiswick a plant of the old *A. indica alba* quite 8 feet high and as much in diameter, which when in full bloom was always admired. This was grown in an entirely natural way, and every year was a mass of bloom. To compare such a plant as this with the closely trained pyramids and flat bushes generally found in the exhibition tent is absurd, so much more beautiful was it. You may often hear it said that unless Azaleas are trained they will not travel. No doubt the branches require a little steadying, but with the aid of a few sticks and a little Ralpin they can be sent a few miles without being trained in a manner that makes them little short of hideous. The appearance of plants naturally grown is ample proof that the practice is a

plants are more attractive than the tricolor Pelargoniums brought into Covent Garden Market by those who make a speciality of them. The great point is to strike them early in August, keeping them just on the move up to the turn of the year, then potting them off and giving just enough heat to ensure a free leaf growth. The soil used for the ordinary Pelargoniums will suit them, adding, perhaps, a little more silver sand. Fuchsias require the same treatment as the ordinary kinds.]

Dipping cut flowers in warm water.—In sending away Violets, Gardenias, or St-paulias, would dipping them in warm water after gathering be a good thing? I find even here in the house they wither the next day after they are gathered.—P. H. L.

[Flowers of almost any kind are the better for having their stems placed in water for a time prior to sending by post or rail. This is especially the case in warm weather, when evaporation is so rapid. Warm water is not necessary, indeed, often it is injurious to gathered flowers. An important matter in connection with the use of flowers, whether for home or sending away, is to see they do not flag before they are stowed in water. The flowers you name certainly ought not to wither the day after being cut, but some dwelling rooms

Russelias we know there is a strong family likeness, and a brief description of the old and well-known *Russelia juncea* will suffice for the whole of them. It is a very beautiful and distinct plant, the branches being slender and Rush-like, while the tiny leaves are but sparingly produced. This latter feature is not, however, particularly noticeable, owing to the bright green of the slender pendulous shoots, which hang down for a considerable distance. The flowers, which are borne in considerable profusion during the summer months, are each about 1 inch in length, tubular in shape, and of a bright scarlet colour. *Russelia juncea* has a very pretty effect when trained to a rafter in a small structure, as it is not sufficiently vigorous for a large house. Grown in this way the bright pendent, Rush-like shoots form quite a fringe, and when lit up with the numerous bright-colored blossoms it is, of course, additionally attractive. In suspended baskets, too, its distinctive features are well shown. It also forms an effective specimen if the principal branches are staked upright and the minor shoots allowed to dispose themselves at will. Equal parts of loam and leaf-mould or peat, with a good dash of sand, will suit this *Russelia* well. Good drainage, with a liberal amount of water during the growing season, is also required. For its successful culture the temperature of a stove, or, at all events, of an intermediate-house, is necessary. There is no English or popular name for the *Russelias*.]

Heliotrope in winter.—Please tell me how I can most successfully train a *Heliotrope* to grow up the wall of my conservatory? It is a cold house, the normal temperature night and day in winter being not lower than 45 degs. Would it be possible to make the plant flower through the winter, and, if so, how? I have just repotted a *Heliotrope* a foot high. There is plenty of leaves on the top of the plant, otherwise the stems are rather bare and "lanky" looking.—BRUNNEN.

[In order to train a *Heliotrope* up the conservatory wall a very necessary item is a good vigorous plant to start with. You say that your plant has plenty of leaves on the top, hence we should conclude that it is in good condition, and having been repotted, it will, in all probability, grow away freely. The leading shoot should be secured to a good stake, as the main object is to get it to mount upward. When required it must be shifted into a larger pot, and finally, if possible, planted out, as the *Heliotrope* will, after its juvenile stage is past, make more rapid progress when planted out in a prepared border than if confined in a pot. Still, next spring will be soon enough to plant yours out, as then you may reasonably expect it to go ahead rapidly. In preparing a border for planting it, thorough drainage must be ensured, as stagnant moisture, particularly during winter, is very injurious to the *Heliotrope*. We cannot hold out much hope of your *Heliotrope* flowering during the winter, as to do this successfully a temperature from 10 degs. to 15 degs. higher than that mentioned by you will be needed. Still, the temperature named should keep it in good condition throughout the winter season, and with the return of spring it will grow away freely and soon flower. When planted out, the shoots as they develop must, of course, be trained to the wall. One caution to be particularly observed in the cultivation of the *Heliotrope* is, should aphids or green-fly be troublesome, not to fumigate, as that will destroy most of the leaves. The XL vaporiser may, however, be used with perfect safety.]

Green-fly on Roses, Pelargoniums, etc.—In the spring months most cultivators are troubled with this pest to a greater or less extent. To keep it under is of great importance, and many things are used to this end. Fumigating is most commonly recommended, but many dislike this in any way, as it is not everyone that can endure this. Some years ago I used a lot of fumigating material, but during the last few years I have almost given it up, having proved that dipping, spraying, etc., are far more satisfactory. Many washes can be obtained, all more or less good. Years ago I made my own wash, but have given it up, seeing I can buy it more cheaply than I can make it. I make it a rule not to allow things to get infested with insects; immediately I see their coming I begin spraying or dipping. *Cyperias* can easily be kept clean by spraying once a week. The same may be

A naturally grown Azalea. From a photograph by Mr. James E. Tyler, Halstead, Essex.

commendable one, without taking into consideration the amount of labour, time, and material saved. T.

NOTES AND REPLIES.

Celsia Arcturus.—G. M. Sanders, Lincoln, will find a short article on above plant in *GARDENING ILLUSTRATED* for May 3rd—though *Celsia cratica* is mentioned instead of *Arcturus*—which no doubt will help him in the matter. I have not found old plants so good as seedlings, the latter making much stronger plants.—J. M. B.

Tricolor Pelargoniums.—What treatment is best for foliage Pelargoniums and Fuchsias in pots in the greenhouse? Should they be kept in poor soil with little water to preserve the colouring, and may they have manure or not.—ASOX.

We are supposing this is what you mean by "foliage" Pelargoniums. The beautiful shades of colour that one so much admires in the tricolor Pelargoniums are never so distinct as in the early spring months. This section requires in a temperate climate, such as it is easy to create in the early spring months. Given full sunlight and an average temperature of 50 degs. by night and 55 degs. to 60 degs. by day, whilst not deprived of too much air and supplied with sufficient atmospheric moisture to promote a free and luxuriant growth, the various colours which are found united in the leaves become bright and distinct. Few

are predisposed to this failing. We have known instances where flowers gathered at the same time have been arranged in vases and placed in two separate rooms—the one kept cool, the other conveniently warm. In one the flowers will endure not more than three days, sometimes not even that time, fresh; in the other, flowers will remain a whole week with a change of water, and sometimes longer. Of course, gas is fatal to long life in plants or flowers placed in living rooms at any time. A small room in one house is better than a large one in another sometimes, so that short life in flowers cannot always be charged to polluted air. Cut flowers should be kept as far away from a room fire as possible, and exposure to sunshine in a cut state is not good for them. Try stanching them in a cool place in water for a few hours before arranging your flowers in the house.]

Russelia grandiflora.—I cannot trace this in any British catalogue, but it is given in an American one. Please give English name, also culture.—H. LEDGARD.

[*Russelia grandiflora* is quite unknown to us, and we cannot find it mentioned in any works of reference at our command. Such high-sounding names are favourites with some of our readers, and we should say that this has been given for trade purposes. In all the

said of Pelargoniums and things akin to them. For the last four years I have used Abol insecticide with the best results.—J. Crock.

TREES AND SHRUBS.

CARPENTERIA CALIFORNICA.

This noble shrub has now fully established its reputation for both indoor and outdoor culture. It does well against the back wall of a greenhouse, the flowers being at their best in the third week of April. Buses against walls generally begin to flower about the beginning of July. It is quite hardy in the south of England. The flowers are pure white, about 3 inches across, with a bold group of stamens of a lively yellow. The foliage is also handsome. It thrives best in a sandy loam well drained.

NOTES AND REPLIES.

Honeysuckle in pots.—It is seldom that one meets with this deliciously-scented climbing shrub in pots for conservatory decoration, but it certainly well repays the little trouble it takes to do so. One of the best varieties I have ever grown for this purpose is the old favourite Dutch variety that makes good plants of dwarf, sturdy habit. Pot up in the autumn good strong plants of two or three years' growth in 8-inch pots, and plunge them in a bed of leaves, and at this time of year bring a few under glass at a time, so that they may give a long succession of bloom. If the young growths are piped at about 1 foot long, they may be kept in pots for several years. Fumigating to keep them clear of green or black-fly is the main thing needed, as also plenty of water at the root.—J. G., Gosport.

Thuja Lobbi as a hedge plant.—With the exception of the Holly, there is nothing so good as the above for forming hedges and screens. It makes rapid growth when planted in well-prepared land, so that a hedge 10 feet high and well furnished from top to bottom may be had in five years if good, bushy plants about 18 inches high are used. This Thuja, like the Arbor-vitæ, bears clipping well, but has the advantage of retaining its verdure all through the winter; no matter how hard the frost the rich hue of the foliage remains unchanged. *Cupressus Lawsoni* should not be used for this purpose; it does not bear hard cutting in, and in the course of time the base of the hedge gets brown and ugly gaps occur.—J. C., Byfleet.

The flowering Currant (Ribes).—I note your remarks about the beauty of these spring-flowering plants, and agree with you that more of them ought to be found in our gardens. I have them in many varieties, massed in a large bed, where each one shows itself to the best advantage, and is at its best about the middle of April. They thrive in any good garden soil, and enjoy a little leaf-soil with loam when replanting. Though not so robust as the common variety, most of these better kinds should be trimmed into shape a bit after passing out of flower, as young wood made and ripened the previous year carries much finer flowers than does short stubby wood. If manure-water could be given them occasionally at the end of May and during June, the plants would make much more satisfactory growth, and would well repay the labour bestowed on them by the amount of bloom produced the following season. A sunny aspect should be given them, but avoid too dry a position if possible. My collection consists of *albium*, *anroum*, a *præcox*, *saxatile*, *nigrum*, *diacantha*, *triste*, *sanguineum*, and *missouriense* (syn. *lorinum*). The foliage of the last is conspicuous in autumn, when it assumes a purplish-brown. It is easily

easily propagated by cuttings in autumn or layering about the same time. The old form should be cut hard back after flowering, when new growths, each 4 feet to 6 feet long, will be very beautifully in bloom within a year. There appears to be more than one variety of this, as I have a very large bush in the shrubbery here much more washy in colour than the rest. It may have been a chance seedling.—J. M. B.

VEGETABLES.

EARLY CABBAGE.

In the varieties of early Cabbage we have made considerable progress, and this without loss of flavour, though the size is diminished. This is a gain to the private grower, as a small Cabbage is much nicer for the table than a large coarse one. I always advise early sowing, as a good breadth of Cabbage to follow the winter green vegetables is more serviceable than later. There is considerable gain in making two sowings; one can afford to lose a few from rotting if Cabbages can be cut a month earlier than

sturdy growth. By using a dwarf Cabbage, such as *Ellam's*, there is less need of large quantities of manure, as these small kinds do not root deeply like coarser kinds, and are a shorter time on the ground; there is much gain by growing such varieties, as they may be planted closely and they never look patchy. A succession is readily secured by sowing in three weeks after the first sowing, and to succeed these a pinch of seed sown in a little warmth early in the year will give a succession of Cabbage as long as it is required. I would also point out the advantage of sowing three or four times a year, getting nice tender heads in preference to allowing the old stumps to remain after cutting, as they rob the ground and harbour grubs and caterpillars. G.

MOULDING UP POTATOES.

The exigencies of the season have led to a good deal of moulting up of early outdoor Potatoes already, because cold nights and white frosts have rendered some covering of the tender leaf-tops necessary. It may well become matter for discussion whether much is gained by planting

Carpenteria californica in Col. Baskerville's garden at Crowsley Park, Henley-on-Thames. From a photograph by Mr. Thomas Taylor.

would be the case if sown later. I have seen Cabbages sown so late in August that it was impossible the plants could stand the winter. Some people may say that early sowing is conducive to halting. It certainly is with some varieties; hence the necessity of selecting a reliable kind. From several years' experience I have found none equal to *Ellam's Dwarf Early Spring*. *Ellam's* also possesses another good quality—hardiness, a great point in winter Cabbage, as out of many hundreds there is scarcely a gap in the rows. I attribute this hardiness to its dwarf compact habit, as if well moulded up in the early winter there is but a small portion of the plant exposed, the erect growth throwing off excessive moisture. It may be thought any variety may be so treated, but the growth differs. Many kinds have a spreading habit and longer stem, and are, therefore, more exposed. By sowing as advised and planting as soon as really on deeply cultivated ground, there need be little anxiety as to this variety turning in when required. The seed is sown from July 15th to 20th, and there is little fear of rotting. I like to make light firm before planting, this is necessary

seed-tubers so early, and necessarily in cold ground, so as to cause them to have tops above the surface from the end of April. If frosts do not catch them and inflict material injury certainly the cold soil and air check growth and it becomes very doubtful whether well sprouted seed-tubers of similar early varieties planted a month later do not in the end give quite as early, if not indeed better crops. In any case, covering up the growths with soil though but thinly, to protect them from late frosts has become a necessity, although under ordinary conditions moulting up would follow later. But as a matter of culture moulting up is invariably done, yet not always well or properly. One of the worst evils incidental to bad work is the covering up of so much of the lower leafage. That is slovenly work. Were more care shown by employing two persons to do the moulting, one should be instructed to use a long rod wherewith to lift the lower leafage from the ground, that loose soil between the rows may be drawn up close to the stems of the plants without injuring or burying the leaves. Not only does this burying of leafage help, as it were, to tie or hold down the plant

growth, but it rots the plants of much reproductive power, as tubers are, after all, the primary products of leaf action.

It is, indeed, a question whether moulting up of Potato plants, by which much leafage is buried or injured, compensates for the labour or for any advantages that may result from the labour. That proper moulting up does reader Potatoes good service there can be no doubt. Thus, it is important that the tubers be well secluded from air, otherwise they become hot and astringent. That may be of no moment in the case of seed tubers, but as Potatoes are primarily grown for eating, such exclusion of air is of great importance. Then a proper moulting up gives the plants needed support in windy weather, and prevents much twisting and injury to the stems. But, not least, it is now fully understood that a good moulting up, or coat of finely pulverised soil, over the newly forming tubers greatly helps to exclude fungoid spores from them, thus saving them from disease. Generally the advantages which result from proper moulting much outweigh the cost of labour involved in the work of moulting. But to do it properly, Potatoes should be far less crowded than they habitually are, for crowding, whilst causing waste in seed tubers, never does produce such fine crops as thinning planting does. Also, prior to the work being done, the intervening soil should be either deeply hoed or lightly forked over.

A. D.

SOWING ASPARAGUS SEEDS.

The facility with which young Asparagus plants can be obtained at a very reasonable price is the cause why so few sow this seed nowadays, as they thereby avail having to wait two years for plants that they can buy for six or seven shillings the 100. In large market gardens, however, and in the case of important trade houses, the purchase of the plants in great quantities would be too costly, and the cultivators who can afford to wait will be well advised to raise the plants they want from seed. Asparagus, it is well known, does best in light, warm, and sandy soil; it should be sown in soil manured in the autumn, or at least a year previously. The seed of Asparagus should be sown at the end of April or middle of May in lines about 16 inches apart and about 1 inch (a little more or less) deep, the earth being afterwards raked over and trodden down. During the first year hoeing and weeding to keep the soil clean should not be neglected. In the spring following the stems of the Asparagus should be cut and the ground well hoed and weeded. About 11 lb. of the seed will produce 10,000 plants.

JULES RUDOLPH (*Revue Horticole*).

NOTES AND REPLIES.

Asparagus rotting.—I am sending some pieces of Asparagus, and would be greatly obliged if you could tell me the cause of them growing like this. They come up and then wither off. The rows are about seven years old, and they were good last year. Can you suggest any remedy?—M. S. THIBALL.

[The sample of Asparagus heads you sent is indeed a bad one, and in an advanced state of decomposition. But it is impossible for us to say whether this rottenness is due to the soil, or to excessive dampness, or to injury by frost. If you have had sharp frosts following on rain then the appearance of the Asparagus would be explained. If it be not so, and there seems to be no ordinary reason for the injury, then the cause must be in the soil. If that be so, your best course will be to top-dress the bed freely with fresh-slacked lime and just point it in.

If growth after the usual cutting is over be weak, densely dress the beds with soot and wash in with water or any weak liquid manure. A good dressing for the beds would be 2 oz. per square yard of bone-flour and kainit (potash). Perhaps you have used coarse animal manure too freely on the beds.]

Onion bulbs the second year.—I have been told that a good plan to get good Onions is to sow this year on poor ground, where they will grow only to the size of nuts, and when they mature to store for winter, and plant them out in spring. Is the system worth a trial, at what date should they be sown, and will they not run to seed?—J. EXAS.

[The plan you refer to of sowing Onion seed on poor ground one season to produce small bulbs, then wintering them and planting them out on to good soil the following spring, for the

purpose of swelling into large bulbs, is an old one, and now rarely practised. It was recommended to sow at the end of May, as, if sown earlier, the bulbs would the following year bolt off to flower. We can very well understand that such result would often, if not generally, follow even with May or later sowings, and in any case the game is not worth the candle. We have seen splendid bulbs of Ailsa Craig and other fine varieties obtained from an autumn sowing outdoors made end of August or early in September, and in the spring carefully transplanted, the bulbs even beating the Tripolis. But the finest of all Onions now are raised by sowing seed of the varieties just named in shallow pans under glass early in January, growing the plants on cool, then transplanting outdoors into rich, deep soil at the end of April, and 1 foot apart.]

Yellow spot in Tomato leaves.—Will you kindly inform me what is the matter with my Tomato plants, and what to do to prevent it spreading? I have a house with about 300 Tomatoes, planted out, and a number of them have shown a lot of yellowish spots in the leaves. I enclose a few for your inspection. They are planted 2 feet apart, and every attention is paid to watering, ventilation, etc. The house is a very roomy one. I have grown Tomatoes in it for two seasons, but have taken all the soil out to the depth of about 1 foot, burned sulphur in it, lime-washed it out, and replaced with fresh loam each year. As soon as the Tomatoes are done it is filled with plants in pots. I have pulled all the infected plants up so far and burnt them, but as I am afraid that there are others, I am anxious to know what to do to prevent the trouble going through the house.—AMARA P. C.

[The Tomato leaves received were so much bruised in transit that we were able to form but little opinion as to the cause of your complaint. Tomatoes are addicted to so many ailments that there is difficulty in prescribing for them at all or locating the cause. Yours does not appear to us a very serious trouble, and we do not see the need of destroying the plants because of the spots on the leaves. We should pick these portions of the leaves off, and allow the plants to grow and fruit. Errors in ventilation and watering often bring about leaf troubles, especially in such seasons as this. During the prevalence of such cold winds, it is best to maintain a drier atmosphere and give less water than when the weather is more genial. The growth may be slower, but it would be more proof against disease. There are some structures and some soils that foster disease, both of the leaf and fruit, which cannot be in any way accounted for, and yours may be a case of this sort. Ventilation is an item of importance in Tomato culture; if neglected only in a minor degree, trouble in some form will soon assert itself. Never allow the temperature to rise suddenly without ample ventilation. Gentle warmth from the hot-water pipes is a great help in Tomato growth, but it should be regular, or much trouble will be had sooner or later in leaf disease. You have done right in changing the soil, but it is not customary to do this every year. By treading the soil a little deeper each winter, bringing up a little fresh to incorporate with the surface, some growers succeed for several years. Others, again, change the surface soil in alternate years. This course of necessity gives heavier crops, and usually greater freedom from disease, which is only to be expected, considering the labour it involves. Beyond careful and ample ventilation, avoiding extremes of heat and cold, and giving water at suitable intervals, there is nothing we can suggest that you can do at this season to stop the spot from spreading.]

Blanching Seakale.—In a good garden which I recently visited in Dorsetshire, where Seakale is largely grown as an annual product by means of root cuttings, the best of all methods to propagate this useful vegetable, the gardener mentioned that he always reserved a few rows of the roots as grown outdoors all the winter. Then, as the spring drew on, he placed over a portion of the crowns 6 inch drain-pipes, made specially for the purpose, 8 inches long. These were, of course, stood end-wise over the separate crowns. They were then filled with fine soil. In this way most perfect upright blanched heads were obtained, the plan being far better than was heaping up ridges of soil over the crowns. Two or three other rows would be so covered later, and in that way good blanched Kale kept until the latest possible time. Small growers of but a few square feet may adopt that method with

advantage. They can, after the pipes are done with, stand them here and there beside garden walks, burying the bottoms 2 inches in the soil, filling with good soil, and putting in some good flowering plant or a few seeds.—A. D.

GARDEN WORK.

Conservatory.—Fuchsias are lovely now in any form, but especially as tall pyramids trained to a single stake in the centre with the flowering branches drooping gracefully on all sides. A Fuchsia will flower as freely in a young state in a 5-inch pot as when several years old and 6 or more feet high; but for early flowering in small pots the cuttings should be rooted either now or during early summer for early flowering following spring. Spring-struck cuttings make nice little flowering stuff during the summer, but they are not early enough for the market grower. It is the same with early flowers as it is with fruit and vegetables—the first comer realises most. In a large, cool conservatory Fuchsias of the free growing kinds planted out and trained to wires under the rafters are very effective, and I have had them do well planted out and trained to vertical wires rising in any part of the house. The wires are fixed to blocks of wood driven in the borders and secured at the upper end to one of the tie rods, or in some other way. Of course, Fuchsias planted out in the border will bear a good deal of pinching and pruning, but they pay for the trouble, and they flower continuously all the summer and well into the autumn. Scarlet and other Salvias should be rooted now, and when well established in pots and hardened, may either be planted out or grown on in pots. The planting out system produces the largest plants, but do not crowd, and attend to the pinching and watering if necessary during the summer. Arum Lilies may be divided and planted out now if that system is adopted. For early flowering we prefer to grow in pots, but the planted out stuff comes in well for Easter. Of late years the culture of these Lilies has been overdone and the prices have ruled low. The berry-bearing Solanums will be ready for a shift now. If it is intended to plant them out, set them out in a sunny position, giving plenty of room for growth and air circulation. Here, again, for early work it is better to grow a part of the stock in pots. Some of the silver-leaved and other Maples will be in good foliage now if brought on under glass, and will be useful among dark foliaged plants as backgrounds. Calceolarias must be kept free from insects.

Stove.—Moisture in the atmosphere and shade during bright weather should be applied with judgment so that they, as it were, balance each other. Shade should be looked upon as a necessary evil. If excessive shading is used it becomes an evil, as it weakens growth, and if it is necessary at any time to take plants from a much shaded house for any decorative purpose they suffer, and this we want to avoid. Continue to strike cuttings of Poinsettias as the young shoots can be obtained. Strike singly in thumb-pots in sandy peat plunged on a brick bottom. Lift out of the plunging bed as soon as rooted, still keeping close and warm for a short time, and then transfer to larger pots. Afterwards they may be gradually hardened off, keeping them near the glass so that the plants may be dwarf and sturdy. Old plants may be usefully planted out in a bed of peat and loam at the back of a warm-house. We have had them do good work at the back of a low lean-to Melon-house. In such positions the wood ripens up well and the heads of broets are fine for cutting and save the plants grown in pots. The old *Rondeletia speciosa* major is very useful where cut flowers are in demand, for though one cannot cut sheaves of bloom off it, there is generally something to cut from it, and the flowers are always appreciated. Vincas, in the shape of good specimens, generally used to be found in collections of stove and greenhouse plants. They are not difficult to grow. Liquid manure will help them.

Pines.—Keep the atmosphere moist by damping floors and surface of beds. Dew the plants over twice a day with a fine rosed syringe, avoiding all plants in flower and ripe fruits. In hot, bright weather the damping of floors and beds will be supplementary to the

syringe. Ventilate moderately when the thermometer reaches 80 degs. and close early, damping down at the same time. Give liquid-manure to plants which have filled their pots with roots. If the suckers are taken and potted when ready they will come on in succession. Suckers have an exhausting effect on the plants, therefore only a limited number should be permitted to develop. There are generally stated times for a general overhauling of the Pines, and then there are a general repotting of successions and suckers and a renewal of the plunging-beds, but, of course, successions can be potted any time when a shift is required. There is one advantage the Pine grower possesses over other fruit growers, except it may be Grapes. The fruit will keep some time after it is ripe if the pot is lifted out of the house and kept in a cooler structure, of course, giving no water. Nothing spoils the flavour of ripe fruit—whether Pines, Peaches, or Melons—as a heavy deluge of water after the fruit is nearly ripe. Feed freely during the swelling process, but when the aroma of the ripening fruit pervades the atmosphere discontinue watering.

Late Grapes.—May has been a very trying month, especially to Grapes in cold-houses. If fire heat is not used, or used only sparingly, the moisture in the atmosphere must be used sparingly also, or the foliage may suffer. But no one can grow good Grapes under glass in a season like the present without fire heat. Avoid overcrowding the foliage. The bearing shoots should be a foot apart on each side of the main rods. Some allow even more space, but a foot should be taken as the minimum distance. Keep down sub-laterals. With good main leaves they are not required, except as safety-valves for controlling the growing force of very vigorous Vines. Give a little air early in the morning, and increase it gradually as the sun gains power. Keep the border moist, and it is an advantage to take the chill off the water when used from a pump or a cold, exposed tank, but the water can be used from a supply inside the house at any time.

Window gardening.—*Plumbago capensis* is a very useful plant in several forms. It makes a neat little specimen in a 6-inch pot trained over a neat wire trainer, and it flowers in summer when flowers of a distinct type are getting scarce. Of course, now we have an abundance of blossoms in *Pelargoniums* various, including some of the scented-leaved varieties. We appreciate the old Oak-leaved *Geranium*, with its spicy perfume. *Lady Plymouth*, with its neat habit, is a good cottager's plant. *Fuchsias* are coming into bloom. *Musk* is growing rapidly. *Calceolarias* should be grown in a shady window and kept free from insects.

Outdoor garden.—The weather is yet too cold to think of bedding out, as the term is, anything but the plants which have been thoroughly hardened by exposure. To take plants from the greenhouse and plant them in the beds will give a check to growth that will be felt for some time. Of course, such things as *Calceolarias*, *Asters*, and *Stocks* which have been well hardened may go out with safety. Even *Geraniums* which have their leaves hardened by exposure will take no harm. *Heliotropes* and *Zinnias* soon show the effect of frosty winds. The growth of hardy subjects is very backward, but those who have Tufted *Pansies*, *Wallflowers*, and *Doronicums* will have some colour in the borders. The *Scarlet* and other *Thorns* or *May* will hardly be in flower this season before the end of the month, except in warm situations; but *Lilacs* and *Laburnums* are showing colour. Those having a sheltered garden might do more with the hardy *Magnolias*, most of which are very beautiful. The lists of the Continental nurseries are much fuller of names than our own, but their system of grafting everything is a bad one, as its tendency is to shorten life. Especially is this seen in the better kinds of *Broom* (*Genistas*), such as *Audreana* and *precox*. The beautiful double-flowered *Plum* (*Prunus triloba*) when obtained from the Continent is generally worked on a common *Plum* stock, and the work of keeping down suckers is considerable.

Fruit garden.—I have never seen fruit-trees so full of blossoms, taking them all round, as they are this season. The Apple just now

is a picture of floral beauty, but the 10 degs. of frost on the morning of the 14th inst. has had a depressing effect, though the blossoms will bear a good deal of thinning and still leave a crop. As soon as the petals fall the sprayer must be put in operation, as there are sure to be insects, including the larvae of the *Codling-moth*, to deal with. Those who are looking for a site for planting fruit-trees must take into consideration the value of shelter. There will be plenty of object lessons this season if one observes closely. The blossoms of the early *Strawberries* have suffered from the frost. I am told one very large grower in this district has given up growing *Royal Sovereign* because of the loss from spring frosts. If there is any liquid-manure to spare, let the fruit-trees which are in a free-bearing state have it. To have fine fruit the trees must be fed, and surface-feeding is the right course to adopt. In exposed gardens Peach-trees are showing blistered foliage. When the weather settles the worst leaves can be picked off and the trees washed with an insecticide. In the meantime, Tobacco-powder will keep both insects and mildew in check. On warm, south walls the roots of the trees are probably too dry, as the rainfall is below the average.

Vegetable garden.—The frost has given a severe check to the early Potatoes. They will break again, but the value of the crop has been reduced. The hoe and fork, if used freely, will encourage growth. Young crops of Carrots, Parsnips, and Onions should be thinned before the rows become much crowded. It is difficult, perhaps, to rightly gauge the quantity of seeds to secure a sufficient number of plants to give a chance of selection, but in many gardens the seeds are sown much too thickly, and besides the loss of seeds, injury is done before the crops are thinned. It is a good plan to prepare Celery trenches as soon as the green crops can be cleared off, and then Lettuces or something else can be planted on the ridges. Excellent Lettuces are generally produced between the Celery trenches. Sow a few rows of Chicory if not already done, as it comes in useful for salads when forced in winter. Vegetable Marrows and ridge Cucumbers may be planted under haulights, or sheltered in some other way. I have seen them covered by inverting flower pots over them for a few nights till the plants are settled in position. The earliness of any crop adds a value to it. The Turnip-rooted Celery (*Celeriac*) is planted on the surface on well-manured land in rows about 2 feet apart. The plants are raised in the ordinary way. E. HOBLAY.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

June 2nd.—Just planted a good breadth of Brussels Sprouts and a couple of rows of Celery and Leeks, the latter in shallow trenches with a little old manure worked into the bottom. We are growing *Verbenas* again somewhat largely; they make when well managed lovely beds, either in separate colours or as mixture. Continued the spraying of fruit-trees. A determined effort will be made to get rid of insects.

June 3rd.—Onions that were raised in boxes in heat and planted out last month are making rapid progress. This is the right course to adopt with selected stocks, as it saves the seeds, and the transplanted Onions generally do well, and in our case have escaped the maggot. Sowed another box each of *Cineraria* and *Primula* seeds. We are busy hehking out now, and other work for the time being must wait.

June 4th.—Planted out *Dallias*. We are growing chiefly Cactus varieties; they are so useful for cutting. Sweet Peas are growing freely, and will have an occasional soaking of liquid-manure. The loveliest lot of Sweet Peas I remember to have seen was raised in single pots and afterwards transferred to Sea-kale pots, placed bottom upwards alongside a walk, and freely watered with liquid-manure. Creeping Jenny was planted to hang over, and the liquid-manure helped greatly.

June 5th.—Peaches ripening are freely ventilated, and watering the border has ceased for the present. The fruits are looked over daily, and the ripest gathered and placed in fruit

room to complete ripening, or else packed up and sent away. Sir Charles Napier in pots has done well as a late crop. This is an old favourite, and takes some beating. Planted out Tomatoes against walls and fences. Some will be planted out quite in the open and trained to stakes.

June 6th.—Fig-house, where the fruits are ripening, is kept drier, and syringing discontinued for the present. Figs and Vines on south wall are often looked over and young shoots thinned, but outdoor Figs are never stopped, as only one crop can be obtained. Even in a cold house the second crop seldom ripens. Planted several rows of the white-seeded *Scarlet Runner Beans* for late bearing. Insects on Roses are having a lively time. No quarter is given.

June 7th.—Violets preparing for winter flowering have been hoed through, and a mulch of old Mushroom-manure laid between the rows to save watering and encourage growth. Some large specimens of *Dielytra spectabilis* are making a lovely group in a cool-house. Long sprays are good for cutting, and look charming in a tall vase. Sowed more Lettuces of various kinds. Continuity is a good Cabbage Lettuce for dry soils and seasons.

BEES.

SEASONABLE WORK IN THE APIARY.

The most interesting period in the Bee-keeper's calendar is now at hand in the increase of colonies by natural swarming, although much depends upon locality, the state of the weather, and the conditions under which stocks were wintered. Where hives are well filled with Bees in autumn, in addition to being well provisioned, they are ready to swarm some weeks sooner than if left weak in population and short of stores. In spring, when a hive has become very crowded and stores are coming in plentifully, the queen commences laying eggs in drone cells and the workers construct queen-cells. In the latter, eggs are deposited about four days before a swarm issues. Where frame-hives are used the queen-cells may be easily discovered if the central frames of comb are examined and search made along the edges of the combs. The queen-cells very much resemble an Acorn in shape. Should one or more be found to be cupped over it may be concluded that, weather permitting, a swarm will shortly issue from the hive. If, however, the state of the weather prevents a swarm leaving a hive at the right time, the queens in embryo are destroyed and the swarming delayed till queen-cells are again prepared.

The chief indications of swarming being about to take place are the crowding of the Bees at the entrance of the hive, general restlessness, and the appearance of drones. Swarming usually takes place between ten in the morning and four in the afternoon. If on a fine morning for honey gathering but few Bees are seen at work, while on the previous day all was activity and excitement, a swarm will be pretty sure to issue in the course of the day. In the act of swarming the Bees pour out of the hive in a constant stream, and all, apparently, wild confusion; they, however, soon begin to collect at one spot—generally some bush or tree near at hand, where they gather in a cluster, which quickly increases in size as it is joined by the rest of the swarm. The old queen, which has passed the winter with her colony, always leaves with the first swarm. Hives and all necessary appliances should be in readiness, that no time may be lost after the swarm has clustered, dispatch in hiving being all-important, as the longer it is delayed the more difficult the Bees are to handle. If the swarm is to occupy a frame-hive, this should, if possible, be furnished with clean empty comb. The advantage of this is that it enables the queen to commence laying without loss of time; otherwise sheets of comb—foundation or strips 1 inch or 2 inches wide, should be fixed on the underside of the top bars. As comb foundation contains sufficient wax in its projecting walls to enable the Bees to completely lengthen out the cells, it is only needful for them to provide wax for the cupplings. Thus a great amount of labour and much time are saved.

The swarm should first be hived in a straw skep, by holding it under the cluster while the brush on which it is hung is smartly shaken, causing the Bees to lose foothold and drop in a mass into the skep. They can then be shaken out on the tops of the frames, or upon the alighting-board of the hive. In either case, if the queen is with them, they will soon run in and form a cluster. Some persons have a great dread of being stung, which is a considerable drawback to their becoming proficient Bee-keepers, but the chances of being stung may be greatly reduced by wearing a veil when performing any operation in the apiary; and then Bees can be subdued by fumigation with the smoke of lighted brown paper, touchwood, fustian, etc., used in a bellows-smoker, by which the smoke can be puffed into any part of the hive desired. The idea of smoking Bees is not to stupefy them, but to alarm them, and cause them to fill themselves with honey, in which state they are but little disposed to use their stings, unless injured. Bees seldom sting when swarming, and the reason is that each individual, before leaving the hive, has gorged itself with honey. Gentleness, again, is a secret in the successful handling of Bees, for they are easily excited to anger by any quick or sudden movement of the hands. In examining a hive, a minute or two should be allowed after injecting a few puffs of smoke that the Bees may have time to freely partake of their stores; the hive may then be opened, and a little more smoke puffed in at the top of the hive as the coverings of the frames are gently removed. As the population of the hive increases, more room should be given (if swarms are not wanted) by tiering up or supering, adding one or more bodies containing either frames or section boxes—the frames for surplus honey for extracting, the sections for white comb honey. The uppermost frames or sections should be covered with some warm material in order to maintain a high temperature within the hive. S. S. G.

BIRDS.

Death of Canary (*Sergt.-Inst. J. Morris*).—In this case death appears to be due to inflammation of and internal hemorrhage of the lungs. The bird had evidently taken a sudden chill. Our changeable climate proves very trying to our feathered pets, especially at this season of the year, lung trouble being one of the most formidable complaints to which they are subject. The only chance of helping a bird over an attack of pneumonia is to keep it in a warm, moist atmosphere, and at an even temperature.—S. S. G.

Parrot with lame foot (*H. B. J.*).—If there is swelling in the claw and the bird has lost its appetite, but drinks more than usual, give it ten or twelve drops of Castor-oil, and put it on low diet for a time. The oil may be administered in a little bread and milk. The perch or floor may be padded that the bird may rest more comfortably. Possibly the claw has been injured through a blow or fall, or from becoming entangled in the bars of its cage. The injury may be situated in the leg or knee-joint. On examination, the foot, if misplaced, should be gently restored to its natural position, and supported by means of two thin splints of wood. Keep the bird in a quiet place where it will not be disturbed, that the injury may be the easier as quickly as possible. The best food for grey Parrots is Maize, hoiled till soft, then strained, and wiped dry. To this may be added in smaller quantities Canary-seed, Millet, Hemp, Oats, together with Nuts, Apples, or any fruit that may be in season. Animal food in any form, soap, and sweets should be carefully avoided.—S. S. G.

Photographs of Gardens, Plants, or Trees.—We offer each week a copy of the latest edition of the "English Flower Garden" for the best photograph of a garden or any of its contents, indoors or outdoors, sent to us in any one week. Second prize, Half a Guinea.

The Prize Winners this week are: 1, Mr. J. S. Taylor, The Gardens, Laundem House, Oundle, Northampton, for Lawn flower garden in front of house; 2, Mr. J. Ross, Oxford, for Primula nivalis. Digitized by Google

LAW AND CUSTOM.

Rights of garden tenant.—I have taken on a three years' agreement a small annexe to my present home, the annexe being really one large room, which I have rendered habitable. The garden to it was a sand-heap, and I am making and planting it. Will you tell me what things I may remove when I quit? Can I take away the edging of border-tiles I am putting down? The neighbours say I may take away anything that is loose or merely screwed, but nothing that is nailed. Is this correct?—Ara.

[Broadly speaking, your neighbours are correct. You may remove the border of edging tiles, but you can remove nothing that is firmly affixed to the freehold; hence, you can remove nothing that you plant if it takes root and grows. Things merely screwed to the freehold are not permanently but lightly affixed, and are generally removable.—K. C. T.]

Landlord and tenant—a tenant's claim.—B let a cottage and some ground to G on a yearly agreement to be determined by notice given at June quarter, no compensation to be payable by either side. B has now given G notice. In the ground let to G there is a board bearing the following notice: "This ground to be let for building purposes." There was no agreement about this notice board, but it has been there throughout G's tenancy. As he has paid rent for the ground, can he claim compensation for the occupation of the ground by the notice board?—B. C.

[Your statement implies that the notice board was there when G's tenancy began, and, if so, it was open to him to have made it a condition of the tenancy that the board should be removed; but he made no such condition, and he has allowed the board to remain without demur until notice to determine the tenancy has been given. Under the circumstances it must be presumed that the letting was subject to the right to place the board there, and no compensation can be enforced.—K. C. T.]

Garden let to tenant—winning coal-waste.—I took a house and a large garden at so much a year, payable half-yearly, but without any written agreement. I was under no restriction, but was at liberty to make what I could out of the garden. I kept fowls on a part of the ground, and one day a deep hole in this part and came upon coal. I bared the coal and got some of it up, and now my landlord has heard of it, and his solicitor demands to know what quantity I have got up, and intends to make me pay for it. As I took the garden to make what I could out of it, I contend I was justified in getting coal if there was any there. I may say that the coal would not repay the labour of getting.—C. O. G. E. R.

[You were clearly guilty of voluntary waste in digging the coal. You took the garden as a garden, and you did not take the minerals in the land, and it was an act of waste on your part to dig deep holes in the ground. I do not think, however, that the landlord will compel you to pay for the coal you have got, at any rate, not if you have sold none. It may be that it would not pay to hire men to get up the coal, but that is a matter of doubt, and if the coal lies as near the surface as you describe, I should think it will pay for getting. Let these things be as they may, I can assure you that you have been guilty of waste and are answerable to your landlord for the damage done, although the extent of the damage may not be great.—K. C. T.]

A nursery foreman's notice.—Six months ago I took a situation as foreman-manager in a newly-opened nursery at a certain wage, and a house was to be built in which I was to live, but, until it was built I was to have the use of another house. I removed from a considerable distance to this situation, and on my arrival I was told I must go into lodgings for a week or two, as my employer did not like to turn his good-paying tenant out. He has not yet turned him out, and I am still in lodgings. I was to have a share in the profits, and I have been working overtime to get the place started, for which I have received nothing extra. Now that I have got the place into going order, my employer has, without any reason whatever, given me a week's notice to determine my service, and says he can manage himself. I find he has tried to manage one of the men under me at a much less wage than he gives me, and I have to leave on a week's notice? As I have been in lodgings ever since I came, can I make any claim on this account?—C. K.

[The bargain was that a house was to be found you, and as a house was not found and you were directed to go into lodgings until such a time as a house was found, you may claim from your employer the cost of your lodgings, and if he will not pay, you may recover the same in the county court. It is not so clear what notice you are entitled to. From the number of questions asked as to the notice gardeners of various kinds may claim, it seems that no party to such a contract, neither employed nor employer, ever thinks of making a stipulation as to notice at the time of the engagement. Having regard to the fact that you were engaged as a foreman-manager, and

that a house was to be found you, and that you were to have a share in the profits, I think it is clear that neither party intended that the contract should be determined by a week's notice. In my opinion you are at least entitled to a month's notice. You do not say how you are paid, but in this case it does not really matter whether you are paid weekly or not.—K. C. T.]

CORRESPONDENCE.

Questions.—Queries and answers are inserted in *GARDENING ILLUSTRATED* if correspondents follow these rules: All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF *GARDENING ILLUSTRATED*, 11, Farnwood-street, Holborn, London, E.C. Letters on business should be sent to the PUBLISHERS. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper, and not more than three queries should be sent at a time. Correspondents should bear in mind that, as *GARDENING ILLUSTRATED* has to be sent to press some time in advance of date, queries cannot always be replied to in the issue immediately following the receipt of their communication. We do not reply to queries by post.

Naming fruit.—Readers who desire our help in naming fruit should bear in mind that several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. The difference between varieties of fruits are, in many cases, so trifling that it is necessary that three specimens of each kind should be sent. We can undertake to name only four varieties at a time, and these only when the above directions are observed.

PLANTS AND FLOWERS.

Anomatheca cruenta (*G. M. S.*).—This is a pretty little South African bulb belonging to the Iris family. It grows from 6 inches to 12 inches high, with carmine-crimson flowers, three of the lower segments marked with a dark spot. It is hardy on warm soils, but in others it should be planted on slopes, in very dry, sandy soil, or on warm borders, the bulbs being planted rather deep. In many soils it increases rapidly.

Rose Marechal Niel buds not opening (*Robert Newton*).—This Rose often produces more buds than come to perfect flowers. In what condition are the main stems? Are there any signs of canker? The non-swelling of the buds arises, no doubt, from there being too many for the plant, or lack of vital power in the plant in some forms. You might try what a little artificial stimulant in the way of manure-water will do.

Plant for background (*Swiss Sittlerher*).—There is some difficulty in this, as you doubtless require a plant as free and profuse in flowering as the Ivy-leaved Pelargonium, and we regret it is not forthcoming. *Salvia patens* would look well, but we fear it would not stand the heat, and the beautiful scarlet *Salvia* would not do at all in the circumstances. It is possible you may find a better plant in some of the warmth-loving annuals, such as the *Celosia*, *Love-lies-bleeding*, or similar plant. *Nelium-tus eucamerifolius* would do quite well, from the heat enduring side of the question, but it may be too tall for your purpose. It grows 3 feet high. Another plant is the annual *Gallardia*, which is showy and free. The old scarlet *Pelargonium* is often derided, but a better plant, with great freedom of blooming in dry and hot places, has not yet been found, and is such as the *Tuberous Begonia* is quite useful.

Outdoor Auriculas (*B. Ledward*).—Few hardy plants need less attention than do outdoor or border Auriculas. If you do not wish to save seed from your plants, pinch out the flower-stems low down so soon as the bloom is over, and if you have any old pot soil, or indeed any fairly good soil, run through a sieve, and place some of it about the plants, as it will assist new roots, which then generally break out from the base of the leafage. That so far relates to leaving the plants alone, and so treated they often grow into large clumps. If you wish to propagate the plants, you may, the moment the bloom is over, lift them, divide, cutting away any long or apparently decaying root-stock, and replant in good soil under the shade of a north wall, giving water in hot, dry weather. If, if preferred, you may leave the replanting until next October. Still, then the plants are slow in forming new roots.

Anemones (*Anemone fulgens*).—In the majority of instances lifting and a short, complete rest are beneficial, particularly for the "mixed" kinds, which we presume are the form of *A. coronaria*. Do not, however, lift them till well after the leafage has disappeared, then place the tubers in sand or rather dry soil, so that the enforced rest may be gradual as well as complete. Later on remove the tubers to quite dry sand, and keep them so till October or November, when you may replant them. With *A. fulgens* the case is indifferent, and in scarcely any two instances will the same experience give identical results. We know an instance where the plant is employed as a spring bedder where formerly the custom was to dry it off each year. So many failed to flower by this treatment that now the tubers are lifted soon after flowering is over, and heeled in in old potting soil under a north wall, and there they remain and re-start into growth, when they are lifted en bloc with spade and replanted in the beds, giving the first at results possible.

Remaking Lily of the Valley bed (*J. W. F.*).—Early autumn is the best season for such work. As the bed is an old one, the Lily roots have doubtless become crowded, and an impoverished condition generally has resulted. Select a fresh position, where fresh soil would be at hand. If this cannot be done, give an entire change of soil, taking out fully 15 inches of the old, and replacing by a like quantity from another part of the garden. Dig in plenty of very old manure and leaf-soil, if possible. Some care will be required in digging out the old bed.

FRUIT.

MILDEWED VINES.

Having taken your very useful and practical paper for some time, I am sending by post a small bunch of grapes with two leaves. I am afraid they show mildew, and I should feel grateful if you would tell me, if that is the case, what I can do to get rid of it? I have nine vines in my house, and they have been more or less affected the last three years. The house is full of plants at present, but I hope to get them out next week. In the winter I dug out the roots of the vines, removed the old soil, and put in loam and a sprinkling of 4-inch bones, and the growth is very vigorous, as shown by the large size of the leaf on—S. P.

[Undoubtedly your vines are affected with mildew, and in a very severe form. It would have been better had you sought advice earlier, especially as you say they have been affected more or less for the last three years. Neither the leaves nor the bunch you send display any sign of vigour, rather, we should say, they were in a very debilitated state. You give us no information in helping to form an opinion as to the cause, but we may say that mildew comes from inattention to watering of the borders, from negligent ventilation, or from low, damp situations, with the border not well drained. Flowers of sulphur is the common remedy for mildew as affecting the leaves and bunches, applied in a dry state. It is impossible for you to clear the disease out in one season, because mildew is such a persistent fungoid growth once it gets a footing. We presume, although you do not say so, that your vinery is heated with hot-water pipes. If this is so, coat these with sulphur, first reduced with water or skim milk to a paint-like consistency, and maintain some heat in them regularly, and at night in particular, to a sufficient degree to give off a sulphurous vapour. With vines so badly infested persistent effort will have to be maintained ere this can be effectually checked. Procure some sulphate of iron in a powdered form from a horticultural sundriesman, and apply this to the border at the rate of an ounce to each square yard of surface, and water it in. Repeat the application in about two months' time, and you will find this a great help in getting at the root of the evil. In the meantime see that the border is in a proper state of moisture, not saturated on the one hand, or dry on the other, for these extremes are conducive to the mildew. It would be well, too, in order to assist as much as possible in keeping the foliage coated with a film of sulphur, to reduce lateral growth weekly to the point of origin. What is known as sublimed sulphur is the better article to procure for your purpose, though it is not strictly material. You should apply the fresh sulphur at least once a week in light dustings to the leaves and bunches, and, if this is well followed up, there will be less trouble in future. Ventilation should be given early in the morning, particularly if the aspect is one that invites the early sun. It is well known that to allow the sun to shine on the roof for any length of time in the morning before air is admitted conduces to the attack of mildew, even in otherwise healthy and vigorous vines. The same effects do not arise from closing the house in the afternoon when the sun is

declining; indeed, it is invigorating to the vines to close the ventilators sufficiently early to husband warmth from the declining sun. The growing of a quantity of plants in the vinery is not considered a good practice, and, in the case of mildewed vines, it certainly is not favourable. There are, however, thousands of vineries in which plant growing is of necessity practised, and it is possible, under good management, for both to grow together in harmony. In the winter it will be necessary to thoroughly clean the roof, stages, and walls, and to paint the vines with a sulphur concoction, so as to destroy the germs that may lurk in the bark and spurs, and later in spring, when the vines advance into leaf growth, employ the dry sulphur, then you may, with other suitable attention, subdue the evil.]

RASPBERRIES.

Raspberries will thrive and bear fruit in almost any kind of soil that is well manured; but the finest fruit is produced by plants growing in a deep, rich loam. Raspberries produce a thick mass of fibres near the surface, and therefore are very susceptible to drought, which causes the fruit to come small and shrivelled. Before a new plantation is made, the ground should be trenched two good spits deep, or, what is better, 2½ feet. This must, however, in some measure depend on the character of the sub-soil, as if it be of an inferior quality it will not be advisable to bring much of it to the surface. When trenching, plenty of manure or garden refuse should be worked into the ground. The best time for planting is as soon as the canes have shed their leaves. The mode of planting must, in some measure, be regulated by the form in which the canes are intended to be trained. Where stakes are available, the simplest plan is to tie the bearing canes to them, taking care that they are securely fixed in the soil. The stakes should stand out of the soil about 4½ feet, and to each of them should be tied, when the plants have become established, five or six of the strongest and best placed canes from each stool after the fruiting canes of the previous season have been removed. They should be planted in lines not less than 5 feet apart, and the distance asunder in the line should be the same, or not less than 4 feet. They will not throw up very strong growths the first year, but if the fruit be sacrificed and the canes cut to within 1 foot of the ground, they will throw up much stronger canes the following season. Another mode of training consists in placing strong posts at each end of the row, connecting these with galvanised wires, strained through intervening iron standards. Thus a trellis is formed on which the canes are trained, and, if properly fixed, a plantation of raspberries thus treated will last for years. Where this system is adopted the canes should be planted about 1 foot apart, and the shoots should be trained a little diagonally. Some growers dispense wholly with supports; merely placing the canes in bundles and uniting the tops from each end of the row. Thus forming a series of arches on which the fruit is borne.

After planting, surface-dress with decayed manure. During the summer the ground must be kept clear of weeds and the soil occasionally loosened with the Dutch hoe. When the plants have become established and made about a foot of new wood, all useless suckers should be pulled away in order to admit light and air to such canes as are selected to remain. When the fruit is gathered the canes that have borne it should be at once cut out, so as to give increased space to those intended to bear next year's crop, and as soon as the leaves have fallen the latter should be thinned and regulated. After regulating the canes, some recommend that the ground be dug and a quantity of manure worked in about the roots, but it is questionable whether such practice is not a mistake. A better plan is to loosen the surface with a steel fork, and then to mulch with 2 inches or 3 inches of decayed manure, which will protect the surface roots from frost in winter and drought in summer.

T.

NOTES AND REPLIES.

Melon fruits not swelling (J. W. W.).—There must be some local reason accounting for your failure, for, as a rule, if melons set there is no further trouble as regards their swelling. They must, however, be set all together, or they fail in the manner you complain of. In pots there is much greater uncertainty, and especially in those of so small a size. Ten-inch pots are not large enough, and the evil of this restriction is further accentuated by their close proximity to hot water pipes. Feeding with manure of any sort we have proved to be fatal to setting and swelling of melons in pots, and this may be the cause of your complaint. Clear water only should be given until they have set. If you have not already done so, you should give lime to the soil, preferably that which is air-slaked, and in planting or top-dressing add this to the soil. Some soils are very deficient in lime, and if this is so naturally, then the necessity of applying it by hand is apparent. Herein may be found a further cause of your failure. Melon growing may be easy, or it may prove just the contrary, as so much depends on the daily attention, the season, soil, and local conditions. We have found that it is not sufficient in melon growing to just fill the pots or make up a bed and consider this sufficient to carry them through to maturity. A little addition of new soil occasionally has a marked influence on their growth. One may feed with the best of manures, liquid or dry, but with soil crammed with hungry roots this does not satisfy every demand. If new roots can be encouraged there is material for supporting both the swelling fruit and leaf growth. If your fruits fail to swell, the only alternative is to wait for more flowers to open and set, and to proceed on the lines above stated, and endeavour to encourage and maintain new root formation by additions of new soil on the surface, both in pots and borders, not omitting lime in small doses occasionally. Do not, however, give lime and dry manures together, but rather as

an alternative course. A rim may be constructed on the edge of the pot with wet clay or turf to facilitate the soil additions.

Newly planted Vines unpruned.—Early in March I planted four Grape-Vines in a prepared outside border, the canes being brought into theinery, which is a cool one. My gardener is allowing all the laterals inside to grow, but proposes to stop them when a certain length. Some of my friends tell me this is all wrong, and I find in your issue of April 10th an answer to a query in which you say, "Newly planted Vines are by all good gardeners cut down to within a short distance of the soil." I wish I had noticed this before. Now, the question is, ought I to do this now? Some of the laterals are from 7 inches to 9 inches long. I am anxious to make theinery a success, and would be much obliged if you would tell me how to rectify the error I have committed!—S. H. A.

[The practice of cutting back newly-planted Vines is one universally adopted. Where this is not done there is not usually the same satisfaction derived from their progress. It would be well, even though your Vines have so far expended themselves, to reduce the laterals back from the point downwards, so as to strengthen the one chosen for the future permanent rod. It often happens that when newly planted Vines have reached the limit of the first growth, which in reality is stored in the embryo bud and unaffected by spring roots, they remain stationary, or almost so, and their future is both slow and unsatisfactory from a growing as well as a fruiting point of view. From these remarks you will observe that the chances of rectifying the error are not by any means certain. On the other hand, it would, we think, be better to sacrifice the existing lateral growth to a point where a strong shoot would conveniently form a permanent cane. By this time your Vines have reached a stage when roots should be active. You will probably find the strongest shoots on your Vines near the extremities of the canes, and those nearer the soil weaker. By a course of pruning the cane while in a dormant state this is changed somewhat, a strong shoot coming from the point to which it has been pruned. Pinching of the shoots when they have reached a certain length is not in itself sufficient. The ascending sap travels to the extremity, giving greater strength to the laterals at that point, and this same influence will be felt in the future. A young nursery-grown Vine is grown in a hurry, and prepared only for sale. When it passes into the hands of a permanent owner its course has to be modified and so dealt with as to build up a solid foundation. The unpruned cane would never swell up in its lower portion at the same rate as the uppermost; consequently, the Vine would become largest at the top instead of at the base near the soil. Permanent Vines need to be dealt with so as to encourage a production of stem from the border to the extreme end, and this comes from pruning and pinching.]

Diseased Apple-trees.—I enclose branches of some young Apple-trees, and would be much obliged if you would kindly say what is killing them, and what remedy (if any) I could apply? Some of the trees were planted by me two years since, when I got the orchard, others some four or five years previously. There were old trees in all the places some years since, but the young ones have not been planted exactly where the old ones stood, as the old ones were large standards and the young ones are pyramids and bushes, planted more closely than the old ones, and the places where the old ones stood were tilled (vegetables) for some years before being replanted. The youngest trees are bushes on Paradise-stocks, and the ones planted four or five years pyramids on, I believe, Crab-stocks. The largest branch I send has the leaves quite healthy on it until two or three days since. Would American blight be the cause? I had a good deal of this last autumn, but did not notice this effect at that time; in fact, I had very little of this disease, whatever it may be, until just lately.—J. C. Bantry.

[We see no present evidences of American blight on the portion of Apple-trees sent. In one case there is ample evidence of the existence of a fungoid or mildew attack, and what is known as the Apple Oidium. That refers to the portions mentioned as having been healthy up to a few days previous to sending. The other shows in the wood evidence of canker, as the bark is shrivelled and the leafage bears evidence of injury by sharp, late frosts. It seems as if the wood had suffered from the same cause, but in both cases mildew is there. Is it right to assume that the position of your orchard is low and damp, and that the summer wood does not ripen well? In any case, we think it would be wise to lift and replant the trees in the winter, adding to the soil a quantity of wood-ashes and sifted old mortar-refuse. A few weeks later prune rather hard to induce the formation of new healthy wood. But you may at once make a sulphate of copper

solution. Get 2 lb. of that material (bluestone), and dissolve in a large wooden tub in boiling water. Dissolve in a pail 2 lb. of lime (fresh), then pour the liquid into the tub, add 2 lb. of soft-soap, and then 30 gallons of water. With that gently spray or syringe your Apple-trees at once, doing so in the evening, and give a second spraying three weeks later. That should kill the mildew. A fine winter wash or spray is 1 lb. of caustic soda, 1 lb. of commercial potash, dissolved in water, then add 15 gallons of water, and use it as hot as can be borne. That dressing is a great cleanser. It should be applied only when the trees are at rest, but not in frosty weather. After all, soils and climatic conditions have more to do with these fungoid attacks than has anything else.]

TREES AND SHRUBS.

MAGNOLIA STELLATA.

This is the smallest of the hardy Magnolias, being a shrub rather than a tree, though, in

Magnolia stellata growing against a wall in Col. Baskerville's garden at Crowley Park, Henley-on-Thames. From a photograph by Mr. T. Taylor.

places where it has been planted for a long time and thriven well, it is as much as 12 feet high. Specimens 4 feet and 5 feet high may well rank among the loveliest of spring flowering shrubs. Its fragrant blossoms are pure white, and the numerous strap-shaped, radiating petals distinguish this from all other Magnolias. As this, like all the Magnolias, resents being moved, it should be placed in its permanent position as soon as possible. An addition of peat to the staple soil helps this Magnolia considerably. It is not absolutely necessary, as it will thrive in any good open loam; but peat is worth adding to the soil, especially as a means of bringing on young plants. It is a native of Japan, and, besides the older and correct name here given, is known also as *M. Halleana*.

Growing Broom.—I should be glad to know how to cultivate the common Broom. It seems difficult to transplant. Would it be better to grow it from seed? When should the seed be sown? Is Broom a fairly quick grower?—SHERWOOD.

[Yes, it is far the better way to raise from seed. Sow at once. Broom grows very fast if protected from rabbits.]

PLANTS AND FLOWERS.

CHRYSANTHEMUMS.

SEASONABLE NOTES.

THE cold and unseasonable weather of late has been all against the plants making satisfactory progress, and at the time of writing, generally speaking, their appearance is anything but what it ought to be. A curious feature of the unfavourable season has been the slow growth of those sorts which were pinched in the early spring. As a rule, plants treated in this way usually develop freely new lateral shoots, but this season the new growths were much longer than usual in developing. Unless a position could be found in which protection could be afforded against the cold easterly and northerly winds, it has been much better to keep the plants in cold frames, leaving the lights tilted. In exposed situations I have seen plants which have been injured by the exceptionally severe frosts (9 degs. May 15th),

and many of the plants, too, have been partially denuded of their foliage. The grower must always act according to the climatic conditions prevailing at the time. A close observation of the plants, especially those which were pinched or stopped, will in all probability disclose many of the young lateral shoots infested with green-fly, and if this be so, means should be taken at once to rid the plants of this pest. It is astonishing how quickly a dusting with Tobacco-powder will render their surroundings untenable, and if any happen to be left, do not fail to repeat the dose. Black fly is troublesome in some collections, and is often found more difficult to eradicate than the green form. Much depends upon taking the black fly in hand in good time—in fact, immediately it is first seen. I have seen plants which have been neglected in this respect for a little while, and in the interval their numbers have been nothing short of marvellous. The difficulty then in removing the pest is considerably increased, and the plants naturally must suffer in consequence. Another seemingly insignificant matter is the removal of weeds from the surface

soil in the pots. However careful a grower may be, weeds will develop; but this need not cause much concern, provided they are removed while they are very small. The rich character of the soil and the daily attention which the plants receive in the way of watering, etc., naturally promote growth of a robust and vigorous kind, and weeds luxuriate and attain such proportions that their removal causes some trouble. In the process of uprooting the weeds the surface roots are interfered with, and not infrequently laid bare, and under such treatment the plants must suffer in consequence.

Now that the plants are becoming well rooted in their 5-inch or 6-inch pots, more attention will have to be paid to watering. It is only reasonable to assume that we are now approaching warmer weather, and well-rooted and vigorous-growing plants will need copious supplies of water two or three times each day. A single day's neglect of this timely application of clear water may irreparably blight the prospect of would-be exhibitors. If stakes for their support are not yet inserted, the sooner this is done the better. There are no better stakes than Hazel rods, and if the grower cannot cut these out of his own hedge, he can buy a large bundle very cheaply indeed. That damage may not be done to the roots, see that the end of the stake which has to be inserted is nicely sharpened, and introduce this into the soil at a spot some distance removed from the stem of the plant. Use raffia for tying, leaving sufficient space in each loop for the stem to expand. The final potting should not be done till the pots are well filled with roots. E. G.

By now the bulk of the plants will be in their flowering pots, and preparations should be made to put them in their summer quarters, so that the wood may be ripened properly. The wider apart the plants stand from one another in the rows the dwarter they will be, and the wood will be much better ripened in consequence. When staking the plants each should be carefully looked over, and all traces of green fly removed; they hide in the young growing point of the shoot and cripple it considerably. I have often seen plants look quite free from fly on the outer leaves, and find them in numbers in the inside of the developing leaf. Where plenty of coal-ashes is procurable the pots may be plunged three parts up in same. This has two distinct advantages, as it keeps the plants from being blown over and saves the labour of watering too frequently. When the pots are exposed to the sun's rays for any length of time and get dry, the roots get scorched and the plants receive a serious check thereby. When they cannot be plunged they should be stood on a firm bed of ashes, and, in the event of a hot sun, boards or slates should be laid on their edges, so as to protect the pots. In this case it will also be necessary to secure the plants from wind, and nothing is better than a wire stretched between two strong stakes fixed in the ground at each end of a row; the stakes can then be easily secured to the wire. A good syringing of rain water after a hot day is very beneficial, this promoting healthy foliage and clean plants. Bridge-of-Weir, N.B. D. G. McL.

SPECIMEN PLANTS.

A FEW of these in the conservatory look exceedingly well at the dull season. Anyone having a few old stools from last season on hand may use them for the purpose, and, although the flowers may be small, still, the quantity will make up for the deficiency. To make good plants the stools should be potted into 5-inch pots in any good soil. The old ball may have to be reduced to fit these, but it will do them no harm. After potting, give them a little

warmth, when they will soon start away, especially if they receive a light syringing frequently. The shoots will come in excess of the number required, and should be thinned to nine or a dozen, taking care to cut out the weakest growths only.

When they have attained to the height of 6 inches or so pinch out the points of each shoot in the usual manner, the growths resulting from this pinching being treated in a similar fashion when 6 inches more of growth have been made. This should be continued until you have from thirty to forty shoots, which should make a grand specimen. All growths must be carefully tied out as they grow, to allow all the light and air possible to the centre of the plant. To encourage an even growth on both sides the plants should stand in rows running due north and south. They may be shifted from the 5-inch pots to 9-inch or 10-inch pots, in which they will flower well. When the buds appear, thin to one on each shoot in the case of Japanese varieties. The Pompon, reflexed, etc., may be allowed to open all their blooms. A little soot-water occasionally is very beneficial, and a stimulant should be given weekly after the buds appear. The good old white Pompon, Saer Melanie, treated

before, as we could easily have assisted you to treat your plants in order that they might develop nine blooms on each plant. You say you want your plants to bloom by the end of October, but we fear this is impossible if you want as many as nine blooms to finish satisfactorily. There is even now a difficulty in assuring a limited display at the time named, and we can only give you a general rule to follow, hoping thereby that the varieties you have are not late mid-season kinds. Your plants, from the description given, are now in 10-inch pots—a very large size in which to find plants so early in the summer. We assume that each plant has been potted up from time to time into pots of varying size, beginning first with 3-inch, then 5-inch or 6-inch pots, and finally into those measuring 10 inches across. If this be so, then they should be in a very forward state, and we should pinch out the point of each plant and grow on as many of the resulting shoots as develop satisfactorily. The chances are that not more than four or five shoots will develop, and these will quickly be seen forming in the axils of the leaves. Provided you keep the plants rather dry at the roots for a few days, you should hurry forward the subsequent growths, and when they are

Magnolia stellata in the open in Messrs. Barr's nursery at Tlaines Ditton. From a photograph by G. A. Champion. (See page 188.)

as a specimen, gives grand results, plants sometimes measuring 5 feet high and 3 feet through. D. McL.

Bridge-of-Weir, N.B.

NOTES AND REPLIES.

Good early-flowering Chrysanthemums.—Too many of these have indifferent growth. The model variety is undoubtedly Mme. Marie Masse. It is early, free-blooming, forms abundant growth, and is hardy enough to stand the winter in the open. Fortunately, this kind has produced several "sports," differing only in the colour of the flowers. The type is pink. A creamy-white is Ralph Curtis. From this we may eventually obtain a pure white. Rabbie Burns has blooms of a salmon-pink tint and very pretty. "Crimson" Mme. Marie Masse is in reality a bronze, ranging in shades of colour. From this has come Horace Martin, a rich yellow flower, and not the least valuable of all the sports.—H. S.

Chrysanthemums for exhibition.—I would be glad to know how Chrysanthemums ought to be grown so as to have one clear stem, with not less than nine good show blooms on them, by the end of October? My Chrysanthemums are now nice plants, with one stem about 2 ft. high, and have not yet been stopped. They are in pots 10 inches high and 10 inches across.—B. E. [It is a pity that your query was not sent us

sufficiently developed they should be grown on as quickly as possible. There is just one chance whereby you may get the desired number of shoots, but that depends upon the weather during June. If by the last week in June the new shoots above referred to have attained a length of a few inches, they may in turn be pinched out, and the new shoots subsequently developing grown on. In this way then you may, even at this late date, be successful, but another season commence these operations in late March or early April, and grow on the resulting shoots to the second crown-buds.—E. G.]

Early Chrysanthemum White Quintus.—This was obtained from the mauve-pink O. J. Quintus, and is a valuable plant. Could it be induced to bloom in September instead of October it would be by far the best white early sort, better than the well-known Mme. Desgrange. The blooms are of fine quality, and the plant is bushy and free. If it be planted in a position—such as at the foot of a wall—where protection may be given, one can keep the flowers clean, and they open well. This, too, is capital as a pot plant and will pay market men. White Quintus and O. J. Quintus should be the first two kinds to be thought of to supply blooms early in October.—H. S.

ROSES.

ROSES IN CUMBERLAND.

My garden is situated in east Cumberland, 800 feet above the sea, and lies on a slope to the north-east. The climate is considered a severe one, especially in the late spring, when sharp frosts, amounting to several degrees, and accompanied by snow showers, often visit us as late as the middle of May; the surrounding hills are constantly snow-tipped till June, and vegetation is, therefore, very slow and backward, while the late frosts often cause great havoc among the early-flowering plants and fruit-trees. Although the aspect does not sound a good one for a garden, I have succeeded, in so far that Roses, herbaceous and other plants, as well as vegetables, have done well; but probably this success is chiefly due to the fact that the soil is particularly good. It is a rich, deep, red-coloured loam in most parts, but here and there it has a good deal of clay in it. The rock of the country is carboniferous limestone, with thin beds of shale and sandstone, and it is on one of the latter that this house and garden stand. I have two Rose borders, with a Grass path between them; each border is 6 feet 6 inches in breadth and 58 yards in length, and has a wire espalier at the back of it. I first planted the Roses there in October, 1879. I have a number of varieties, both of Teas, Hybrid Teas, Hybrid Perpetuals, Noisettes, Bourbons, Chinas, and Polyantha Roses. The first winter I protected the plants with Bracken, but in spite of that precaution a good many died. The last winters I have given them no protection except the ordinary mulching, and I am glad to say every year my losses have been fewer, and this spring I have only found one dead. The first summer the Roses did only fairly well, and were very late in coming into bloom, and that autumn I replanted nearly all, putting them deeper into the ground, so that the soil covered the grafts. Each succeeding year since then they have, I think, flowered better than the last, and they are generally in their fullest bloom about the first week in July. I treat them in the ordinary way, giving them a good mulch of well decayed manure in November or December, and sometimes I have put on basic slag at the same time. Towards the end of March or beginning of April I dig in the manure lightly, and after that I prune. But the great secret of success is, in my opinion, letting the air into the soil by keeping the hoe constantly at work in the summer, so much advocated in GARDENING. The Hybrid Teas have succeeded best of all with me, especially that most lovely one Mme. Jules Grolez. I always wonder this Rose is not more often mentioned in articles and books on gardening, as it possesses nearly every good quality that can be desired. The colour is exquisite, it has a lovely bud, and a beautiful bloom when full blown; it is very hardy, a continuous bloomer, flowering both early and late, its only fault being that the flowers last so short a time when cut. Guillot sent it to me in 1897, the year he brought it out, and every succeeding year I have added to my stock. The other Hybrid Teas which have done well are Cameos, Kaiserin Augusta Victoria, Lady Mary Fitzwilliam, Marquise de Salisbury, Viscountess Folkestone, Triomphe de Pernet Père, Archiduchesse Marie Immaculata, Grace Darling, Progress, Mme. Caroline Testout, Gruss an Teplitz, and Papa Gontier. The Tea Rose that has answered best is Princesse de Sagan, and I must mention, in speaking of this Rose, that it does well under certain trees, such as Apple or Thorn-trees, but unfortunately its propensity to creep along the ground makes it troublesome to manage, otherwise it has the merit of being a good dark red colour, which does not change after it comes out into full bloom. Other Teas are Socrates, Souvenir de S. A. Prince, Mme. Berard, Mme. Bmy, Rubens, Mme. Creux, Ma Capucine, Iyon, Edith Gifford, Mme. Chedane Guinoisseau, Christine de Noué, and that lovely Rose, Souvenir de Catherine Guillot. Of Noisettes I have Ophir, W. A. Richardson, Alistair Stella Gray, Mme. Pierre Cochet, and a not very well-known Rose, Wassil. Chloé. The last is not a profuse bloomer, but has now

of a lovely colour and shape, which last well when cut. All the Chinas that I have here have done well—namely, Mme. Laurette Messimy, Mme. Eugène Resal, Cramoisi-Superieure, Fellenberg, and the very pretty apricot-coloured Queen Mab. Of Hybrid Perpetuals, those which have done best are Duke of Edinburgh, General Jacqueminot, Pride of Waltham, Her Majesty, Merveille de Lyon, Prince C. de Rohan, Mme. Gabriel Luizet, Mrs. John Laing, and Empereur de Maroc. Of this last I had some good-sized blooms on a plant on its own roots. The Crimson Rambler does very well against the espalier at the back of the Rose border, and as an edging I have Gloire des Polyanthas, which seems to bloom almost incessantly. I have absolutely failed with certain Roses; these are Etoile de Lyon, Jean Ducher, and Homère. Their foliage generally looks exceedingly healthy, and they have been covered with buds, but these drop off before they open. I am trying a yellow Banksian Rose against a S.E. wall, and it has stood the last two winters, which have been more than ordinarily severe. It has now, May 22nd, a number of buds upon it, but whether they will really open or not is doubtful, as we are having such intense cold.

I have been very successful with cuttings, owing to a method for the knowledge of which I am indebted to a friend and neighbour. Her plan is to trench the ground very deeply under a wall with a sunny aspect, either south, south-east, or south-west, then in October to cut off the long autumn shoots and put them in as deeply as possible, treading the soil down firmly round them. Of those Roses which do not make long shoots I put in short cuttings made in the ordinary way, and many of these have grown also; but the long ones generally do better and make large plants at once. The year that I first tried this method I only put in two cuttings—one of Jules Margottin, the other of Bouquet d'Or. The following summer the Jules Margottin had a number of blooms on it, and every year since then it has flowered profusely. The Bouquet d'Or also grew, but did not flower till the third year. Cuttings from the following Roses have also done well and flowered the first year: Crimson Rambler, Ophir, Alistair Stella Gray, Mme. Pierre Cochet, and Mme. Jules Grolez.

Penrith.

M. L. P.

NOTES AND REPLIES.

Rose growths diseased.—Shall be greatly obliged if you will inform me through your paper if the enclosed Roses are diseased, also name and remedy?—
LEASRICH PARK.

[We do not detect any sign of disease in the growths submitted to us. In our opinion, poverty of soil is responsible for much of the debilitated growth, and also the plants should have been more severely pruned. It is useless to retain thin, unripened growths on Tea Roses. They are sure to fail just when wanted to develop a blossom. The largest growths of Mme. Lambert should have been cut back to the plump, dormant buds, and the thin, soft shoots would have been better cut clean away. If a Tea Rose is healthy at the root one need not fear cutting it back too hard, although where the growth is thoroughly hard it is advisable to retain such well-ripened shoots a good length. The growth of the Hybrid Perpetual or Hybrid Tea sent should have been pruned more severely. We should advise a dressing at once of some good artificial manure, keeping this well hood in.]

Treatment of Tea Roses.—Please tell me what is the best treatment for Tea Roses? I have some which seem to be suffering from want of nourishment, although there are some growth and some bloom. Could I pot now? There is some mildew amongst them.—JACK.

[We presume your plants are now growing in pots, as you say there is some bloom. It is a pity you do not furnish us with more particulars, such as the age of the plants, the size of the pots they are now in, and when last repotted. Generally speaking, pot Roses are repotted too frequently, but when there seems a lack of vigour, repotting is the best remedy. It is a very safe plan to repot when it is known the present pots are full of roots, and the best time to do the work would be as soon as the plants have blossomed. We much prefer to repot Roses in June or July, they then have two or three months of genial weather in which to lay hold of the new soil before winter sets in. You

can give your plants now much assistance in the shape of liquid-manure. Water the plants first with plain water, then give them some of the liquid-manure. Place an old tub or cask in some out-of-the-way corner, put about a bushel of oow-manure in a bag, and a peck of soot in another bag, then fill tub with water. Allow this to stand for a day or two, then use it about half strength and once a week. It is very important that the liquid be clear. Anything that tends to prevent a free circulation of air in the soil is to be avoided.]

Rose Crimson Rambler foliage turning yellow (L. S.).—The recent cold nights have been undoubtedly a cause of the foliage turning yellow and falling off. The growths may also be partially injured. We have noticed many of the brown blotches in the hard wood of climbing Roses this year. Many believe this to be caused by the frost, others to insect punctures; in any case, the vigour of the new shoots is never so pronounced upon growths affected in this manner. There is yet another detail that may be responsible for this yellow foliage, and also the brown spots on the other leaf sent, and that is defective drainage, coupled with want of thinning of the growths. You must remember that a leaf has most important functions to perform, and unless it can receive abundance of air and light, the leaf will suffer, and parasitic pests soon take possession. In like manner, stagnation of water so that roots cannot act freely are most fruitful causes of these disorders. We should advise you to spread out the growths of the Crimson Rambler as much as practicable, and thin shoots of other kinds at same time. Keep the soil well aerated by frequent hoeings. In the case of "black spot," this is usually caused by an over-abundance of moisture at night, or the growths are too crowded to permit of the foliage receiving sufficient air. A good syringing with a fungicide will prevent its further progress. A very safe remedy is liver of sulphur. If the weather is cool and damp, you can use it at the rate of 1 oz. to 3 gallons of water; but if the weather is hot and bright, 1 oz. in 6 gallons or 7 gillons of water is the right proportion. Add enough soft-soap in either case to make a good lather. It is best applied in the evening. Only procure a small quantity at a time, as it is best to use it fresh. Unless your Roses are badly affected with black spot we think you need not be alarmed, as it will probably disappear as soon as good growing weather sets in.

Dark Rose for cool greenhouse.—Will you kindly tell me the name of the best dark red Rose to plant in a border against the south wall of a cool greenhouse? I have now a Marshal Niel and W. A. Richardson in the border, but they both have canker. The house has an earth floor, and is rather damp in winter. I should be glad to know if that would cause the canker? Also, would you tell me of any other climbers more suitable than Roses for the border? Would a Bougainvillea do?—JAY.

[We think you would be pleased with Monsieur Desir. It is a lovely Rose, velvety crimson in colour, with violet shading. Some of the dark Hybrid Perpetuals would also succeed on such a wall, especially if planted out in a well-prepared border. Charles Lefehvre, Ella Gordon, Jubilee, and Mme. Victor Verdier would all be good; Jubilee is the darkest. If you elect to plant one of these, procure a plant established in an 8-inch pot, and prune very sparingly. If planted out at once it would make a good growth during summer, and its growth would become well ripened, so that it would blossom well next year. As the floor of house is rather damp, you would do well to provide some artificial drainage for the border. Let the soil be thrown out to a depth of 2 feet 6 inches, put 6 inches of rubble, such as stones or broken bricks, in bottom, then return soil, or, better still, add some good loam from a pasture instead of all the old soil. Some well-rotted farmyard-manure should also be incorporated with the soil at the rate of about one part of the former to three of the latter. A Bougainvillea would not do well in such a house, but you could grow any of the following climbers: Scarlet Trumpet Honeysuckle, Clematis, Ceanothus (Gloire des Versailles, Habrothamnus elegans, Abutilon of sorts, Bignonia grandiflora, Platanus revolutum, Passion-flowers, Plumbago capensis, Fuchsias, Ipheiotropæ, or Tecoma jasminoides.]

INDOOR PLANTS.

BEGONIAS IN HANGING BASKETS.

fused with rose. This Begonia has been grown in England for nearly twenty years, but not always under the above name; indeed, it is also met with as *Begonia Limmingei*, *B. undulata*, and *B. glaucophylla*, this last being by botanists regarded as the correct name. It is a native of Brazil. By far the finest example that has come under my observation is in the Mexican house at Kew. It is now about a year since I was particularly struck with its imposing appearance, forming as it did a mass of foliage and flowers over 6 feet in depth and

summer months. *B. foliosa* or *microphylla* is also a very pretty basket plant, but much less vigorous than the preceding. The slender branching stems, clothed with small deep green leaves, present a frond-like appearance, while the small white flowers borne in early summer impart quite an additional feature to the plant. It is a native of New Granada.

In addition to these, some of the tuberous-rooted varieties do well in baskets. The very features which form an ideal pot-plant—that is to say, compact growth and large, upright blossoms—are against the basket varieties, for in their case the most desirable points are a loose style of growth and medium-sized flowers, freely produced. Though there are many named kinds, the majority of the tuberous-rooted varieties are raised from seeds, and when this is done, owing to variation incidental to seedlings, it will be easy to select those most suitable for baskets, as well as for pot culture or bedding. Tubers from one to three years old are the best for baskets. The better way is to start them in comparatively small pots, and plant them in the basket when they have started into growth. Though requiring a warmer structure than an ordinary greenhouse, that popular variety *Gloire de Lormine* must on no account be omitted from any list of varieties suitable for suspended baskets, as in this way it succeeds perfectly, and forms a very beautiful object, which remark applies to it with equal force when grown in pots.

In thus enumerating some of the most desirable Begonias for hanging baskets, a few words may be added as to the best means of

CULTIVATION.—In the first place, it is very essential that the basket be thoroughly lined, as if this is not done properly it will be a source of trouble throughout the season. Good, flaky Moss is one of the best materials we have; indeed, for small baskets it is absolutely necessary, but for large ones thin closely-woven turves are very good. They should be placed with the Grass side outwards, and arranged so closely as to prevent the soil dropping through, thus leaving a basin-shaped space for planting. The reason that Moss is preferable to turves for small baskets is it does not occupy so much space, thus allowing as great an amount of room as possible for the roots. In planting, equal parts of loam and peat form a very suitable compost, and it should be of a fairly rough, fibrous nature, as in this state it is much less likely to be washed away in watering than if fine. To facilitate watering, the soil must be kept a little below the lining of the basket. As the plants develop and the roots take possession of the compost, a stimulant in the shape of some of the many artificial manures, or that prepared from cow or sheep droppings, must be given about every fortnight. One caution to be particularly observed in the case of plants growing in hanging baskets is, that from their position they naturally dry sooner than if kept in pots; hence it is very necessary to see that they do not suffer from want of water.

T.

NOTES AND REPLIES.

Echinopsis Eyriesii and *E. oxygona*.—I shall be very much obliged if you will tell me whether I ought to remove the young bulbs which form on *Echinopsis Eyriesii* and *Echinopsis oxygona*? I am told that they weaken the parent bulb, and so prevent its flowering. Should they be taken off at any time of the year?—GERRARD.

[We can scarcely understand your question in reference to the formation of bulbs on *Echinopsis Eyriesii* and *E. oxygona*. If on the body of the plant, the objects that you take for bulbs may be flower-buds, we should also have suggested or fruits, except that from your note it would appear that the plants have not flowered. Offsets are so sparingly produced that we do not think you can refer to them, but if you do the present is a good time to take them off and pot singly. To flower these *Echinopsis* in a satisfactory manner they need full exposure to the sun at all seasons.]

Zonal Pelargonium Fire Dragon.—This is a distinct new break, the blooms being deep scarlet in colour and double, with ragged star-shaped tips, which give the flowers a lighter and more elegant appearance than is to be found in ordinary varieties. For all kinds of cut-flower work it will be found useful. I

URBANA-CHAMPAIGN

In making a selection for the purpose, that

A fine Begonia for hanging-baskets, *B. glaucophylla*, in Messrs. Laing's nursery at Forest Hill. From a photograph by G. A. Champion.

just alluded to is one of the very best. The general aspect of the plant is so well shown in the accompanying illustration that nothing further need be said, except that the colour of the flowers is of a pleasing rosy-red when fully expanded, but in the bud state they present a mottled or variegated appearance. From April or May onwards for three months or more a display is kept up. Even when out of bloom it is decidedly ornamental, the leaves being of a pleasing glaucous green, with the colored veins, the entire leaf being when young suffi-

quite a yard across. Being fully exposed to the sun, the flowers and rosy tint of the young leaves acquired a depth of colouring which is not to be found in plants grown in a shaded position. Of course, such a huge mass as this requires a good deal of attention in the matter of water during hot weather. This Begonia is readily increased by cuttings of the growing shoots, taken off at a length of 4 inches to 6 inches, put into pots of sandy soil, and covered with a bell-glass or close propagating case, any time during the spring or early

believe it is a sport from *Raspail*. At any rate, it has a similar habit of growth and is equally free blooming. Market growers should note it, as it is likely to find a ready sale, and amateurs should possess it, being something out of the common and in itself choice.—H.

Cassia corymbosa is an old inhabitant of our gardens, and a showy plant when laden with its numerous terminal heads of golden-yellow flowers at the end of June or early the following month. To do it justice it requires planting out against a pillar or rafter, and treated somewhat like the Grape-Vine as regards pruning, which should be done in early winter. Good loam, with a dash of peat and half-decayed leaf-soil, will grow it satisfactorily. Plenty of space must be given the plant, as the laterals spread out and grow a good length before flowering. It may also be grown well in pots. Cuttings taken with a heel of old wood unsharpened when 3 inches or 4 inches in length, and dibbled in in a shady corner under glass and kept moist, soon form roots, when they may be placed in 3-inch pots, and when established stood outdoors to ripen the wood. Such plants will in late summer, if not pinched, carry a nice head of bloom. This plant has proved hardy in Devon and Cornwall, but with me it gets cut down level with the soil each winter, owing to its late starting into growth in spring. The wood does not get fully ripened to withstand much frost. I am trying it in a more exposed position this year, though full south here I think it may ripen its wood better than in a sheltered nook facing south-east. Except in the mildest parts of England it should have a mat placed over it during severe spells of frost, removing this in mild weather. It would be wise also to protect the young growth in spring during much frost or cold, cutting winds.—J. M. B.

Streptosolen (Browallia) Jamesoni.

—As a climber this plant is not nearly so often met with as it deserves, for in a greenhouse that does not fall much below 40 degs. during winter it will be in full bloom by the middle of April, the orange-coloured flowers being quite a feature for six or eight weeks. When it has passed out of flower it should be spurred hard back and encouraged to make an early growth, so that the new wood may be thoroughly ripened by the end of summer, as all depends upon this maturation of wood whether it flowers well or not the following season. Thinning of the shoots when an inch in length, as in the case of *Bougainvillea glabra*, must not be neglected or a mass of flowerless shoots will be the result. It is of no use planting this in dark corners far from the glass, as it requires all the light possible and should be within a foot of the glass roof to get the best results. I have tried it outdoors in summer, but with me it did not prove a success, as it grew far too freely and gave little or no flower. During the resting period in winter the plant should not be over-watered. It is deciduous with me, though generally spoken of as an evergreen. Cuttings dibbled in when about 3 inches long in July soon root if placed in a shady corner and kept fairly moist without a bell-glass over them. Pot them up when rooted, and place outdoors as soon as established so that the growth gets well ripened by autumn. These, if left unpruned, will each carry a rich head of bloom towards May or June. The after treatment is the same as that for planted-out specimens, with the exception of repotting when nicely started into growth. Plants in borders should have a top-dressing annually in July, using a little artificial manure in the soil, which should be principally loam with a little leaf-soil and sand.—J. M. B.

Photographs of Gardens, Plants, or Trees.—We offer each week a copy of the latest edition of the "English Flower Garden" for the best photograph of a garden or any of its contents, indoors or outdoors, sent to us in any one week. Second prize, Half n Guinea.

The Prize Winners this week are: 1, Mr. S. W. Fitzherbert, Bryndart, Kingswear, Devon, for Arum Lilies at Trellisick; 2, Miss Gertrude Hammersley, The Close, Salisbury, for *Dendrobium speciosum* and *E. J. Fern* in an Australian garden.

OUTDOOR PLANTS

FINE SPRING FLOWERS.

There is just now at Forde Abbey a very extensive and beautiful show of border Polyantheses, and it was to me recently a pleasure to go over them and mark those which I thought should be regarded as the best. Certainly, whilst all were remarkably showy, many were of superior excellence. There was a white, for instance, but one of many, yet the finest without exception I have ever seen. Also, there was a beautiful almost pure yellow, one out of many also which practically had no eye, as the ground colour suffused the whole flower. I had never seen one such before. In other colours, also, were other superb varieties, and the seed of these will be specially saved for next autumn sowing. Mr. Crook's practice, and it is much the best, is to sow the season's seed in August, wintering the plants in the boxes in which sown in any cold-house or frame, then planting out on north borders in April. The plants then become very fine ones by the following winter. I saw various strains of Polyantheses when in the west of England, but none so fine as is the Forde Abbey strain.

When in Exeter market whilst in the west I saw large plants offered very cheaply of an almost giant-flowered strain of Auriculas. Plants of these were obtained, and have also been planted to create both stock and seed at Forde, and it is to be hoped with good results. It is to be sincerely wished that the same attention which has been given to Polyantheses for spring flowering should also be given to border Auriculas. I noticed that these plants did remarkably well at Sherborne Castle, where there were scores of strong clumps; but, so far as I saw, there were not amongst them the bright, effective lines in the flower which are so desirable. What a fine field do these hardy plants offer to an earnest and patient worker.

There are other beautiful hardy spring flowers than these named, and Pansies rank high amongst them. There cannot be any finer flowered strain anywhere than is just now sent in by thousands of plants daily to the London markets in boxes—flowers of great size, good substance, and most superbly coloured. With such a grand strain naming Fancy Pansies seems an absurdity. A. D.

GROWING LILIUMS.

I SHOULD like to grow a collection of choice Lilies. My garden is very open, no shade, and exposed to strong winds, mostly south-west. The soil is fertile and very deep, but light; you can dig it in half an hour after rain with comfort. *Giadulus* bulbs do splendidly in it, and improve year by year. It is surrounded by walls on east, west, and north, and the house on the south. Can you tell me what kinds would succeed, what special treatment before planting, and what after planting? I do not want to grow any likely to fail if I can help it.—F. J. C., *Aerogavenny*.

[We are quite in sympathy with your desire to grow these plants well, but as failures may arise from a variety of circumstances, we fear you will not be exempt from failure any more than the most experienced of old cultivators. We say this advisedly, inasmuch as the frequently-adopted methods of culture fail in instances where the local conditions may seem identical. The soil you describe is much in your favour, while the "open, exposed" condition is not. The latter may be modified, however, as Lilies do not object to their flower-heads being in the fullest sunlight, provided the base is exempt from undue heat. The best way for a beginner would be to devote a border or borders to the plants in question, planting American plants, conifers, or the like, to serve as shelter, on the one hand, and to afford, on the other, that root companionship now regarded as an important feature in the successful cultivation of Lilies. To this end you may require to set apart at least three different beds or portions according to the needs of the various kinds. Quite a large number, however, will be content with the soil you have, others may require peat and leaf-mould, another set a certain degree of moisture, and a few others a stiffer, almost clay soil. Those that may be grown in the ordinary soil would alone form quite a representative collection, as also give a varied season of flowering; therefore, it may be best if you restrict your earliest attempts to

this portion. These are some of them: *auratum* with its varieties *platyphyllum* and *vittatum*, *bulbiferum*, *chalcidonicum*, that prefers a westerly position and a heavy loam, almost verging on clay or sandy clay; *Martagon* and its varieties; *pyrenaicum*, *pomponium*, *Szovitzianum*, *testaceum*, *umbellatum*, *tigrinum* and its several varieties; the forms of *elegans* or *Thunbergianum* generally, which could be best treated if brought together in the front portion of a border, as nearly all the forms are dwarf-growing. Other useful kinds are *croceum*, *Hansonii*, and *odorum*. Then there is quite a wealth of beauty in the early autumn-flowering *speciosum*, of which *cruciatum*, *rubrum*, *Melpomene*, *Kretzeri*, and *album-novum* are a good set. Not only are these good and showy, but valuable from the gardener's point of view in that they are all amenable to ordinary conditions, and prefer a good deal of cow-manure buried under the bulbs at 6 inches or 9 inches therefrom. If we except the "elegant" varieties, all the others may receive manure in the soil if deeply buried below the bulbs, certainly never within 6 inches of the base of any bulb. The bulbs of the *speciosum* group must be 6 inches below ground at least, and being great surface "stem-rooting" kinds, the surface should be mulched with manure or set with thin, low-growing plants so that the sun does not directly play on the roots near the surface. A good plan in the general arrangement of a border of these plants would be to plant certain flowering shrubs, as *Azalea mollis* and *Andromeda floribunda*, as a groundwork for the taller kinds, or the *Ledums*, *Kalmias*, or even small Hollies, preferably green-leaved kinds. In like manner the dwarf *Daphne cneorum*, the *St. John's Wort*, *Megaseas*, *Saxifraga Walloeci*, *Lenten Roses*, and *Tufted Pansies* may all form suitable groundwork, and provide masses of flowers also in their day. The Lilies would, of course, be first planted, and sufficiently deep that the planting on the surface of the other things could be done. Or with such as the *Lenten Roses* these could be in position and the Lilies go between. Much depends on the size of your garden and your intentions as to expenditure. You can hardly make a good start now, though you may get a supply of sound bulbs of a few kinds as *auratum*. The best planting time is October for some, and for others at intervals to the end of March. Those named are not very expensive.—E. J.]

TREATMENT OF BULBS AFTER BLOOMING.

The time is now fast approaching when the beds at present gay with *Hyacinths*, *Daffodils*, *Tulips*, etc., will have to be cleared to make way for the summer-flowering plants. What to do with the bulbs at such a time is often a vexed question, different people having different opinions of the treatment of such. Some that I am acquainted with dig over the beds with a handfork, and cut off the foliage of the underlying bulbs, then plant their *Geraniums*, etc., over the top of them, never expecting the bulbs to resent this unnatural desolation. This I consider one of the worst practices possible. The plan that I have found to answer best, in conjunction with cheapness, is as follows: As soon as the time arrives when the bulbs have to be replaced by the summer-blooming plants the bulbs are carefully lifted and "heeled in" in rows, in finely sifted ashes, covering to the same depth as when in the bed. This allows the foliage to gradually ripen off, whilst the nutriment contained in the leaves is gradually transferred to the bulbs, which store it up for the following season. When the foliage has died down, and feels to the touch somewhat similar to raffia, the bulbs are ready to be relifted. They should then be cleaned and stored away in some dry place—a shelf in the fruit-room being an ideal spot—until required for planting again in the following autumn. The offsets which accumulate round the parent bulb should be carefully removed and planted in single lines in a reserve bed, and in the course of a season or so they will be ready to play their part in the flower garden. Under the above system I have found *Daffodils* and *Tulips* do equally as well as newly bought ones. *Hyacinths*, I have not found to do so well, as they finally split up into offsets, which would,

I imagine, take a long time to come to flowering size, for which, however, I have neither time nor inclination to wait. H. B. P.

CLEMATIS FLAMMULA.

The picture on this page shows one of the uses to which the fragrant Virgin's Bower (Clematis Flammula) may be put in this country. Perfectly hardy and making a maze of long annual growths, which it is impossible to train methodically, it is admirably adapted for planting at the foot of any structure which it is wished to cover with an informal veil of flower and foliage. In this case we see the terminal pillar of a high wall crowned with its flowering growths, but for rough terraces, pergolas, summer-houses, and arbours it is equally

tree, either evergreen or deciduous, into whose branches it will ascend to a height of 30 feet in an amazingly short time when once established.

Old ruined Elms and Oaks are thus converted from eyesores to objects of beauty, and the starry trails of the Clematis are shown off to best advantage when swaying amid the sombre foliage of an ancient Yew. The yellow-flowered C. graveolens is a summer bloomer, and soon spreads over a large expanse. Its blooms are succeeded in the autumn by feathery seed-vessels, which are quite as effective as the preceding flowers, and suggest the smoke-grey billows of the common Traveller's Joy or Old Man's Beard (C. Vitalba) of our hedgerows and copses. C. Flammula is later in flowering, rarely being at its best before the end of August or

NOTES AND REPLIES.

Treatment of Pansies.—Will you kindly tell me how to treat my Pansies so as to make them continue in bloom through the summer? The seed was sown last year, and the plants are now flowering well. Should they be cut back in June, like *Viola*, in order to secure a second display, and, if so, am I to cut them right back to the root? There are four or five long stems to each plant, with a tuft of leaves and bloom. Should these be entirely removed? I shall be much obliged if you will kindly explain how it should be done?—E. D. H.

[No, Pansies will not submit to the treatment suitable for the Tufted Pansy, as they do not spread at the roots like the Tufted Pansy, and only bloom once, keeping up no succession during the summer. If you want a succession of bloom, you must grow some of the many fine forms of the Tufted Pansy we now have.]

Blight on Lilies of the Valley.—Lady Onslow would be much obliged if the editor could tell her what has caused the blight to her Lilies of the Valley, of which she encloses specimens? Most of the flowers in the beds are spoiled in this manner, but not all. Some overhung by trees have escaped, and some in a higher, colder part of the garden are free from injury. Some of the beds affected are very old and thick with leaves, but some are newer. It happened just the same about three or four years ago, and ever since there are some blighted flowers each year, but last year hardly any.—LADY OSLOW.

[We could not determine from the state of the blooms whether frost or poverty of the soil was mainly responsible for the failure. The flower-buds gave the idea of the frost, but the weakly and very thin leafage bespoke poverty of the soil. Information as to dryness or wetness of the soil would have been helpful, and good foliage—essentially the builder-up of good spikes of bloom—is rarely seen in dry soils, and still more rarely where dryness and poorness go hand in hand. We know of some plantations in Thames-side gardens, much under trees of large size, that produce grand spikes of bloom each spring. These, however, are often within reach of water, and at flood-time immersed for awhile. At such times, too, there is the usual residuum from the overflow—a by no means invaluable asset, inconvenient though the flood may be. In your case we are quite prepared to believe that better results would ensue if replanting of the beds was taken in hand in the coming autumn. Moisture at the root is very necessary, and if to this we add that the Lily of the Valley always delights in very deep and quite rich soil, you have the general requirements in a nutshell. We believe there is not much amiss that cannot be rectified by good culture, and if you can, by water or supplies of liquid-manure, irrigate your plants now—even a sowing of soot well watered in, or soot-water after flowering would do—so much the better for the work of replanting that should be done early in October next. Old plantations should be heavily mulched each winter with manure.]

Planting Snowdrops.—I wish to plant a thick carpet of Snowdrops next autumn under a large Copper Beech in my garden. My soil is light and poor. I thought of digging out a spit of soil where I want to plant the bulbs and putting down a thin layer of clay, which I can obtain near here, then replace the soil above. Would that give the Snowdrops a better chance of doing well? If so, I should put down the clay in good time to give it time to settle before planting the bulbs. Could you suggest any low-growing plant that I could use as a groundwork to come out after the Snowdrops were over?—T. M. D. H.

[The idea of sinking in some clay beneath these bulbs will do quite well, but we suggest, instead of inserting the clay *en bloc*, that you dig more deeply and in irregular patches or drifts, as it were, dig out the original soil, and incorporate the clay with the remainder, and plant the bulbs in this mixture. For the underlay the clay may predominate, using less, or, if you like, none at all in the upper portion. What you also should bear in mind when preparing the positions for the Snowdrops is their preference for deep planting. Far too many make indifferent progress in gardens because planted just under the surface, whereas the growth and all else are much stronger when the bulbs are planted at least 6 inches deep. If the bulbs are quite fresh and sound there need be no fear of success. We have dug up old clumps that must have been nearly three times this depth, while the leaf growth was not far short of the same length. One of the best dwarf plants to follow the Snowdrop is *Anemone pennina*, that makes a nice carpet of leaves and furnishes abundance of its pretty blue flowers quite early in April and through the month of May. Do not crowd this in planting. Single tubers should be inserted 6 inches apart and about 4 inches deep. The effect is very

Clematis Flammula on a pillar. From a photograph by Mrs. Deane, Fairfields, Fareham, Hants.

desirable. Other members of the Clematis family lend themselves effectively to the same usage as suggested for C. Flammula. Clematis balerica or calycina is absolutely hardy in the south-west, and bears its greenish-white flowers, spotted with purple in the interior, as early as the month of February. It is a vigorous grower, and is especially decorative when festooning evergreens, which it readily mounts to the height of 20 feet or more. It is followed a month or so later by the very similar C. cirrhosa, whose flowers are unspotted. Towards the end of May and commencement of June the well-known C. montana flowers, and creates a lovely effect as it drapes wall and tree with an ivory-white mantle of star-flowers. This is a Clematis of especially vigorous habit, and should be allowed to express its characteristic attraction by absolutely untrammelled growth. It is seen at its best when planted at the roots of some old

beginning of September. C. paniculata is not unlike the foregoing, being also sweetly-scented. Its white flowers are alike in shape and in their whiteness, but the petals are of a firmer texture. It follows C. Flammula in its period of blooming, being usually in the zenith of its beauty in October. Clematis coccinea is not adapted for such positions as recommended for those of the same genus already mentioned, but is a beautiful and very uncommon flower. In the best forms the drooping flowers are scarlet, and give the plant an exceptionally bright appearance. It is a native of Texas, and requires warm and light soil. In the colder countries it is often cut down to the ground in winter. When well established it makes growth from 10 feet to 12 feet in length, and flowers for a lengthened period. It is well worth growing by anyone who can give it a sheltered wall.

S. WILKINSON

pretty in or near the Grass, and always admired. Many other dwarf Anemones are also suitable, but this we think the more so in the present instance.]

Using a brick pit (Perplexed).—If you heat your 15 feet long brick pit with a flue of drain pipes, the best course is to fix the flue fairly low down, and have wood slabs placed crosswise over it, through which heat can rise to warm the soil placed on the slabs. The pipes should be fully 6 inches in diameter. For such heating you would need a furnace low down at one end, and a small pipe chimney at the other. If you fixed a small boiler, but with enough length of pipe to run along the front of the pit just under the glass and to return beneath the bed, you would get better results, but the cost might be some £4 to £5. You could, if you like, dispense with such heating, and fill up the pit with well-prepared hot-bed manure to within 12 inches of the top, treading it well, then putting on to that 4 inches of soil, and sowing on it or in pans, pots, or boxes, all sorts of flower seeds, Tomatoes, Cucumbers, Marrows, and many things. But such bottom-heat would not long endure, and then you would have to trust to sun-heat as the summer advanced. To have any good heat from manure, the pit should be fully 4 feet deep inside. An earth floor is best for all purposes. If the top of the pit is properly slanting, and as it faces to the south, you should have ample light, but, of course, all things grown in it should be kept as near the glass as possible. Forcing Rhubarb would need that the roots be put into soil fully 2 feet from the glass. But Rhubarb can commonly be better forced in any warm cellar or dark place, especially if 12 inches thick of warm manure be placed at the bottom. For Cucumbers the soil should be in mounds along the centre of the pit, 12 inches from the glass, two plants being put into a mound under each light.

Late-flowering Tulips.—We are reminded of the value of the May-flowering Tulips in the garden by a gathering of flowers in many colours from Mrs. Bayldon, Oaklands, Dawlish, Devon, these being unsurpassed for a brilliant effect in the garden at this season of the year. The chief thing is to plant the best self-coloured kinds in quantity, for, beautiful as a single bloom of the striped or flaked Tulip may be, it is only the self-coloured species and varieties that give the finest display in the garden. The early-flowering kinds descended from *T. suaveolens* are certainly very useful, but, to our mind, are of less value than the fine late sturdy-growing kinds that open in May. These all spring from *T. Gesneriana*, and, while possessing infinite variety of colour, have the same form and stately habit of the parent. These late Tulips, coming after the Daffodils, are precious garden flowers and not often enough seen. We want more Tulips of the same colours as the florists' forms in self colours, such as White Swan, Bouton d'Or, Golden Eagle (yellow, edged red), and Golden Beauty (self yellow). Among the wild Tulips, too, there are also many beautiful kinds, such as *T. elegans*, *T. Didieri* (with bright red flowers, having black blotches inside at the base), *T. fulgens* (flowers rich crimson on tall stems), *T. Kaufmanniana*, *T. Kolpakowskyana*, *T. macrosepa*, *T. retroflexa* (pure yellow), and *T. vitellina*, of a lovely yellow tint.

Doronicum plantagineum (Leopard's Bane).—I have some fine pieces of this spring-flowering hardy plant, which, together with the pretty *Alchemilla*, provide a con-

tinuous supply of yellow blossoms when the Daffodils are past their best. My plants are now three years old, and, as may be readily imagined, they make an imposing display. They are somewhat coarse in their style of growth, and unless given plenty of room quickly spoil other less vigorous plants near them. The cold and cutting easterly winds which have lately prevailed bleached and curled the outer ends of the somewhat narrow florets, but as there are so many other buds to follow, those with the blenish just referred to are better cut off. It is a plant suitable for almost any position, and succeeds well in town gardens.—W. V. T.

ST. BRIGID ANEMONES.

THESE brilliant flowers are the result of careful selection from the single flowered French or Poppy Anemone, *A. coronaria*, and were originated by an Irish lady about thirty years ago at a place called Nurree, or the Oratory, in the county of Kildare. It was in Kildare under an Oak tree that St. Brigid began her Christian missions in the fifth century, hence the popular name adopted for these flowers. The modern St. Brigid treated these flowers as early annuals, sowing the seed every spring in February or March, and rigidly weeding out poor flowers so that the next season's seed

St. Brigid Anemones flowering in early spring at Geashill.

might be better than the last, and in this way the strain was continually improved by selection and good cultivation alone. The seed was sown directly in the beds in which it was intended to bloom. The seedlings were thinned out to 6 inches apart, any blanks in the beds being filled up with the best of those removed in the thinning out. The beds themselves were dug two spits deep, the top spit being thrown out in the process, and plenty of old well-rotten cow-manure was added before the last 6 inches of soil were filled in. The seed should be rubbed up in sand or dry, fine earth, so as to separate it before sowing, and then scattered thinly broadcast, or sown in lines over the bed. If the weather is very dry the seed may be covered with mats or canvas until it begins to grow, when they should be at once removed, and, if possible, during showery weather.

Thinning may be carried out when the seedlings are 1½ inches to 2 inches in height, and the young plants may, if desired, be replanted at 6 inches apart in other deeply dug and well-manured beds. It should not be forgotten that these Anemones are essentially flowers of the sun, and do best in an open and fully exposed position, provided they are sheltered from high winds and gales. Seed sown in February often produces plants that commence flowering in October the same year, and even if checked by winter frosts and snow, they again begin flowering in February and March, reaching their fullest flush of beauty in April and May.

We have seen them in full beauty all through the winter in warm and sheltered sunny nooks near to the sea both in England and Ireland, and by picking the buds and opening blooms they were most welcome and long enduring as used for indoor floral decorations. At the Daffodil show held at Birmingham on April 24 considerable excitement was caused by a large and most effectively-arranged stand of these flowers from Geashill, in the King's County. They were large and long-stalked blooms, mostly semi-double, and of all colours from white and flesh colour, through all shades of bluish-lilac, purple, red, and scarlet, to other shades verging on blood colour and crimson. As shown in water under a glass, the hot sunshine that made some of the Narcissi look faint and wan only seemed to infuse new life and brilliancy of colouring into these gorgeous Windflowers, thus showing what admirable cut-flowers they really are, or may be. They are grown by the acre at Geashill for trade purposes, but even in the smallest of gardens they may be readily raised and grown for the sake of their dense carpet of fresh green Parsley-like leaves, thick set in spring with their buds and flowers.

Some growers purchase roots or tubers and plant them with good results, especially on stiff, holding, or loamy soils; but, as a rule, it is better to sow the seed as above directed, in the beds where they are to grow and bloom. At present, a packet of seed yields all colours, but in the future we hope that tubers of the finest colours and shades may be isolated and grown on for seed, so that, as in Primrose, Cyclamen, and other florists' flowers, the finest shades may become fixed by inter-crossing so as to come true from seed. All the Windflowers, or Anemones, are very beautiful, but none are quite so Poppy-like, so beautiful and effective, or so easily grown in large groups and masses as are those of the St. Brigid strain.—Field.

—The display of the varieties of the Poppy Anemone (*A. coronaria*) the other day at the Drill Hall doubtless very largely whetted the appetites of visitors to have tubers or seed of these beautiful things, and thus secure stock. It is probable that English purchasers would do best to secure tubers or roots next autumn. They should, if put out in good soil and where the flowers get ample light without being exposed to harsh winds, give a beautiful mass of flowers. But it is doubtful whether, if the position be dry and arid, the tubers, whether lifted and replanted in fresh ground or allowed to remain in the ground, would give anything like that fine mass of bloom the next year they give in Ireland, or would furnish the first year of planting. Anemone leafage is very susceptible to injury by sulphurous fogs and dry atmospheres. Probably the worst enemy is fog, as it is most difficult to grow them in the metropolitan fog area. That was not always the case. I was some years ago able to have the French Poppy Anemones raised from seed in most beautiful form in West Middlesex, but a few years later the demon fog rendered generous growth practically impossible. Still, there can be little doubt that the wondrously fine flowers and good leafage seen on the Irish plants are largely due to the relative moisture of the climate. By its aid the leafage not only becomes robust, but it can fully mature, and hence fine flower-producing tubers are formed. Wherever in England the situation is relatively moist, yet sheltered, Crown Anemones should do as well as in Ireland. If raised from seed, sow at once in shallow pans or boxes or under handlights in sandy soil.—A. D.

Gladioli.—It is, I think, a popular belief that if Gladioli corms are left in the ground during the winter, the probability is that they will perish, and I have always acted up to this, removing mine from the borders in October, replanting them in April. On putting them in the other week I came across a number of corms in a bed, which had been overlooked. They were growing well, and did not appear to be any the worse for being in the ground all winter. I should hesitate in recommending that the corms be left in the soil in a general way, as probably some of them, the older ones especially, might rot, but it is interesting to note that there are no exceptions to some of our

rules which many have come to regard as of the utmost importance. The soil where the corns wintered is a light, loamy one.—W. F., Derby.

ORCHIDS.

OPEN-AIR ORCHIDS AND FERNS.

The illustration shows *Dendrobium speciosum* and one of the larger Elk's-horn Ferns (*Platycerium*) growing on a tree-trunk in an Australian garden. In tropical and sub-tropical countries many of the rarest of Orchids are thus grown, and are often very beautiful and not a little surprising to those who know these things only under a glass roof in northern gardens. I shall never forget the delight with which I saw *Allamandas*, *Stephanotis*, and *Xepenthes* luxuriating in the open-air beds and borders in the Botanical Gardens at Singapore, and the rustle of feathery Palm-leaves as they tossed and trembled in the air high overhead, each from silhouetted against a cloudless sky. In one of the more distant flower beds I saw a mass of what looked like a tall clump of Sweet Pea, but there seemed a difference, and on going closer I found it was a

very common, but I never saw so many fine specimens thus naturally grown as in the extensive and beautiful orchard or fruit garden made by Sir Hugh Low when he was Colonial Secretary at Labuan many years ago. Our residents in the colonies abroad, both in the east as in the west, have often great opportunities for real sub-tropical gardening, and yet we too often find a mere repetition of gardening as carried out at home. The English copy the bedding out in the London parks, and the French try to repeat the effects of the Luxemburg garden, or at least those of the Parc Monceau, forgetful or neglectful of what noble gardens could be made of the best of native things. The illustration of the Rock Lily of Eastern Australia, supported by the Elk's-horn Ferns, tells its own tale, and the style of arrangement or grouping might now and then be made use of in our Orchid-houses here at home. F. W. BRIDGEMAN.

GARDEN PESTS AND FRIENDS.

Fungus on Pelargonium leaves (J. Thoms).—Your Geranium leaves are attacked by a fungus belonging probably to the genus *Cercospora*. Pick off and burn the infested leaves, look well after the ventilation, not

very expensive. The best is published in nine octavo volumes, costing about £1 apiece, by the Ray Society. There is another, which is far inferior, which costs about £3, the name of which I cannot remember, but I could find out if you wish to know it. It is impossible to name caterpillars from descriptions.—G. S. S.]

Pear leaf blister mite.—I shall be much obliged if you will tell me in GARDENING what the spots are on enclosed Pear leaves?—IRETON.

[The leaves of your Pear-tree are infested by the Pear leaf blister mite (*Eriophyes pyri*), which burrows into the leaves and causes the spots, the colour of which, I suppose, is caused by the action of the mites cutting off the supply of nutriment to cells of the leaves under which they are feeding, which become discoloured much the same as they do in the autumn. If your tree is a small one, so as to render it possible to pick off the affected leaves, I should do so at once, and immediately burn them, and then spray the tree with a solution of paraffin emulsion; the spray should be applied to both surfaces of the leaves. In the winter it would be well to spray the trees again, as this mite passes the winter among the outer bracts of the buds; or the tree might be sprayed with a caustic alkali wash any time after the leaves have fallen and before the buds show any signs of opening in the spring. The mites are very small, white, narrow creatures, which, as a rule, are quite invisible without a magnifying-glass.—G. S. S.]

VEGETABLES.

SECURING THE STEMS OF ASPARAGUS.

This is not practised so often as it should be, and yet it should be looked upon as one of the most important details connected therewith. One might go into numbers of gardens during the summer months and find the Asparagus quarters somewhat neglected, the tops bending over. Even if not partially broken through, they are in such a condition that they cannot perform their proper functions—viz., storing the roots with nutriment for another season's crop. Considering that Asparagus is one of the most important of vegetables, it is surprising that it should so often be left, as it were, to take care of itself, and yet when the season comes round the crop is eagerly looked for; in fact, when vegetables are scarce it has to prove a veritable sheet anchor. Being truly herbaceous, it is all the more desirable that the growth be well cared for. No doubt there are instances of good Asparagus being produced annually where no securing of the stems is practised, but these are more the exception than the rule, and position must be greatly in their favour, being in this respect well sheltered from wind-storms. I have known seasons when the tops would have been quite free from injury until the summer was far advanced, or, indeed, well into autumn before any violent storms have occurred, but we can never tell what may happen, and it is always best to be well prepared.

The process of staking is not at all difficult, and the time it takes is hardly worth mentioning. Where the crowns are very strong and planted some distance apart, these should have a stake placed to them individually, taking care that the stakes are not thrust into the centres of the crowns. In other cases stout stakes may be placed at each end of the lines, and a few others intermediate down the rows, or according to the distance, these being for the support of long and slender rods, and to which the stems must be tied. Another advantage, besides the injury from wind-waving, is that by being tied upright, direct sunshine and light reach the bottom of the stems. By allowing the tops to sprawl all over the beds the surface is not so apt to dry quickly, but where the beds are properly mulched this is not likely to happen. Not only established beds, but seedlings should be seen to. P.

Mulching early Peas.—As a rule the first early Peas are planted in the warmest corner of the garden and in a warm soil, the object being to secure a few pickings as quickly as possible. This being so, it is sometimes necessary to mulch and even to water to avoid a sudden collapse of the crop. Chelsea Gem is slow to fulfil these promises well.

Dendrobium speciosum and Elk's-horn Fern in an Australian garden. From a photograph sent by Miss G. Hammenley, Salisbury.

splendid mass of *Vanda teres* growing to the top of Teak wood stakes 8 feet high, all the topmost portion a mass of soft white and ruby-tinted flowers. So, also, in the tropic island of Labuan, Orchids such as *Vandas*, *Phalaenopsis*, and many other epiphytal kinds, grow and flower most luxuriantly on the cultivated Orange-trees. These plants are often in the first instance established on Palm stems or in old husks of the Cocoa-nut, and are then placed in the forks of the branches or lashed to the trunk or main branches with rottan canes, and if this is done just as the rainy season sets in, they soon spread and fix themselves firmly to the smooth, living bark of the trees by their thong-like, aerial roots. The approachers to some suburban bungalows in Singapore are planted with great masses of *Gramatophyllum speciosum*, having thick Reed-like stems 8 feet or 10 feet high, so that visitors really walk up to the floor through an avenue of this gigantic Orchid. To walk out in the early morning or in the cool of the day, and wander through an orchard of Oranges, Pomeles, Citrons, and Limes, interspersed here and there with trees of the Mango, the Mangosteen, Durian, Jack-fruit, and Litchies, is an experience not easily forgotten. In some of these tropical fruit orchards the Orchids and Elk's-horn Ferns are

keeping the plants too closely packed together, and spray every 10 days or so while there are any signs of the disease with "Bordeaux mixture."—G. S. S.

Insect pests.—Can you give me the name of an illustrated book that will enable me to identify insect pests? In my orchard I have small green caterpillars (larva of winter moth), small brown caterpillars, and many leaves infested with a small grub about the size of a pin's head and of a bluish-grey colour.—J. C. PRADIE.

[I am afraid that there is no book which would enable you to identify all insect pests. There are several books on the subject, dealing, however, more particularly with those which affect agricultural crops. Among the best are "Manual of Injurious Insects," by Miss Ormerod, an octavo book, freely illustrated with woodcuts, published at 5s.; Curtis' "Fam. Insects," a quarto book, illustrated with woodcuts and coloured plates, the latter add largely to the cost of the work, which is 16s. There are some very valuable leaflets issued by the Board of Agriculture, and which will be sent free to anyone asking for them, which are well worth your getting. Apply to the Secretary, Board of Agriculture, 4, Whitehall-place, London, S.W. You need not stamp your letter of application. The only books which would enable you to name any caterpillars you might meet with (the books already alluded to will enable you to identify many of

Before putting on the mulch of short manure give a sprinkling of artificial manure; this will be washed down to the roots by occasional waterings and enable the pods to swell off. If this assistance is denied the crop in dry windy weather the secondary blooms sometimes fail to set at all. If William the First, Exonian, or any of the second earlies show a tendency to grow instead of to flower, they may be urged into fertility by pinching out the leading growths, and when well furnished with bloom may be assisted in the same way as advised for the earlier crops.

GARDEN WORK.

Conservatory.—The hard-wooded plants which have completed their flowering should be collected together and placed in a house by themselves, where growth can be made under suitable conditions, and any pruning or pinching required can be given from time to time to keep the plants symmetrical. Repotting, if required, should not be delayed. Those who have fine specimens and wish to keep them so will not allow them to remain in the conservatory so long, as the usual kind of house is not the best for hard-wooded plants, though in careful hands they are safe enough for a time; but Azaleas want the syringe daily when growing, and this cannot be done where the house is full of flowering plants. The flowering of the Acacias is over, and the plants should have been pruned back. Winter-flowering Heaths also should be put into condition for growth, and repotted if necessary. It is of no use attempting to grow Heaths in anything but the best of fibrous peat and clean silver-sand. Erica propendens is one of the prettiest early-flowering Heaths, and is not difficult to grow—at least, those who can grow the winter-flowering varieties will succeed with propendens. Good specimens of Erica Cavendishi and ventricosa are very attractive now, and, if placed in a light position, will last in perfection some time in the conservatory without injury. With such plants the watering and the ventilation are the chief things to be considered. The house will be very bright now with Pelargoniums (including Zonals), Fuchsias, Hydrangeas, Lilies of various kinds, Tree-Carnations, Roses, etc., including a few odds of novelties which are not in sufficient stock to make any great display. For instance, just now a little group of early-flowering Gloxinias, Himantophyllums, and Streptocarpuses, set off with a mixture of Maiden-hair and other Ferns, is pleasant to look upon. Fires have been discontinued, and a little ventilation will be left on all night along the ridge. The watering may still be done in the morning, but many things will want another look round about midday. In very hot weather it may be desirable to damp floors once or twice during the day to keep down the heat. Shade will be necessary if very bright.

Stove.—Fine-foliaged plants, including Caladiums, Dracaenas, Crotons, Marantas, etc., will be very interesting now, as the new growth of most things in this way is so clear and bright. Suckers may be taken from Pandanus Veitchii when they can be obtained. This makes a good specimen for exhibition, and is easily grown. Small plants of good colour are sometimes used for table decoration, having a striking appearance as centre plants, but they are not generally popular—at least, we have not found them so, as the hooked spurs on the leaves are always catching things near them. The most popular leaf plants are Caladium argyrites, Cocos Palms, red or golden-leaved Dracaenas, and the long, narrow-leaved Crotons. What is generally required for the work is not bulk or weight of foliage, but light, graceful-foliaged plants. The variegated Cyperus is very well for a change, and rather small plants of the gold and silver Ferns are useful when a distinct feature is required. A good many plants are required for table work in large country houses in the autumn and winter, for which provision should be made now. Smilax and Asparagus Sprengeri and plumosus are sure to be wanted, and these cannot be improvised on the spur of the moment.

Orchard-house.—Top dress trees in pots with rich compost. At the present stage trees

in pots will take a good deal of nourishment. The best way is by giving top-dressings, supplementing where necessary with liquid-manure. The final thinning of the fruit should be given soon. Quantity when excessive means poor quality. Use the syringe daily in bright weather twice a day, and without overdoing it see that no trees suffer from dryness at the root. Ventilate very freely when the weather is warm, but keep out cold north or east winds without unduly raising the temperature. Leave a little air on all night in warm weather.

Ripening fruit.—When any fruit is approaching the ripening or finishing stage, diminish the supply of water—not to permit the roots to get dust-dry, but if the roots are deluged when the fruits are finishing the flavour will be spoiled. This refers especially to Melons, Peaches, Pines, and in a less degree to Grapes. Peaches and Melons soon show by the flavour the bad effects of an influx of water at the roots at the finish. Deficient ventilation also has a bad effect upon flavour when fruits are ripening.

Sublateral growth on Vines.—Every Grape-grower who has studied the constitution of his Vines will know how to manage the sublaterals in the various stages of the Vine's progress. Sometimes when the crop is taking its last swelling, it is good policy to permit a little more freedom to the lateral growth, especially in such kinds as Madresfield Court Muscat, which under certain conditions shows a tendency to crack the berries. Dryness at the root in the early stages, very close pinching of the young growth by reducing the breadth of foliage, may have a tendency to cause cracking, or, in some cases, shanking is produced by it. There should be plenty of foliage, but every leaf should have room for full development. With the advent of warmer weather less fire-heat will be required, though in our changeable climate the fireman must always be prepared to turn on the heat.

Window gardening.—Window-boxes are now being filled, and special efforts are made to have a gay scene early. There is a big demand for red, white, and blue flowers. I daily come into contact with a good many people, and all are running upon the same ideas of decorating with the National colours. I have no sympathy with crowns and monograms worked out in flowers. They are usually dismal failures, and belong more to the gasfitter or electrical engineer than the gardener. Have the windows bright certainly, and if there are any well-flowered plants of Agapanthus umbellatus in tubs, stand them about the lawn or in the forecourt. Good bushy plants of Hydrangeas in tubs also will help to brighten up the front garden. A mass of Salvia patens in a rustic basket surrounded by white Ivy Geraniums is attractive. Those who want scarlet will find abundant material in Geraniums. Fuchsias are always graceful things and easily grown.

Outdoor garden.—The season is very backward; even the usual spring bedding has hardly reached its best. So, where the tender bedders follow spring flowers, the tender things must be well looked after to prevent a check being given. There is a great demand this Coronation year for red, white, and blue flowers, and most of the scarlet Geraniums, white Marguerites, and blue Lobelias will be used up. Scarlet Lobelia Queen Victoria, blue Salvia patens, and white Verbenas, pegged down, will give the national colours in a somewhat different form, perhaps a little more interesting than the usual Geraniums, etc. There will be a severe struggle with insects this season. They always come in shoals with the east wind, or, rather, the east wind checks the growth and prepares the way for the green-fly. One of the best insecticides for flies, green or black, is Tobacco powder. It is always ready, can be easily applied, has a deadly effect, and is cheaper than washes; but do not wait till the leaves are curled. Maggots in the foliage of Roses must be crushed between the finger and thumb. Place the stakes to Carnations in good time. The same remark applies to Dahlias and Hollyhocks, and have the stakes strong enough to resist a gale of wind. What a lovely family the border Pinks are, and how early they grow a good collection! They are worthy

of more attention. Hardy annuals should be thinned in good time, as a plant weakened by overcrowding never does its best. The Ever-lasting Peas are among the best plants for planting against small trees to cover the stems, such as Apples, Thorns, etc. Keep the hoe going. A loose surface saves watering.

Fruit garden.—The early blossoms of Strawberries have suffered from the frost, and in some exposed, low-lying situations the crop will be a smaller one than was at one time hoped. Bush fruits also will probably be affected by the same cause, though it is probably premature yet to give a final estimation, as very often results come out better than expected. The principal work now is fighting insects, and this must be followed up till the trees have been cleared of their enemies. The copious rains which have recently fallen were much needed, and will have a beneficial effect. All spare frames may now be filled with Cucumbers and Melons. There must be root warmth to give the plants a start, especially for Melons, as a cold root-run generally leads to disease, canker in Melons being generally induced by a low temperature. If canker appears on the main stems of Melons, attack it by covering the affected parts with quicklime, changing it often till the disease is checked. If taken in time the plants will be enabled to ripen the crop. I think it is important that seeds should be saved from healthy plants only, and where possible growers should save their own seed. In earthing up Melons use rather heavy loam slightly enriched with bone-meal.

Vegetable garden.—Turnips may be sown in larger patches now. Snowball and Veitch's Red Globe are good varieties. There is not likely to be too many Peas—Autocrat, Ne Plus Ultra, Walker's Perpetual, and Daniel's Matchless are good varieties. Early sown Leeks may go into shallow trenches enriched with rotten manure or manurial compost. The preparation of Celery trenches will be in progress now, and here also it is an advantage, if the manure is worked in, to include some of the old vegetable waste and charred refuse of the garden. There is yet time to sow Scarlet Runners for succession. We generally plant the white-seeded Runner at this season. Veitch's Climbing French Bean is a profitable variety. It is important that all Beans and Peas should be gathered as soon as fit for use. We have often had a good lot second crop from Ne Plus Ultra and other Peas when the plants have not been exhausted by leaving the pods or any part of them on the plants to get old, and the same remark applies to Beans. Even Longpod and Windsor have borne a second crop not much inferior to the first when the pods have been gathered young and the stems shortened, and a mulch of manure given. Early Horn Carrots to be drawn young may be sown up to the end of June, and Parsley, from a June sowing, always comes in useful.

E. HORDAY.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

June 2nd.—The planting of flower-beds and borders is in full swing, and other work will for the time being have to give place to it. Planted out New Zealand Spinach which has been raised in heat. We find this very useful. We give it a warm, sunny situation. Placed stakes to Carnations and Pinks of the choice kinds. When Pinks grow into a mass, of course stakes are not required, as the flowers support each other. Planted out Dahlias and placed stakes to them, and supported each plant with a tie.

June 3rd.—Prepared trenches for Celery. Planted Lettuces on the ridges between the rows. French Beans are being gathered from pots now. All plants in pots have been removed from houses, as they become dangerous from their liability to red-spider. Liquid-manure is given to Strawberries in pots in cool-houses. This is the last crop under glass. Plants outside on warm border have set fruit. Fortunately these were sheltered with tiffany and escaped frost. Attention is being given to spray fruit-trees to clear them of insects.

June 4th.—The hoe is used freely among early Potatoes now through the ground.

Staking and tying Tomatoes in cold-house, and rubbing off side-shoots. Tomatoes for planting outside are hardening in cold-pits with lights off all day. We have planted out a few Vegetable Marrows and ridge Cucumbers under handlights, and others are waiting in cold-pits for settled weather to make it safe for planting. Fresh manure is not used for these plants. A little good compost is placed in the hole with each plant.

June 5th.—Placed stakes to Hollyhocks and Madonna Lilies; the last are strong clumps, and the soil being rather gritty, a mulch of manure has been placed among the plants. Hollyhocks, Dahlias, and Phloxes are treated in the same way. Potted off a lot of seedling Gloxinias and Streptocarpuses. Moved Cyclamens to cold-pit; shall soon begin to shift into 3-inch pots. This refers to last season's seedlings only. Older bulbs are planted out in cold, shady pit under north wall. We have given over drying off Cyclamen corms; there are fewer losses in consequence.

June 6th.—Placed some Orchids just beginning to grow into new baskets. A few *Oncidium*s and *Dendrobis* have been attached to new blocks. Shifted on various *Neprolepis-Ferns*. Several strong plants of *Neprolepis exaltata* and *Polypodium aureum* have been placed in wire baskets. Several baskets have been filled with *Achimenes*, and will be kept in a warm, shady house for the present. Planted early Leeks in trenches. Pricked out more late Celery-plants, Major Clarke's Solid Red being a favourite.

June 7th.—Planted out Stocks and Asters in reserve beds for cutting. Asters are especially useful to us. Planted out more Brussels Sprouts and Veitch's Self-protecting Autumn Broccoli. A good breadth of Autumn Giant Cauliflower has also been planted. A good many of the Plums have fallen from the severity of the weather, but there will be a crop, and the fruit on some trees may require thinning. It pays to thin the best dessert Plums. Looked over Roses to remove suckers and destroy insects. We find Tobacco-powder useful for green-fly.

BIRDS.

Food for Canaries (Silver Plated).—The staple food should be Canary-seed. To this should be added, in similar quantities, the smaller kind of Rape, of a purple or reddish hue. The large black Rape is harmful, especially to young birds. A little white Millet-seed may be given occasionally, while Linseed is found very useful in helping these birds over their molting; indeed, a little may be given at any time. Inga-seed must be carefully avoided as it causes derangement of the liver in a very short time. Hemp may be given, but it must be used sparingly, as it is very heating, and of a fattening nature. The small kind of Hemp is the best, and should be of a bright grey colour. You were not judicious in giving your bird so much Apple; a little hit now and then, however, will do no harm. The green food should consist of Groundsel, Chickweed, Dandelion, and Lettuce, but should be given in small quantities, and fresh, although not immediately after being gathered. It is well to remove from the cage any not consumed within a couple of hours or so, as stale green food is harmful. A rusty nail in the drinking water provides a mild tonic, and keeps caged-birds in health.—S. S. G.

POULTRY.

Food for chickens and ducklings (H. A. T.).—The best food for chickens after first few meals of hard-beiled egg and bread-crumbs is one part of Barley-meal and two parts of coarse Oatmeal, mixed with milk or water to a crumbly paste. In a few days they may have crushed Wheat, grits, or bruised Oats, while a little lean, undordone meat, minced fine, may be given daily until the chickens are about three weeks old. At first they should be fed every two hours, and then the number of meals gradually reduced to four or five. If there is no Grass now, or if the weather is not favourable, some Grass or other

vegetable food, minced small, may be given. For the first three weeks ducklings may have well-toiled Rice and groats mixed, which, when thoroughly drained, should have as much Barley-meal worked into it as will make it into a dry, crumbly mass. Chopped Leek-tops, Onions, or Lettuce will keep the ducklings in good health, and a little meat in the shape of boiled liver, minced, is very beneficial. For the first ten days they should not be allowed to go near water, but sufficient must, of course, be given for drinking. They should be cooped in a dry situation free from draughts. At the end of three weeks they may be less studied in their diet; in fact, they will at that age consume almost anything in the shape of Corn, meal, garden refuse, and scraps. To fatten ducks they should have as much food as they will eat, crushed Oats and Pea-meal being the standard. Green food, of which nothing is better than Lettuces, may be given abundantly. Boiled roots mixed with Barley-meal and a little milk added are excellent during fattening. If well fed they should be fat in eight or ten weeks. It is impossible to say which is "the best incubator" out of the large number there are in the market. Of American machines alone there are at least thirty different makes.—S. S. G.

LAW AND CUSTOM.

Trespassing cats.—What steps am I justified in taking to protect myself against the nuisance of neighbour's cats straying continually into my garden?—S. C. R. (I think your only practicable remedy is to chase them out, although, if the cats do actual damage, and you request your neighbour to prevent a recurrence of the trespass, and he ignores your request, you may, on proof of the facts, recover damages in the county court.—K. C. T.)

Tenant continuing in occupation after expiration of lease.—I held a piece of land on a lease for a term expiring on January 6, 1902, but am remaining in occupation without any new agreement. By the old lease it was at liberty to remove and take away everything on quitting. What is my present position? I am a working gardener, and have erected greenhouses, frames, and shed, and planted trees and shrubs, etc.—M.

[I suppose you are remaining in occupation under an informal arrangement, and that there is no question as to any wrongful holding over. If this be so, as soon as you pay any rent accruing due after January 6, 1902, you will become, by implication of law, a yearly tenant holding on such of the terms and conditions of the expired lease as are not inconsistent with a yearly tenancy. A clause in a lease permitting a tenant to remove, when he quits, all the things he has planted or erected upon the holding, is not inconsistent with a yearly tenancy; and so, when you quit, you will be at liberty to remove all the greenhouses, plants, shrubs, trees, etc., you have erected or planted. It will, of course, be open for your landlord to rebut the presumption that you are a yearly tenant holding upon the terms of the expired lease, but to do this he must bring evidence to support his contention.—K. C. T.]

Contract to relay lawn (W. H. W. G.).—Last May you contracted with a gardener to turf a lawn for you, and on completion of the work you paid him the greater portion of the sum he was to receive for it, and retained the remainder until it could be seen whether the work proved satisfactory. You do not say whether it was a condition of the contract that you were to withhold this portion. If it was not, but was afterwards imported by you, the deduction was illegal, and the gardener could have at once recovered the balance, unless you could have then proved that the work was badly done. You say that the lawn proved unsatisfactory, as some of the turf died, while every part of it was full of rough Grass, Thistles, and weeds. He then offered to relay the turf, but, as the offer was made in mid-winter, you declined it, and you wanted the work done in early spring, and said you should hold the money until the lawn proved to have been satisfactorily laid. He declined this proposal, and so the work remains undone. You ask if you can employ another gardener to do the work, and use the balance you have in hand to defray the expense incurred, and, if that balance proves insufficient, you ask if you can recover the excess from the original contractor? The answer depends upon the terms of the original contract. If there was not a stipulation that you should retain a portion of

the contract price until it could be seen how the lawn turned out, I think you cannot do as you propose. It is, however, evident that the work was badly done, as the weeds and Thistles would not have appeared if proper material had been used, and as the man did not sue at the proper time, I think he cannot now do so with success. You may expend in relaying the balance you have in hand, but I think that if the work of relaying costs more than that balance, you cannot recover the excess from your original contractor.—K. C. T.

CORRESPONDENCE.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow these rules: All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF GARDENING, 17, FURNIVAL-STREET, HOLBORN, LONDON, E.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper, and not more than three queries should be sent at a time. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, queries cannot always be replied to in the issue immediately following the receipt of their communication. We do not reply to queries by post.

Naming fruit.—Readers who desire our help in naming fruit should bear in mind that several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents simple specimens of fruits for naming, these in many cases being unripe and otherwise poor. The difference between varieties of fruits are, in many cases, so trifling that it is necessary that three specimens of each kind should be sent. We can undertake to name only four varieties at a time, and these only when the above directions are observed.

PLANTS AND FLOWERS.

Raising Myosotis and Alyssum (D. McLeod).—Forget-me-not is easily raised from seed sown now in the open air or in boxes, pricking out the seedling plants afterwards. Alyssum saxatile can be raised freely in the same way. We are supposing that you have no plants. If you have any, division is a good way of increasing these plants.

Soot-water (Edith Chalmers).—So long as the water is much discoloured by frequent disturbance of the beetles the water is so long in their virtue in the soil. When the water is no longer darkened it is evident the carbon is well exhausted, and a fresh lot of soot may be put in. Soot is such a safe stimulant that its use may be prolonged almost indefinitely, or so long as growth is active.

Preparing Quassia extract (R. H. Morebank).—Soak 1 lb. of the chips in a gallon of water for two or three hours, then heat it till it boils. Let it simmer for at least 12 hours, strain, and add 10 oz. of the best soft-soap. Add 10 gallons of water before using. This is the ordinary strength used for destroying green-fly, etc.

Destroying wireworms (Amateur).—These may be caught by burying small slices of Turnips, Mangolds, Carrots, or Potatoes near the plants they are attacking just below the surface of the soil. A small wooden skewer stuck into each bait renders them easier to handle and find. They should be examined every morning. Small pieces of Rape cake are also very useful for the same purpose.

Sweet Pea flowers falling to open (S. C. R.).—If all the buds are like those sent we can only suggest that a check be made in the direction of the buds in all probability the time the flower-buds were formed. On check, as excessive dryness at the root, and that frequently occurring, has taken place, then we may look for the fault in the soil being insufficiently charged with lime. Water with lime-water for a time, and give a top-dressing of soil mixed with bone-meal.

Carnations failing (Jack).—In all probability the most satisfactory way to treat your Carnations will be to throw them away, for it is too late to propagate any except the Malmansons, and, as they are all in a bad state, you cannot obtain good cuttings. You might, however, plant them outdoors and keep them watered, when, if any recover and push out new shoots, they may be layered. If these are potted when rooted and wintered in a cool-house, they will give you a supply of young plants to start with next spring.

Primula obconica poisonous (Geddes).—It is quite true that in some few persons who have some constitutional predisposition to skin disease the handling of this plant has caused severe irritation. We have handled this plant for many years without any ill effects of any kind, but, as stated above, the results in a few cases may be undesirable. In such cases, then, it is not wise to have anything to do with *P. obconica*, but we have known *P. sinensis* act in a similar way. *P. obconica* is too charming a plant when in flower for anyone to destroy.

Increasing Gloire de Lorraine Begonia (S. C. R.).—You ought to have cut down your plants immediately flowering was over below where the first blooms were produced. In a short time young shoots will be pushed out from the base of the plant, and when these are from 1 1/2 inches to 2 inches long they form the best of cuttings. Cut them off close to the main stem and dibble them into well drained pots of sandy soil, water through a fine rose, and stand in a close propagating-case in the stove. The cuttings will root in about three weeks, when they should be potted off singly into small pots.

Planting flower garden (J. H.).—As your side border is but 3 feet wide, we should prefer to plant that with Antirrhinums at the back, Asters and Stocks mixed in the middle, and Phlox Drummond at the front. Plant the broad border, No. 2, with Dahlias behind, then Feat-

VEGETABLES.

SEVERE MAY FROSTS.

This year there has been a second winter in the matter of late severe frosts and cold, cutting winds, and the influence of such unusual weather is manifested in the present state of garden and field crops. Almost every tender crop bears the impress of cold weather in the slow and scanty growth which has been made. In the 14th of the month 6 degs. were recorded, tender Potato tops, Strawberry flowers, and Asparagus heads showing unmistakable evidence of the extreme cold. There has been not one morning up to the middle of May on which there has been no frost, the one exception being Sunday the 11th. Frosts of the same severity, following a period of mild weather, would have inflicted greater havoc, and the hardening influence of the continued cold winds saved many crops. Potatoes only emerging from the soil have suffered the most. The value of shelter has been amply demonstrated this spring, for tender vegetation in the open has suffered badly, while under walls and hedges much less damage has been inflicted. Such a winter is a period to be dreaded, because the season then is so far advanced that protection is entirely out of the question. Where a quantity of bedding and pot-plants are drafted into sheltered corners outdoors, both with a view to the relief of the glass structure and for the purpose of hardening them for open air use in summer, much anxiety is caused in such a season. In suburban and town gardens it is customary to commence the summer bedding by the middle of May, but it can not be admitted the cold and frost are not so severe as in the more open country gardens. The result of this extreme cold must of necessity both retard and diminish the output of many a garden in its outdoor crops. Potatoes, in particular, must be late, and if the tops are repeatedly frosted the yield is lessened in a serious degree. Beans and Marrows, too, will not repay early sowing this year.

W. S.

VEGETABLE MARROWS.

(Reply to "C. H. A.")

The seed of Vegetable Marrows should be sown in April under glass in a temperature of 65 degs. or 70 degs. As soon as the rough leaf is formed pot off singly into 6-inch pots, and return the plants to a frame until they become established. Gradually harden them off and plant out in the open air towards the end of May. Hamlights should be placed over them for a few days after planting. Do not keep on the lights too long, as the plants are liable to be attacked by mildew. When well established the shoots may be stopped to make them throw out from six to eight leading stems. These may be led off in different directions to form the plants. After the plants reach a considerable size a fruit will be formed under each leaf, and if the Marrows be cut young and none left to ripen seeds, the plants will go on bearing until October unless cut off by frost. If

planted on rich soil very little water will be required; but if the soil is poor and sandy frequent watering is necessary, with an occasional soaking of liquid-manure. On no account allow the plants to flag, as then they will be attacked by mildew, which will soon destroy them. A simpler way for those who have no glass is to sow the seeds in the ground about the middle of May. A bell-glass may be put over the seeds to assist germination, and the plants, when well established, will continue to fruit during the summer and well into the autumn.

Rapid growth, too, is important, hence the soil can hardly be too rich. If grown slowly the Marrow is apt to be tough and bitter. On a rubbish-heap the Vegetable Marrow will do well and fruit abundantly. It is also a capital plant for filling any nook or corner, covering dead walls and fences, scrambling over out-buildings, or growing in any out-of-the-way place. Among varieties the best are the long White and Pen-y-Byd.

CABBAGES BOLTING.

There seems still to be a good deal of uneasiness amongst small Cabbage-growers with respect to the tendency which exists on the part of their plants sown in the autumn and planted later to bolt off to flower in the spring instead of hearting in. It does not seem to be known that certain varieties are better suited for spring sowing, and so treated do not bolt. It does seem as if these varieties still had in them something of the annual character of the original species, or may, to secure certain nice flavour, have been the product of crosses with one or other of the Cole-worts. If these latter be sown in the autumn they all bolt to flower. If they be sown during spring or summer they heart in capitally. If any readers find that any variety shows a constant tendency to bolt from autumn sowings, they should not so employ the variety again. There is plenty of good reliable varieties that will not so bolt. There is reason sometimes to assume that too early sowing in the autumn may govern bolting. I do not think evidence is strong enough to justify that assumption to any material extent. Still, it is very easy for anyone to test its merits by making a sowing the last week in July, and a second the third week in August, which is late enough to secure good plants to put out in October for spring hearting. Even in these cases some allowance must always be made for a trifling proportion of what are termed "rogues" being among the plants. These find their way into good stock. Still, in pulling plants from a bed, any that seem to be a trifle coarse or not true should be avoided or thrown away. I have never yet seen a breadth of Cabbage, large or small, of however good stock, which did not have in it a few plants at least that were not quite true to character.

I have been just looking over a most interesting trial of autumn-sown Cabbages growing on an open, exposed site on a deep but not rich bed of sand. The trial includes its varieties got from leading seed firms, and of each one two sowings were made, viz., July 24th and

August 16th, the respective plantings being done on September 25th and October 16th. One half the plot was first planted and the second one had the first rows continued right across. These were put out 40 plants in each row, so that the total number put out in the trial was 1,440, quite a sufficient number. Of the first planting only 11 plants out of 720 bolted, and these were distributed over six varieties—a proportion too trifling to merit consideration; yet of the second planting there was not a single bolter. That fact was made all the more apparent because with the second planting some 300 additional plants were put out to fill the space the trial left unoccupied. If, therefore, there was in respect of non-bolting a trifling gain in favour of the August sowing and October planting, it is worthy of note that the proportion of bolters in the first planting was very trifling, and in the second there was material gain in earliness, hearts being ready to cut fully a fortnight before any from the second planting were ready.

PEAS FOR EXHIBITION.

It used often to be written concerning Potatoes that exhibition varieties were of no value for domestic uses. It is so far unfortunate in relation to Potatoes that there are some varieties, notably the old International Kidney, Mr. Breese, Red Kidney, and Edgote, Purple Kidney, that are really bad cookers, and should never be grown for any purpose. Still, the majority of Potatoes are equally good for show or for eating, and, therefore, the reflection on those referred to has little force. But with Peas, we know of no variety that is not good for show, but is also equally good for the table, for, apart from appearance, judges, if in doubt as to the merits of one dish or variety over another, usually open pods and taste the Peas, and flavour then materially influences the decision. But we have now such a wealth of splendid Peas, fine in pod, well filled, good in colour and in flavour, that there is little difficulty in growing and exhibiting of the best. Generally, it is found that the requirements of exhibition Peas are: pods of equal size, long, well filled, yet young and fresh, pods and peas of good deep green colour, the former carrying a nice, powdery-like bloom, and the latter tender and of good flavour. There are many varieties of Peas which give these requirements naturally if good culture has developed them. To preserve the "bloom" on the pods, care should be taken not to run against them in passing up and down between the rows, but also, when gathering, only the stem should be handled, the pod being carefully preserved from marks. Any rust marks or abrasion on the pods are defects in exhibition Peas, although they may not in the least affect their cooking qualities.

To produce fine, clean, handsome pods, high-class culture is requisite. No matter what the variety or the season, real show pods cannot be obtained unless the soil be deeply trenched, liberally manured, and the plants freely supplied with water during hot, dry weather. In addition, also, it is a good

plan to syringe the rows with clean water in the evening, as by so damping the growth spider or thrips, both troublesome pests, are kept in check. A mulch of long manure some 18 inches wide laid along on each side of rows of Peas does great good in retaining moisture. No matter what the variety, the seeds should always be sown thinly. The leading vegetable exhibitors put in their Peas fully 6 inches apart, and in drills that have been thrown out with a spade 7 inches to 8 inches wide. So treated the plants later get plenty of root and leaf room, and thus escape many of the troubles which affect Peas that have been thickly sown. Good varieties to produce fine deep green pods are Gradus, Early Giant, Duke of Albany, Edwin Beckett, Prizewinner, The Gladstone, Sharpe's Queen, The Duchess, and Alderman, but there are others also. Probably the Duke of Albany and The Gladstone are more generally grown, but all these are first rate. A. H.

NOTES AND REPLIES.

Early v. late planting of Brussels Sprouts.—No green vegetable is so profitable in the garden as this. Six months for a crop to be in use is a long time. Some may ask how this can be accomplished. The answer is, sow early under a handlight, an odd light, or in the open border, plant out early in June in highly cultivated land that has been worked deeply early in the year and allowed to settle, in rows 2½ feet apart and 2 feet from plant to plant. Some years ago I planted early in June and at

the soil? Neglecting to take these simple precautions invariably leads to an attack being set up the following season, as the spores lie dormant during the winter months, either in

the soil or on the woodwork, and only need a congenial atmosphere to call them into being. As your other plants are as yet free from the disease, you may possibly keep them so by

Rock Garland Flower (*Daphne rupestris*). (See page 201.)

the end of July, with the result that both lots came in at one time, and since that I have given up planting late. Last year my main crop was put out in June. The plants grew 3 feet high, with sprouts from the ground. From these I commenced gathering nice close sprouts early in October, and continued all through the winter till the middle of April. Some plants I could not get out till a month later from want of land. These did not give two-thirds the sprouts. My best selection was Market Favourite. I am no believer in sowing on a hotbed or in heat at all. My plants are ready to go out in time enough by sowing on open border and putting a glass over. J. CROOK.

Tomatoes falling.—I send you by post a Tomato plant which puzzles my gardener. It was one of a long row in a greenhouse, planted in a sort of sleep trough. Every other plant is looking healthy and strong. I cannot understand why the one I send you has gone off. Last year I lost several plants in the same mysterious way, and I shall be much obliged if you can assign any reason?—W. FORESTER MILLS.

[The Tomato plant submitted appears to be suffering from an attack of the Potato disease (*Peronospora infestans*) or an allied form of it, and your last season's losses doubtless resulted from the same cause. It is somewhat difficult to assign a reason for an outbreak occurring so early in the season, but the following queries may perhaps assist you in clearing up the matter: Did you clear out the soil in which the infested plants were grown last season? Also, was the woodwork and glass well washed with warm, soapy water, and did the walls and all portions of brickwork receive a thorough coating of hot lime wash after the same manner

maintaining a dry, warm, buoyant atmosphere in the house (the opposite conditions are all in favour of the germination of the spores), and paying particular attention to ventilation. On warm, sunny days admit air both at the front and apex, but if the wind is cold and in the east keep the front lights closed until such

lime as warmer conditions prevail. Also, if you have Potatoes planted in proximity to the front ventilators, keep the latter closed together until the crop is lifted. The soil

attached to the roots of the plants submitted is not exactly suitable for Tomatoes, as peat is not an essential; but this would not, in our opinion, have anything to do with the disease complained of.]
